It appears by Corol. 2. Problem XLI. of Clark's Mechanics, that if TR be multiplied by some constant quantity as b , the product will expound the weight with which the vouffoir dm must be charged, in order to preserve the equilibrium of the arch. Now as the solid part of the arch is comprised between two vertical planes, it is evident, that the faces of the vouffoirs, which are the trapezia $gdmn$, or $gdm p$, may serve to expound the weights of the vouffoirs; therefore $gdm p$ will always be equal to $\frac{a^3 b \dot{y}}{u^3}$. But by reason of the similar sectors Bdm ,

$Bg p$, we have $B\dot{d}^2(a^2):B\dot{g}^2-B\dot{d}^2(ss-aa)::Bdm$

$\left(\frac{a\dot{y}}{u}\times\frac{a}{2}\right):dg p m\left(ss-aa\times\frac{\dot{y}}{2u}\right)$ hence $s^2-a^2\times$

$\frac{\dot{y}}{2u}=\frac{a^3 b \dot{y}}{u^3}$, and $ss-aa=\frac{2a^3 b}{u^2}$, from whence we

get $s=\frac{a}{u}\times\sqrt{2ab+u^2}$, this, when $u=a$, becomes

$ff=2ab+aa$, consequently $b=\frac{ff-aa}{2a}$; let this

value of b be substituted in the equation $s=\frac{a}{b}\sqrt{2ab+u^2}$; it becomes $s=\frac{a}{u}\times\sqrt{f^2-a^2+u^2}$;

draw the ordinate gI to the axis OB ; then will BI be a fourth proportional to Bd, BF, BG , and is therefore equal to $\sqrt{ff-a^2+u^2}$; hence this construction:

Take the key-stone $QP V Z Q$ at pleasure, the lines VZ, PQ , tending to the center B . From A , draw the horizontal line CAT ; and from the

center B , with BO , as radius, describe the circular arch OC , meeting TAC in C ; take any point at pleasure, as d , upon the intrados, and make AH equal to the perpendicular distance of d from the radius BK . Draw CH , make $BI=HC$; and from I , draw Ig , meeting Bd produced in g , which will be one point in the required extrados; in the same manner other points may be found, by which the extrados OgX may be determined.

If AD (Plate XXII. fig. 3.) be a given arch, whose extrados is pTN , axis Ab , semipan ba , and $A p$ the given height of the vertex of the required extrados from that of the arch; and from A , a right line $\dot{A}MP$ be drawn parallel to the horizontal line ba ; also through any point M , a right line parallel to Ab ; then will $T e$ (Aba being a quadrant of a circle), the height of the extrados above the point e of the proposed arch, be inversely as the cube of the right line ed . But if Aea be the arch of an ellipsis; then having first multiplied the square of ed , by the square of the semi-transverse ba , and the square of the horizontal distance AM , by the square of the semi-conjugate Ab , and subtracted one product from the other, the height eT of the required extrados will be directly as that difference, and inversely as the cube of ed .

If the proposed arch be the curve of an hyperbola; then having multiplied the square of the de s by that of the semiordinate ba , and the square of the horizontal distances AM , by the corresponding part Ab of the axis, and taken the sum of those products, the ratio of the heights eT will be compounded of the direct ratio of those sums, and inverse ratio of the cubes of the heights de . M. Parent's *Essais & Recherches de Mathematique*, vol. 3. p. 168.

PROBLEM. II. To determine the thickness of the piers necessary to sustain in equilibrio the part of a proposed semi-circular arch.

SOLUTION. Let SZ (Plate XXII. fig. 4.) be one of the required piers of the semi-circular arch, whose half is represented by $BEDG$. Through L , the middle of EC , draw MK parallel to ZA , and produce PZ to M . Let fall LV perpendicular upon AB ; and from L draw LO at right angles to LA , meeting the perpendicular PO in O . From Q , the center of gravity of the vouffoir CE , let fall QR perpendicular upon the base SP of the pier, bisect PS in T ; call LK or KA , a , LA , b , BV , c , ZP , d , ZB or RS , g , PS , y ; then will ML or MN be equal to $c+y$, and $MP=a+d$; consequently $NP=a+d-c-y$. Put $a+d-c=f$, then $NP=f-y$, and $PR=y-g$. If for the surface of the vouffoir CG , or its equal CE , we put n^2 , then will

$\frac{bn^2}{a}$ express the force of the vouffoir in the direction LO . By similar the triangles LKA, NOP

we have $LA(b) : LK(a) :: NP(f-y) : PO$
 equal to $\frac{af-ay}{b}$, which being multiplied by $\frac{bn^2}{a}$,
 gives $n^2 f - n^2 y$ for the force acting at right angles
 upon the arm PO of the lever RPO , whose
 center of motion is P ; therefore, by the well
 known properties of the lever, $n^2 \times \frac{dy^2}{2}$,
 are the respective forces acting at the points T, R ,
 in a direction perpendicular to the horizon; and
 consequently $nnf - nny = \frac{d^2 y}{2} + n^2 y - n^2 g$. From
 this equation, by completing the square and pro-
 per reduction, we get $y = \sqrt{\frac{2n^2 f + 2n^2 g}{d} + \frac{4n^4}{d^2}}$
 $- \frac{2n^2}{d}$.

When the extrados of the arch BDH (Plate
 XXII. fig. 5.) is terminated by a horizontal line
 QX ; then, having taken $FC=DG$, and drawn
 LO perpendicular to FC , in the middle point L
 as before, and other things remaining still the same,
 put $MP=f$, then by the similar triangles LKA ,
 PON , we have $LA : LK :: PN : PO$, whence
 $PO = \frac{af-ae-ay}{b}$. Now the absolute weight of
 the vouffoir $CWGD$, here supposed $=n^2$, is to
 the force thereof, acting in the direction LO , as
 $LK : LA$ by the nature of bodies resting upon
 inclined planes, and is therefore equal to $\frac{n^2 b}{a}$,
 which, being multiplied by PO , becomes $fn n -$
 $cn n - n^2 y$: and this product must, by the nature of
 the lever, be equal to the weight of the pier $PQRS$,
 multiplied by PT ; hence this equation, $fn^2 - c$
 $n^2 - n^2 y = \frac{d^2 y^2}{2}$, from whence we get $y = \frac{n^2}{d^2} - \frac{n^2}{d} +$
 $\sqrt{\frac{2fn^2 - 2cn^2}{d}}$.

PROBLEM III. To determine the thickness of
 the piers necessary to sustain in equilibrio the parts
 of a proposed semi-elliptical arch.

SOLUTION. Let SZ (Plate XXII. fig. 6.) be
 one of the required piers of the semi-elliptical arch,
 whose half is represented by $BEGD$. From the
 middle of the arch BD , draw LO a tangent to
 that point, and erect the perpendicular LA , which
 produce to A . From L , let fall PO perpendicular
 upon LO ; and through L , draw MLK paral-
 lel to the semi-transverse axis BH . Put $LK=a$,
 $KA=b$, $LA=c$, $BV=d$, $BS=f$, $MP=g$, n^2 for
 the surface of the vouffoir CG , nearly equal to FB ,
 $ZB=y$. By the similar triangles LKA, LMN , we

have $AK : KL :: LM : MN$; whence $MN =$
 $\frac{ay+ad}{b}$, and thence $NP = \frac{gb-ad-ay}{b}$; and again,
 by the similar triangles LKO, NOP , we get
 $PO = \frac{gb-ad-ay}{c}$.

Now the absolute weight of the vouffoir $LFGD$,
 is to its pressure upon FL , as LK to LA ;
 consequently $\frac{cn^2}{a} \times \frac{gb-ad-ay}{c}$, expresses the force
 acting upon the point O , in the direction LO .
 On the other hand, the resistance of the pier SZ
 will be expressed by $\frac{f^2 y^2}{2} + n^2 y$ (PT being equal to
 TS , and P considered as the center of motion of
 the lever OPT): hence, by making the force
 and resistance equal, we shall have $\frac{gbn^2}{a} - dn^2 -$

$$n^2 y = \frac{f^2 y^2}{2} + n^2 y; \text{ and consequently } y = \sqrt{\frac{2gbn^2}{ef} - \frac{2dn^2}{f} + \frac{4n^3}{f^2}} - \frac{2n^2}{f}.$$

PROBLEM IV. To determine the thickness of
 the piers necessary to support in equilibrio the pro-
 posed vouffoirs, when ranged in a right line.

SOLUTION. Upon LF (fig. 7.) the given dis-
 tance between the piers describe an equilateral tri-
 angle LAF ; and divide its base LF , into as many
 equal parts as there are vouffoirs. From A , draw
 through those points of division right lines termi-
 nating in the indefinite right line GI (drawn paral-
 lel to LF , at a given distance therefrom) in the
 points E, C, D , &c. From L draw LO at right
 angles to AD , and from P let fall PO perpendi-
 cular thereon. Produce KL to M , and draw
 AKC perpendicular to LF . Put $KL=a, KA=b$,
 $MP=f$, $LM=y$, and n^2 for the area of $LDCK$.

The triangles AKL, LMN , and NOP , are
 similar; hence $KA(b) : KL(a) :: LM(y) : MN$
 $(\frac{ay}{b})$; and consequently $NP = \frac{fb-ay}{b}$. Again,

$$AL(2a) : AK(b) :: NP(\frac{fb-ay}{b}) : PO$$

$\frac{fb-ay}{2a}$. The absolute weight of $LDCK$ is to
 its force upon the pier SM , as LK to LA ; but
 LA is double to LK . Therefore the force acting
 upon O in the direction LO may be expounded
 by $2nn$, which being multiplied by PO , gives
 $\frac{bfn^2}{a} - n^2 y$; for the force acting upon P at the
 distance PO , which, by the property of the lever,
 must be equal to the force acting upon the point
 D .

D, at the distance of half PS therefrom. But this is expounded by $\frac{fyy}{2}$ hence $\frac{bfnn}{a} - nny =$

$$\frac{fyy}{2}; \text{ and consequently } y = \sqrt{\frac{2bny}{a^2} + \frac{n^2}{f^2}}$$

BRIDGE, in gunnery, the two pieces of timber which go between the two transoms of a gun-carriage, on which the bed rests.

BRIDGE, in music, a term for that part of stringed instruments over which the strings are stretched. The bridge of a violin is about one inch and a quarter high, and near an inch and half long.

BRIDGES, in artillery, machines of various constructions for crossing a river, the most considerable of which are called bridges of boats.

These bridges are made with boats, which are placed at small distances from each other, the whole width of the river, parallel to their lengths, and covered with planks, which rest on pieces of wood, called *poutrelles* or joists, firmly fixed to the boats.

There are bridges of boats of many forts; some are constructed with copper-boats, which in artillery are called *pontons*, and these are carried with an army on carts or drays, made for that purpose; others are constructed with the common boats found on the rivers which are to be passed.

To construct a bridge of boats, the boats are bound together with strong ropes reaching diagonally across their distances, from the head of one to the stern of the other, as is represented in Plate XXIII. fig. 1, and 2. Across these boats are laid the *poutrelles*, and upon them strong planks of deal, which are firmly nailed on; fir-planks are preferred, because that wood is lighter and less brittle than oak.

When the river over which the bridge is to be laid is very rapid, anchors are let down from the cord or cable to which all the boats are fastened; these anchors are first cast into the river, and the cord is then drawn as tight as possible by capsterns on each bank, that the boats may be more securely fixed; these cords or cables are called, in artillery, *cinquenelles*, and are generally one inch and an half in diameter, and an hundred fathoms long.

The boats have also anchors, by means of which their situation is rendered more steady and secure, and capable of making a stronger resistance to the tide or motion of the water.

Fig. 1. in Plate XXIII. shews part of a bridge of boats which is not entirely covered with planks, that the arrangement and distance of the *poutrelles* may appear. The same method is observed in the bridge of boats represented by fig. 2. in the same Plate. This bridge is only for passing small rivers,

Fig. 3. in Plate XXIII. shows a ponton mounted on its carriage or cart.

M. de St. Remy observes in his Memoirs, that the pontons which were in use before the time of the Marquis de la Frezeliere, lieutenant-general of the artillery, (which post he filled with great distinction) not being capable of transporting twenty-four pounders over large rivers, without danger of sinking, because they lay so near the water's edge, contrived others longer and higher, which were capable of transporting the heaviest pieces of artillery over any river, without danger of the like inconvenience. The principal dimensions of these boats, according to this author, are as follow:

Their height is 2 feet 9 inches.

Their width 5 feet 6 inches.

Their length 18 feet 6 inches.

The *poutrelles*, which are fir, as well as the planks with which they are covered, are 22 feet long, four feet and an half wide, and of a proportionable thickness.

The planks are 14 feet long, 13 inches wide, and 2 inches thick.

The distance between each boat, or ponton, ought to be 9 feet.

Besides the bridges already mentioned, which are most common, there are yet others called *ponts volants* or *flying bridges*. These are sometimes boats, joined together by strong ropes, and frequently with chains, upon which a sufficient number of *madriers*, or planks, are disposed, so as to make a platform proper to receive cannon, and on which they may be fired, either to oppose or favour the passage of a river. An *epaulement*, or side-work of defence, is also made musket-proof to cover the men who occupy this bridge and play the cannon.

The *pont volant* is also sometimes a bridge made of one great boat, or several smaller boats, which floating, is drawn across a river, by means of some machines or cords which communicate with the opposite side.

Sometimes the *pont volans* is composed of two boats joined together by a flooring of *poutrelles* or *madriers*, and surrounded with a rail or balustrade, having also one or more masts, for supporting a cable, one end of which is fastened to a roller, or windlafs, fixed in the middle between the two boats sterns: the other end of the cable is fastened to an anchor, sunk at a considerable distance higher up the river: the cable after passing between two parallel beams, reaching from one mast-head to the other, is supported at proper distances, by boats, to prevent it from sinking: by this contrivance the bridge becomes moveable from one side of the river to the other, like a pendulum, without any other help than the rudder: for as soon as the boats heads are directed obliquely across the stream, the force of the current

current continually impresses that part of the bridge, and urges it towards the other shore. These bridges consist also sometimes of two stories, for the quicker passage of a great number of men; or, that the cavalry and infantry may pass at the same time.

A bridge is also called a *pont volant*, which is made over small rivulets four or five fathoms wide, and composed of two bridges, one laid on the other, in such manner as that the upper one may be thrown forward by means of cords and pulleys properly disposed in the lower. These bridges can never be large, because the weight of the upper-bridge, when it runs out, or is thrown forward, would, if not very small, break all its fastenings to the under-bridge, and so the whole machine would be rendered useless; and for this reason they are never used but for passing ditches, fosses, or rivulets not wider than four or five fathom.

Besides these, there is yet another sort of pont volant, made use of in war on several occasions, called a *raft* or *float*. This is made of many rafters, or pieces of timber, which together form a kind of floor; these are covered with planks, or strong madriers, and a certain number of empty casks are made fast to the ends of the rafters, the better to support the float, and whatever is placed upon it. These floats are used to transport troops, cannon, &c. over rivers.

BRIDLE, in the manege, a contrivance made of straps or thongs of leather and pieces of iron, in order to keep a horse in subjection and obedience.

BRIDLE-Hand is the horseman's left hand, the right hand being the spear or sword-hand.

To swallow the BRIDLE, is said of a horse that has too wide a mouth, and too small a bit-mouth.

BRIDLE, *Frænum*, in anatomy. See the article FRÆNUM.

BRIDLES, in the marine, the upper part of the moorings laid in the king's harbours, to ride ships or vessels of war. See the article MOORINGS.

Bowline-BRIDLES. We have explained under the article Bowline, that the use of that rope is to bind the weather-edge, or the edge next the wind, tight forward, when a ship has her sails properly trimmed for a contrary wind; for as the current of air at this time is nearly parallel to the surface, the ridge of the sail into which the wind or current of air enters, must of necessity be shaken by it, unless it is fastened to prevent it: but as a single rope has been found not so convenient for this purpose, as acting only upon one part of the ridge of the sail, bridles were therefore applied, i. e. two or three additional parts, represented in Plate XXII. fig. 1. where A is part of the weather-side of a top-sail, aa the upper-bridle, bb the middle, and cc the lower-bridle, d part of the bowline, into which they are united, drawn tight.

BRIEF, in common law, a writ whereby a man is summoned or attached to answer any action.

It is called brief because it is couched in a few words, without any preamble.

BRIEF is also used for a writing issued out of any of the king's courts of record at Westminster, whereby something is commanded to be done, in order to justice, or the execution of the king's command.

BRIEF is also taken for a letter-patent, granting a licence to a subject to make collection for any public or private loss, as briefs for loss by fire, to be read by ministers in churches, &c.

BRIEF is likewise an abridgement of a client's case, wrote out for the instruction of counsel, on a trial at law.

Apostolical BRIEFS, letters which the pope dispatches to princes, or other magistrates, relating to any public affair.

BRIG, or BRIGANTINE, in the marine, a merchant-ship of two masts. The term brigantine is not universally confined to vessels of a particular construction, but is variously applied by the mariners of different European nations to a peculiar sort of ship of their own marine.

Amongst English sailors, this vessel is distinguished by having her mainmast set fore and aft, or lengthways; whereas the mainmasts of larger ships are hung athwart, or at right angles with her length, and fastened to a yard that hangs parallel to the deck; but here the foremost edge of the mainmast is fastened in different places to hoops that go round the mainmast, and slide up and down on it, as the sail is to be hoisted or loosened; it is extended by a gaff above and a boom below. See the articles BOOM and GAFF.

BRIGADE, in the military art, a party or division of a body of soldiers, whether horse or foot, under the command of a brigadier.

BRIGADE-MAJOR is an officer appointed by the brigadier, to assist him in the management and ordering of his brigade.

BRIGADIER, in military affairs, the officer whose degree is the next above that of a colonel.

There are brigadiers of infantry, cavalry, and dragoons. The duty or office of the brigadier is to command a corps consisting of several regiments, called a brigade.

The brigades of infantry commonly consist of four or five battalions, and sometimes six; and the brigades of cavalry of eight or ten squadrons.

The brigadiers are on duty each one day successively, and by turns: their service consists in assisting the general officers, who are in a rank above them, in whatever concerns the order and security of the camp possessed by the army, and to execute the orders they receive concerning these affairs.

The brigadier is not a general officer, but appointed to command only his own particular brigade,

gade, and not any other distant corps of the army.

BRILLIANT, in a general sense, something that has a lucid and bright appearance.

BRILLIANT Diamonds. See the article **DIAMOND**.

BRIMSTONE, in natural history, the same with sulphur. See **SULPHUR**.

BRIMSTONE-WORT, in botany. See **PEUCE-DANUM**.

BRINE, water replete with saline particles; or pickle. See **SALT**.

BRINGING-TO, in navigation, the act of stopping a ship in her progress at sea or near the land.

It is done by disposing the sails in such a manner to the direction of the wind, as to counter-act each other; so that while some of them impel the ship forward, the rest force her to retreat.

The use of bringing-to is either to speak with some other ship at a distance, which is advancing, to found, or to wait for day-light, or clear weather, in case of running on land, rocks, shallows, &c. supposed to be near.

BRINGING-BY-THE-LEE, in navigation. See the article **BROACHING-TO**.

BRISTOL-WATER. These waters are the fourth in degree amongst the waters which are esteemed warm. The waters of Bath are the first, Buxton the second, and Matlock the third.

The diseases in which Bristol waters are properly prescribed, are internal hæmorrhages and inflammations, blood-spitting, dysentery, an immoderate flux of the meneses, and purulent ulcers of the viscera; hence in consumptions, the dropsy, scurvy with heat, stone, gravel, strangury, the habitual gout, scorbutic rheumatism, diabetes, slow fevers, atrophy, venereal disease, cancer, gleets in both sexes, king's evil, &c. in all these disorders, Bath-waters are not only improper, but hurtful; they rouse the too languid, and quicken the too lazy circulation; they allay the heat, and restrain the too rapid motion of the blood. The former attenuate the choleric, and the latter impregnate the phlegmatic. In short, Bath-water seems to be adapted to the maladies of the stomach, guts, and nerves; Bristol, to those of the lungs, kidneys, and bladder: again, Bath-waters are at variance with a milk course; and the Bristol can never be judiciously directed, but when they may be joined with reason and success.

The Bristol-waters are taken medicinally only during the hot months, as from April to September.

BRITANNICA, among the ancient physicians, the name by which they called the great water-dock; a powerful astringent, which they prescribed in hæmorrhages, and other fluxes. See **LAPATHUM**.

BRITTLENESS, that quality of bodies on account of which they are denominated brittle; or which subjects them to be easily broken.

BRIZA, in botany, a genus of triandrious plants, whose corolla is composed of two valves; the lower valve is of the size and shape of the cup; the upper valve is small, plane, and roundish, shutting up the hollow of the other. It contains three hairy filaments topped with oblong antheræ; the corolla serving in the place of a pericarpium, incloses the seed, and when ripe drops it out. The seed is single, small, roundish, and compressed.

BRIZE, in husbandry, denotes ground that has lain long untilld.

BROACHING-TO, in navigation, the act of bringing a ship's side to the windward, when she had been steering more before it.

As a ship can carry much more sail before the wind than when she bears her side to it, this is a most pernicious event, which is often attended with very fatal consequences; such as rending the sails to pieces, carrying away the masts, and even, perhaps, overturning the ship; it is occasioned either by the negligence or incapacity of the men who steer.

It is easy to conceive that, when the current of air is acting nearly end-ways on a ship as she divides the fluid, that the pressure of the wind upon the masts must be considerably diminished as she flies from it; and that if she carries a great sail at this time, it can only press her fore-part lower down in the water: but if, when carrying a great weight of sail, her side is suddenly brought to the wind, the whole force of it must pour like a torrent into the cavities of her sails, and the masts thereby unavoidably pressing, like a lever, on the hull sideways, they must go near to overset, if the sails are not immediately reduced, which is hardly possible to be done in so short a time, or the masts may be carried away, or the sails torn to pieces, by which she may recover her situation.

The difference between broaching-to and bringing-by-the-lee may be thus understood. Suppose a ship, with all sail set, is steering north, and having the wind S. S. W. then is west the weather, and east the lee-side.

If by a neglect of the helmsman her head is brought round to the westward, so as that her sails are taken all aback before he can make her return to the course from which she had deviated, she has broached-to.

If otherwise, her head is from the same cause directed so far eastward as to lay the sails aback, she is said to be brought-by-the-lee. See **ABACK**.

BROAD, an appellation given to things whose breadth bears a considerable proportion to their length.

BROADSIDE, in a sea-fight, the whole discharge

charge of the artillery on one side of a ship of war on her enemy.

BROCADE, or **BROCADE**, a stuff of gold, silver, or silk, raised and enriched with flowers, foliages, and other ornaments, according to the fancy of the merchants or manufacturers.

BROCCOLI, in gardening, the Italian name for a species of the brassica or cabbage, much cultivated in England for culinary use in winter: there are two sorts commonly raised, and distinguished by the names of purple and white broccoli. These plants are propagated by sowing their seeds; the season for which is the latter end of May or beginning of June on a bed of good earth, and kept well-watered in dry weather. When the plants are got about three inches high, they should be transplanted into beds at about four inches asunder; here they may remain till the latter end of July or beginning of August, when (taking if possible the advantage of moist weather) they may be planted out where they are to remain, at the distance of three feet row from row, and two feet in the rows, and placed alternately. The soil in which they should be planted ought to be rich, rather light than heavy: towards the end of December, if the weather is not severe, they will begin to show their small heads, which, especially at their first appearance, are not unlike cauliflowers. These heads should be cut off before they run to seed, with about four or five inches of the stalk, and a great number of sprouts or side-shoots, produced from the stem, will succeed them, and continue fit for eating till April: though they are not so large as the former, yet they are equally as well tasted, if not superior in flavour.

In order to save good seeds of broccoli, there should be reserved a few of the largest heads to run up to seed, observing to strip off the side-shoots, leaving only the principal head to flower, with this precaution, not to let any other plant of the same genus be near them when in blossom, as the effluvia might occasion a degeneracy. If this practice is duly observed, the sort may be preserved in perfection many years, and the seed as good as those procured from abroad.

Another sort, called the brown or black broccoli, is by many greatly esteemed, but is much inferior, in respect to the palate, to the former; therefore, the only recommendation which can be given to it is, that it is much hardier, and will bear the severity of winter better; and is on that account a good substitute when the other sorts have failed. This sort will grow very tall, and therefore should have the earth drawn up to their stems, as they advance in height. This does not form heads so perfect as the Italian broccoli, the stems and hearts of the plants being the parts which are eaten. For the general characters of the broccoli, see the article **CABBAGE**.

BROCK, among sportsmen, a term used to denote a badger.

A hart too of the third year is called a brock, or brocket; and a hind of the same year a brocket's sister.

BROKEN-BACKED, in the marine, a ship is said to be so when either by her weakness, age, or some great strain, she is so loosened in the middle as to droop at each end. See **KEEL**, **CAMBERING**.

This is more frequent in French ships than English or Dutch, owing partly to the floor not being carried sufficiently forward and aft, or farther from the middle towards the ends, and partly from being obliged frequently to have a great weight in both ends when they are empty in the middle, at the time of delivering one cargo and taking in another.

BROKER, a name given to persons of several and very different professions, the chief of which are exchange-brokers, stock-brokers, pawn-brokers, and brokers, simply so called, who sell household furniture and second-hand apparel.

BROMELIA, a genus of hexandrous plants, resembling some sorts of aloes. From the center of the plant arises the flower-stalk, the lower part of which is garnished with leaves placed alternately at every joint. The upper part of the stalk is furnished with flowers set in a loose spike quite round; these have three narrow herbaceous petals, sitting upon the germen, and within are six slender filaments topped with oblong anthers, which with the style are shorter than the petals. These flowers in their native country are succeeded by oval seed-vessels having a longitudinal partition, in the center of which are fastened several smooth cylindrical seeds. These plants grow naturally in divers parts of the West-Indies, and are propagated by seeds. To this genus Linnæus has added the ananas or pine-apple.

BRONCHIA, in anatomy, the ramification of the trachea.

The bronchia, in their origin, are formed of imperfect annuli, and in their progress of cartilaginous and membranous frustæ, very curiously connected and joined together. These have their origin from the trachea; and after being subdivided into innumerable ramifications, finally terminate in those small vesicles which form the greater part of the substance of the lungs. These vesicles have interstices all the way between them, and adhere, as it were, to the branches of the bronchia, in the manner of clusters of grapes. See the article **LUNGS**.

The word is Greek, *βρογχία*, which signifies the same thing.

BRONCHIAL ARTERY, a vessel allotted to the nutrition of the lungs.

It rises sometimes single, sometimes double, sometimes

sometimes triple, from the aorta and intercostals, and adheres every-where firmly to the bronchia.

BRONCHIAL-VEIN arises either from the intercostals, or from the vena azygos; accompanies the artery, and divides into the same number of branches with it. As the artery brings blood to the bronchia for the nutrition thereof, and of the vessels of the lungs, so the vein carries off the blood again to the cava, where it soon terminates.

BRONCOCHELE, in surgery, a tumour arising in the anterior part of the neck, from the resisting flatus or air, some humour or other violence, as straining in labour, lifting of weights, &c.

The word is formed from the Greek, *βρογχος*, the wind-pipe, and *κηλη*, a tumour.

BRONCHOTOMY, in surgery, an incision made in the aspera arteria, or wind-pipe, which is necessary in many cases, and especially in a violent quinsey, to prevent suffocation from the great inflammation or tumour of the parts. It is also called laryngotomy and tracheotomy.

The word is formed from the Greek, *βρογχος*, the wind-pipe, and *τομή*, to cut.

There are several methods of performing this operation; but that which exceeds the rest, as being most easy and expeditious, and occasioning the least wound and pain to the patient, is by an instrument consisting of a small tube, in which is contained a triangular needle called a trochar. This instrument is so managed, as to pass through the middle of the trachea by one push; and after drawing out the needle from the tube, the latter is left in the wound, till the patient recovers. Bronchotomy should be performed in time, while there is sufficient strength and hopes of the patient's recovery; for when the patient is spent, it is usually performed in vain. If a drowned person has but just expired, or not continued long under water, the most certain and expeditious way of recovering him, will be by opening the trachea with such instrument as is nearest at hand, and afterwards to inflate or blow into his lungs either with the naked mouth, or with a tube.

BRONCHUS, *βρογχος*, in anatomy, the aspera arteria, or wind-pipe, which reaches from the larynx to the lungs.

BRONTIÆ, *Thunder-Stones*, in natural history, the same with the belemnites. See the article **BELEMNITES**.

BRONTIUM, *βροντίον*, in Grecian antiquity, a place underneath the floor of the theatres, in which were kept brazen vessels full of stones and other materials, with which they imitated the noise of thunder.

BRONTOLOGY denotes the doctrine of thunder, or an explanation of its causes, phenomena, &c. together with the presages drawn from it. See **THUNDER**.

The word is formed from the Greek, *βρονη*, thunder, and *λογος*, a discourse.

BRONZE, a compound metal, two thirds of which consists of copper, and one third of brass.

BRONZING, the act of colouring by metal-line powders, plaster, or other buits and figures, in order to make them appear as if cast of bronze, copper, or other metals.

The old method of using a cement in bronzing was, to mix the powders with strong gum-water, or isinglass size; and then with a brush, or pencil, to lay them on the subject; but the artists at present use the japanners gold size: and proceed in all respects in the same manner as in gilding with the powders in other cases. See **GILDING**.

BROOK-LIME, in botany, a herb which produces white, fibrous, creeping roots. The stalks, which arise from the roots, are thick, succulent, and smooth, emitting roots from their joints, whereby they spread and propagate. The leaves are oval, smooth, flat, succulent, and of a dark green colour, standing opposite. The flowers come out in long bunches from the wings of the stalk; they are monopetalous, and of a bright blue colour, resting on short footstalks; these flowers are produced a great part of the summer, and are succeeded by cordated seed-vessels, filled with roundish seeds. This herb grows naturally in brooks and streams of water in many parts of England; it has no remarkable taste, but is preferred to other more acrid antiscorbutics, as it abounds with such parts as to enable it to abrade and clear away those little viscidities that obstruct the capillaries, and occasion scabs and blotches. The dose of the juice is four ounces, but it is best mixed with the juice of oranges, and then it may have a very good effect in hot feurvies. It is also diuretic, and a great cleanser of the viscera, which gives it frequently a place in antiscorbutic and deobstruent compositions. This plant is a species of the veronica, though, by some authors, classed with the anagallis, and called also beccabunga.

BROOM, *Genista*, in botany, a shrub which grows naturally upon open heaths, &c. in many parts of England; the root is hard, woody, tough, yellow, and hath crooked fibres; the stalks are slender, woody, and about two feet high, sending out many slender branches; these are angular, green, and tough, and furnished with small, hairy, dark-green leaves, sometimes growing three together, and sometimes single; the flowers that grow thereon are of a bright yellow and papilionaceous, with crooked stamina and saffron-coloured apices, to which succeed flat broad pods, which are blackish when ripe, containing several flat, hard, kidney-shaped seeds.

Broom is extremely pernicious to arable and pasture land, and therefore ought by all means to be rooted out, which is the only method of killing it; on

bar-

barren grounds, indeed, it is a good improvement ; for, besides its use as fuel, it makes an excellent and lasting thatch, if well laid on.

This plant is intensely bitter, and the leaves, tops, and branches, decocted in wine or water, are useful in dropsies, and all obstructions of the kidneys and bladder ; for they partly purge off the ferous humours by stool, and partly by urine.

Many gather the yellow buds of this plant, and pickle them with salt and vinegar, in the same manner as capers, from which they are not then to be distinguished. The flowers are most in use, and are accounted splenetic, nephritic, and hepatic.

Butcher's Broom. See RUSCUS.

Spanish Broom. See SPARTIUM.

BROWALIA, in botany, an annual didynamious plant, which usually grows about two feet high, and spreads out into lateral branches on every side of the stalk : these are furnished with oval entire leaves, ending in a point, and supported by short foot-stalks. Near the extremities of the branches the flowers come out singly upon long pedicles, which arise from the wings of the leaves, each flower having a monophyllous tubulated calyx indented in five parts ; from the center of which arises a monopetalous funnel-shaped corolla, which is crooked and bent downward ; the top of the tube is spread open, and the brim is labiated. In the center is placed an oval germen, which afterward becomes an obtuse unilocular capsule, divided into four segments at the top, containing several small seeds. The flower is of a bright blue colour, sometimes inclining to a purple, or red, and often there are flowers of three colours on the same plant. The seeds of this plant should be raised in hot-beds in the spring, and may in June be transplanted into the natural ground.

BROW, or **EYE-BROW**, the hairy arch extended over the orbit of each eye.

BROW-ANTLER, among sportsmen, that branch of a deer's horn next his head.

BROW-POST, among builders, the beam that goes across a building.

BROWN, among painters, dyers, &c. a dusky colour with a reddish cast. There are a great variety or degrees of this colour, distinguished by different appellations.

The principal brown colours known among painters are Spanish brown, brown pink, bistre, brown okre, umbre, asphaltum, and Spanish juice, or the extract of liquorice. See each under its proper article. But it must be remembered, that a brown colour of any tinct desired may be procured by a judicious mixture of red, blue, and yellow.

BROWNISTS, in ecclesiastical history, a religious sect that sprung up in England towards the end of the sixteenth century. Their leader was one Robert Brown, a native of Northampton.

They separated from the established church on account of its discipline and form of government. They equally disliked episcopacy and presbyterianism. They condemned the solemn celebration of marriages in churches, maintaining that matrimony being a political contract, the confirmation of it ought to proceed from the civil magistrate. They rejected all forms of prayer, and held that the Lord's prayer was not to be recited as a prayer, being given only as a model, upon which to form our prayers.

BRUMALIA, in antiquity, were festivals of Bacchus, celebrated twice a year, the first on the twelfth of the calends of March, and the other on the eighteenth of the calends of November. They were instituted by Romulus, who during these feasts used to entertain the senate.

BRUNIA, in botany, a genus of pentandrious plants, the flower of which consists of five petals, with slender unguis the length of the calyx ; it contains five capillary filaments, surrounding a small germen crowned with a single style, which is succeeded by a single hairy seed.

BRUNSELSIA, in botany, a pentandrious plant, which rises with a woody stem to the height of eight or ten feet, sending out many side branches, which are covered with a rough bark : these are furnished with oblong, oval, entire leaves. At the extremity of the branches the flowers come out, generally three or four together ; these are monopetalous and funnel-shaped, with a long tube spreading open at the top, and divided into five segments. The fruit is a globose unilocular berry, containing a great number of roundish seeds, placed close to the integument of the berry.

This plant grows naturally in most of the West-Indian islands, where it is called the Trumpet-flower. It is propagated from seeds, but, being tender, requires a hot-house in this climate.

BRUTE, an animal without the use of reason, or that acts by mere instinct, in which sense it implies much the same with beast, and comprehends all animals except the human species.

BRYONIA, bryony, in botany, a perennial plant, the stalks of which are long and slender, a little hairy, and climbing with tendrils like a vine. The leaves are angular, palmated, rough, and callous on both sides ; these are placed alternately on the stalks. The flowers proceed from the hollows where the leaves join to the stalk, and consist each of a single campaniform petal, divided into five roundish sections, of a whitish green colour, marked with veins. Some of these flowers are male, which contain five stamina ; the others are female, and have a deciduous empalement. These contain an embryo, which turns into a spherical berry of the size of a pea ; it is at first green, then turns red, and is full of a nauseous juice, and contains a few oval seeds. The root of this plant is fleshy, and grows

grows to a large size; these have been formerly, by impostors, brought into the resemblance of the human form, and carried about the country, and shewn for mandrakes. The method these people practised, was, to find a young thriving bryony plant; then they opened the earth all round the root, being careful not to disturb the lower fibres. Being prepared with a mould such as is used for casting plaster figures, they fixed the mould close to the root, fastening it with wire, to keep it in its proper situation; then they filled the earth about the root, and left it to grow to the shape of the mould, which in one summer it will do; so that if this be done in March, by September it will have the shape required.

The juice of bryony-root is so sharp as to eat into the skin; however, when they are dry, they lose a great part of their acrimony. It is a strong cathartic, and powerfully dissolves viscid humours, and carries them off by stool, and sometimes by vomiting. It has been used in madness, and some kinds of dropsies with success, as well as in asthma, hysteric complaints, and even in palsies and epilepsies: the dried root, reduced to powder, is given from a scruple to a drachm; but the extract made by water is much the best and safest, because it works in a milder manner, and the dose is from half a drachm to a drachm. Externally, it is a powerful resolvent, and has been recommended against pains in the side; and some will have it almost infallible in arthritic pains and tumours, ordered in a cataplasm. The fresh root being bruised, and laid to the small of the back, has promoted urine, and cured the dropsy; for the hyp-gout it should be bruised, mixed with linseed-oil, and laid warm to the part afflicted. Bryony grows wild under hedges, and climbs upon the bushes, &c. In many parts of England it may be cultivated in gardens, by sowing the seeds in the spring of the year, in a dry, poor soil, where they will, in two years time, grow to be large roots.

Black BRYONY, in botany. See the article *TAMUS*.

Peruvian BRYONY. See the article *JALAP*. *BRYUM*, in botany, a genus of mosses, consisting of a stalk furnished with leaves, which arise immediately from the root: on this stalk stands a separate pedicle, with a conic capsule on its top, covered with a smooth operculum, and containing a fine powder.

BUBALUS, the buffalo. See *BUFFALO*.

BUBBLE, in philosophy, a small drop, or vesicle of any fluid filled with air, and either formed on the surface of the fluid, as in rain, &c. or in its substance, by an internal motion of its component particles.

Bubbles are dilatable and compressible; that is, they take up more or less space, as the included air is more or less heated, or more or less pressed ex-

ternally; because the included air acts equally in every direction. Their coat is formed of minute particles of the fluid, retained by the attraction between those particles.

BUBBLE, in commerce, a cant term given to a kind of projects for raising money on imaginary foundations, much practised in France and England in the years 1719, 1720, 1721.

BUBO, or *BUBOE*, in surgery, a tumour which arises, with inflammation, only in certain or particular parts to which they are proper, as in the arm-pits and in the groin. See the article *TUMOUR*.

The division of a bubo is generally two-fold, the benign and the malignant: a bubo is said to be benign, when it arises spontaneously, without any preceding contagious and pestilential disease, as they frequently do in infants: those are also of this kind which come after benign fevers, being a critical discharge of the disease, and therefore commonly termed pestilential or venereal buboes.

With regard to the causes of benign buboes, they take their rise from an inspissation and obstruction of the blood; so that they differ from other inflammations, only in the particular part where they are seated.

In buboes which are unaccompanied with any other disease, the frequent taking of some cathartic medicine, with an addition of mercurius dulcis, is found to be of great service; other medicines which attenuate the blood, should be also used. When the inflammation is so gentle, as to give hopes of dispersion, it may be proper to apply discutient plasters externally, as *emplastr. diachyl. simplex*, *de spermate ceti*, *de galbano*, &c.

But if the inflammation proves more violent, the pains more intense, and the discutient plasters avail nothing, it will be proper to bring it to suppuration, by the application of *emp. diachylon*, *cum gummis*, or something as effectual. If violent pains also affect the patient, the frequent application of digetting cataplasms warm to the part, will not only mitigate the pain, but also greatly promote a dispersion, or else a digestion and maturation.

Pestilential BUBOES are distinguishable from other tumours, by their happening at a time, and in conjunction with the plague, and from their being accompanied, in the patient, with the symptoms proper to that distemper: these tumours are sometimes joined with carbuncles.

It is not without reason affirmed by some of the more learned and modern physicians, that almost the whole business of curing the plague consisted in carefully promoting the eruption of buboes. The patient, upon the first appearance of the tumours, should keep the house, or rather keep in a warm bed, to be more secure from the air.

Venereal BUBO, a tumour with pain and inflammation,

matation, arising in the groin or arm-pits, after contact with an impure woman who is afflicted with the venereal disease. The most certain signs of buboes being venereal are, the patient's having to do with these women, and from their being, and having been, accompanied with gonorrhæas, chancre, or other symptoms of the venereal disease. With regard to the cure, there are many physicians who hold, that the dispersion of venereal buboes are equally improper as in the pestilential; they therefore judge it necessary to abstain entirely from bleeding, purging, and to forward the tumour to suppuration as fast as possible: however, others are for taking cathartic and mercurial medicines, together with a decoction of the woods, and other purifiers of the blood. The dispersion is to be effected with large doses of mercurius dulcis, as is usual in carrying off gonorrhæas.

Externally to the tumour should be applied some discutient plasters, as those in the pestilential tumours: the patient should keep a regular diet and course of life, and should abstain from strong liquors.

The suppuration is to be promoted much in the same manner as mentioned in the benign and pestilential tumour.

The internal medicines should be a decoction of the woods, two or three times a day, from eight to twelve ounces at a time, with thirty or forty drops of essent. lignor. pimpinellæ, albæ fumarizæ, &c. It is to be opened as the pestilential bubo.

BUBON, Macedonian parsley, in botany, a genus of umbelliferous plants. The common sort has a long, thick, white, wrinkled woody root, which sends forth a stalk to the height of a foot and a half: this is thick, hairy, and branched. The leaves resemble those of garden-parsley, but are more large, of a bright pale-green colour, and serrated on their edges. The flowers grow on the extremities of the branches in umbels; these are whitish, and are each composed of five lanceolated inflexed petals, with the same number of filaments, topped with simple antheræ. The germen, which is situated below the flower, supporting two bristly styles which are persistent, becomes afterwards an oval, striated, hairy fruit, separable into two parts, each containing an oval, aromatic seed, plane on one side, and on the other convex, striated, and hairy.

This plant grows wild in Macedonia, and was greatly valued by the ancients. It is here cultivated in gardens, and propagated by sowing the seeds in light sandy earth in the month of April, and should be kept well watered in dry weather: being somewhat tender, it should be sheltered in winter in this climate. The seeds only are in use, and it has the same virtues as those of the common parsley, but stronger, and is one of the ingredients in Venice-treacle. Botanists enumerated three

other species, two of which are natives of Africa, and the other grows naturally in Sicily.

BUBONOCELE, or **HERNIA INGUINALIS**, in surgery, a tumour in the inguen, formed by a prolapsus of the intestines, omentum, or both, through the processes of the peritonæum, and rings of the abdominal muscles.

The bubonocèle may arise from two causes, viz. a relaxation of the peritonæum and rings of the abdominal muscles, or some violent contraction and pressure of the abdominal muscles upon the intestines, as in jumping, lifting of great weights, coughing, hollowing, blowing a trumpet, riding on horseback, a fall, &c.

When this disorder is formed insensibly, and by degrees, it is attended with but few and slight symptoms: when it arises from violent colds, exercises, eating too plentifully of gross and flatulent food, which will exasperate the disorder, the consequence will be violent pain and inflammation, sickness, vomiting, and the iliac passion. It may be farther discovered from the tumour occasioned thereby in the groin, which proceeds up to the ring of the abdominal muscles; and when the intestine is not incarcerated, but returnable into the abdomen, the tumour subsides upon lying down. When the bubonocèle is incarcerated, so that the parts forming the tumour are not returnable into the abdomen, it usually appears with a greater resistance to the touch, redness, and inflammation.

These ruptures are often attended with danger, especially the incarcerated ones, in which, if the intestine be not timely returned, but the stricture continues two or three days, red and livid spots appear upon the tumour, which denote a sphacelus or mortification; and if an universal cold sweat seizes the patient, he has generally but a few hours to live. When the omentum alone falls down, there is less danger than when it is accompanied with the intestines.

When the intestine is returnable, the patient should be laid on his back, with his thigh a little bent, to relax the integuments; then the tumour is to be gently pressed, or returned with the hands and fingers, after which a plaster and compressure are to be applied to the part affected, and retained with a proper truss, and a girdle or bandage, without taking them off for several months, or longer, as there is occasion. See the article **TRUSS**.

When the intestine is not returnable, then the operation of incision becomes absolutely necessary, in order to dilate the parts. However, the surgeon may first try the repeated use of cataplasms, ointments, and laxative clysters, after bleeding; whereby the stricture is sometimes removed, and the intestine may be returned by the finger, without much difficulty.

BUCARDIA, or **BUCARDITÆ**, in natural history; a kind of figured stones, formed in the cavi-

ries of the larger cockles, and thence necessarily resembling, in some measure, a heart at cards.

BUCCAL, *Buccalis*, something belonging to the cheeks: thus the buccal glands are those dispersed over the inner side of the cheeks.

BUCCANEERS, those who dry and smoke flesh or fish, after the manner of the Americans.

BUCCANEERS also signify those famous adventurers of all the nations in Europe, who formerly joined together to make war against the Spaniards of America, cruizing about in privateers, and taking all the vessels and small craft they could meet with.

BUCCINA, an ancient musical and military instrument. It is usually taken for a kind of a trumpet, which opinion is confirmed by Festus, by this defining it a crooked horn, played on like a trumpet.

BUCCINATOR, in anatomy, a muscle on each side of the face, common to the lips and cheeks. The origin of the buccinator is partly from the anterior and lower part of the coronoide process of the lower jaw, and partly about the roots of the posterior dentes molares of both jaws. Its progress, as the head is erect, is nearly horizontal; its termination is at the angle of the lips. Its uses are to bring the food into the way of the teeth; and the salival duct of Steno perforates it in the middle.

BUCHNERA, in botany, a genus of plants, whose flower consists of a monophyllous calyx, divided into five parts, which is persistent: the corolla is monopetalous, with five equal and obversely cordated segments at its edge, containing four short filaments, topped with oblong antheræ: the fruit is an ovato-oblong capsule, with two cells divided at the top, containing numerous angulated seeds.

BUCCIDA, in botany, a genus of decandrious plants, whose flower is apetalous; the calyx is monophyllous and campanulated, cut into five segments, and persistent; the fruit is a dry ovated berry, with one cell, containing an egg-shaped single seed.

BUCK, among sportsmen, in his first year, is called a fawn; the second, a pricket; the third, a forel; the fourth, a fore; the fifth, a buck of the first head; and the sixth, a great buck. This beast is common in most countries, being corpulent as a hart, but in size resembling more a roe, except in colour; the males have horns, which they lose yearly; the females none at all. As for the colour, it is very different; however, they are mostly branded and sandy, with a black list all along the back. Their flesh is excellent nourishment.

BUCK-BEAN, in botany; see the article MENTHES.

BUCK-THORN, *Rhamnus*, in botany, a shrub which grows naturally in the hedges in divers parts

of England. The root is long, hard, and woody, from which arises a strong woody stalk, to the height of twelve or fourteen feet, sending out many irregular branches, which are armed with thorns. The young shoots have a smooth grayish brown bark, but the older branches have a darker and rougher bark. The leaves stand upon long slender pedicles, and are of a yellowish green; about the size of those of the sloe-tree; these are slightly serrated on their edges, and have a pretty strong midrib, with several veins proceeding from it, which diverge toward the sides, but meet again near the point. The flowers are small, of a greenish or yellowish colour, and come out in bunches from the sides of the branches. Some plants produce male-flowers, and others female. The female-flowers consist of a funnel-shaped petal, cut into four parts at the top; these are succeeded by pulpy berries of a roundish form, green at first, and black when ripe, yielding a bitter greenish black juice, and inclosing four hard seeds.

This plant flowers in June, and the berries are ripe toward the end of September. From the juice of these berries a water-colour is made, called by painters sap-green, which is done by pressing it out when ripe, and then evaporating it to a consistence over a gentle fire, adding to it a little roach-alum, dissolved in water. To give it a higher and more beautiful colour, it must be continued over the fire, till it comes to the consistence of honey; then put in bladders, and hung up in a chimney, or any other hot place, till it becomes hard. When these berries are gathered in harvest time, and steeped in alum-water, they will yield a yellow or saffron-coloured juice. In medicine, these berries prove a strong cathartic: a syrup of them is the only preparation now in use, and is reckoned a good medicine to purge watery humours, and against the dropsy, jaundice, itch, and all manner of eruptions of the skin; a dram, or a dram and a half of the ripe berries is a dose for removing the palsy, gout, and rheumatism. Of late years these berries have been mixed by the people who gather them, with berries of other plants and other virtues, such as those of the frangula, cornus femina, &c. so that when the syrup is made by persons who have not skill enough to distinguish the berries, it is often so very bad, that two ounces of the syrup from one shop, will not purge so well as one from another, which has brought this medicine into disrepute with many persons: but the cheat may easily be detected by opening them, and observing the number of seeds in each; for these contain four seeds, the frangula two, and the cornus femina but one; also by rubbing the juice on white paper, which will stain it of a green colour.

BUCK-WHEAT, the English name of the fagopyrum of authors; it is cultivated in many parts of England, and is a great improvement to dry barren lands.

lands. The best season for sowing the seed is in May: one bushel will sow an acre. The ground should be ploughed and dressed in the same manner as for barley; and, if the soil is not very lean, it will yield a very great increase, as fifty or sixty bushels upon an acre, and is excellent food for hogs, poultry, &c. The flour of it is very white, and makes a very good sort of pancake, if mixed with a little wheat flour. The straw is good fodder for cattle; and the grain, given to horses among their oats, will make them thrive; but it must be broken in a mill; otherwise it is apt to pass through the cattle whole.

It is commonly late in the season before it is ripe; but there is no great danger of the seed's failing, nor of suffering by wet after it is mown: it must lie several days to dry, that the stalks, which are hard, may wither before it is housed.

Buck-wheat is sometimes sown very thick, and suffered to grow until it is near flowering, and is then ploughed in, which makes a very good lay for wheat or rye: but some people esteem it the better way to feed cattle with it, especially milch-cows, which they say will cause them to give a great deal of milk, and make both the butter and cheese very good. This will also afford food for cattle in the driest time, when all other grass is burned up.

BUCKING of Cloth, among bleachers, the first operation or step towards whitening of cloth. See the article **BLEACHING**.

BUCKLE, a well known utensil, made of divers sorts of metals, as gold, silver, steel, brass, &c.

BUCKLER, a piece of defensive armour used by the ancients, and worn on the left arm.

Votive **BUCKLERS**, those consecrated to the gods, and hung up in their temples as an offering to the gods.

BUCKRAM, in commerce, a sort of coarse cloth made of hemp, gummed, calendered, and dyed of several colours.

BUCOLIC, in ancient poetry, a kind of rural poem, relating to shepherds and rural affairs. See **PASTORAL**.

The word is formed from the Greek, *βουκολος*, an herdsman.

BUD, among gardeners, implies that part of a seed which first begins to sprout, or rather the leaves which first appear.

BUD is also used to signify the sprout from whence the branch arises.

BUDDLE, in mineralogy, a name given by the English dressers of the ores of metals to a sort of frame made to receive the ore after its first separation from its grossest foulness.

The ore is first beaten to powder in wooden troughs, thro' which there runs a continual stream of water, which carries off such of it as is fine enough to pass a grating, which is placed at one

end of the trough; this falls into a long square receiver of wood, called the launder: the heaviest and purest of the ore falling at the head of the launder, is taken out separately, and requires little more care or trouble; but the other parts, which spread over the middle and lower end of the launder, is thrown into the buddle, which is a long square frame of boards, about four feet deep, six long, and three wide. In this there stands a man bare-footed, with a trampling shovel in his hand, to cast up the ore about an inch thick upon a square board placed before him as high as his middle; this is termed the buddle-head; and the man dexterously, with one edge of his shovel, cuts and divides it longways, in respect of himself, about half an inch asunder, in these little cuts; the water, coming gently from an edge of an upper plain board, carries away the filth and lighter parts of the prepared ore first, and then the metalline part immediately after, all falling down into the buddle, where, with his bare feet, he strokes it and smooths it, that the water and other heterogeneous matter may the sooner pass off from it.

When the buddle by this means grows full, the ore is taken out; that at the head part, being the finest and purest, is taken out separate from the rest, as from the launder. The rest is again trampled in the same buddle; but the head, or as it is called, the forehead of this buddle, and of the launder, are mixed together, and carried to another buddle, and trampled as at first. The forehead of this last buddle, that is, that part of the ore which has fallen at the head, is carried to what they call a drawing buddle, whose difference from the rest is only this, it has no tyne, but only a plain sloping board on which it is once more washed with the trampling shovel. Tin ore, when it is taken from this, is called black-tin; and this is found to be completely ready for the blowing-house. *Philos. Trans. N° 69.*

BUILDING-DISH, a small, shallow vessel for washing ores by the hand.

BUDGE-BARRELS, among engineers, small barrels well hooped, with only one head; on the other end is nailed a piece of leather, to draw together upon strings like a purse. Their use is for carrying powder along with a gun or mortar, being less dangerous, and carried with more ease than whole barrels. They are likewise used on a battery of mortars, for holding meal powder.

BUFF, in commerce, a sort of leather prepared from the skin of the buffalo, and dressed with oil after the manner of shammy. See **SHAMMY**.

BUFFALO, *Bubalus*, in zoology, an animal of the ox kind, with very large, crooked, and repunated horns.

It is equal to our largest oxen in size: the head is very large, the forehead remarkably broad, and the

the aspect very fierce and terrible. The eyes are large and prominent, the ears long and patulous, the horns very thick but sharp at the point: the neck is thick, and remarkably short; the flesh hangs very loose under the throat: the body is more bulky in proportion than our bull, and the legs are thicker, but about equal in length. The colour is usually a blackish grey; but in this particular there are great varieties.

The buffalo is a native of the East, but has been introduced into Italy, and some other parts of Europe; where it is kept as a beast of burden and draught.

BUFFET, a small apartment separated from the rest of the room by slender wooden columns, glass doors, &c. for the disposing china, glass, plate, &c.

BUFOON, a droll, or mimic, who diverts the public by his pleasantries and follies.

BUFO, the toad, in zoology. See **TOAD**.

BUFONITÆ, in natural history, a kind of extraneous fossils, otherwise called lycodontes, or wolf's teeth. See **LYCODONTES**.

BUGLE, in botany. See the article **BUGULA**.

BUGLOSS, *Buglossum*, in botany, a plant which sends forth stalks about a foot and a half high, which are round and beset with stiff hairs; the leaves are oblong, rough, narrow, and of a bluish green colour, placed alternately on the extremities of the branches; the flowers which come out from the wings of the leaves, and are collected in small heads, of a fine blue colour, each is monopetalous and funnel-shaped, in which are inserted five short filaments, topped with oblong antheræ; it contains four germina, which afterward becomes as many oblong blunt seeds, enveloped in the calyx, and the whole plant has much the appearance of borage. The flowers are in the number of those that are said to be cordial, and are proper to restrain the heat of blood; these may be used in the manner of tea.

This plant is propagated by sowing its seeds either in spring or autumn in light sandy earth, and afterward planted at the distance of two feet from each other in beds; they flower in June, and the seed is ripe in August.

Viper's **BUGLOSS**. See **ECHIU**.

BUGULA, bugle, in botany, a genus of plants, producing didynamious flowers; the common foot which grows naturally in woods and shady moist places in divers parts of England, has a slender fibrous white root, with roundish soft sinuated leaves of a darkish green; it hath two kinds of stalks, one of which creep on the ground and takes root at the joints, while the other arise upright and quadrangular, with hair on the two opposite sides, alternately from joint to joint; the flowers are produced in loose spikes, and are monopetalous and ringent; the upper lip is small, upright and bifid, and the under one large and trifid; the filaments are, two

short and two long, terminated with double antheræ; the calx is monophyllous and persistent, divided into five parts, from whence the pistil arises, and is fixed to the hinder part of the flower; this is attended with four embryoes, which turn to as many seeds, which are inclosed in the calyx.

This plant is greatly esteemed as a vulnerary herb, and is used both internally and externally; it enters as an ingredient into the vulnerary decoctions, and recommended externally, applied to ulcers, and is said to be good in the bloody-flux, and all sorts of hæmorrhages.

This plant is also called *consolida media*, or middle consound, and with the other species of this genus (which are natives of foreign countries) is called by Linnæus, *adjuga*.

BUILDING, a fabric erected by art, either for devotion, magnificence, or conveniency.

BUILDING is also used to signify the art of constructing and raising an edifice; in which sense it comprehends the expences, as well as the invention and execution of the design.

Three things are chiefly necessary to be considered in the art of building, namely, conveniency, firmness, and pleasure: and these Sir Henry Wotton considers under two heads, the situation, and the work.

As to the situation, either that of the whole is to be considered, or that of its parts. In the first, regard must be had to the quality, temperature, and salubrity of the air; to the quality of the soil; to the conveniency of water, fuel, carriage, &c. and to the agreeableness of the prospect.

As to the situation of the parts, the chief rooms, studies, and libraries, should lie towards the East; those offices which require heat, as kitchens, brew-houses, bake-houses, and distillatories, towards the South; those that require a cool, fresh air, as cellars, pantries, and granaries, to the North; as also galleries for paintings, musæums, &c. which require a steady light.

The ancient Greeks and Romans generally situated the fronts of their houses towards the South; but the modern Italians vary very much from this rule. And indeed it is absolutely necessary to have regard to the country, each being obliged to provide against its own inconveniencies.

The situation being fixed on, the next thing to be considered is the work itself, under which come first the principal parts, and next the accessories or ornaments. To the principal parts belong the materials, and the form or disposition.

As for the materials they are either stone, brick, mortar, &c. or wood, as fir, cypress; cedar for pillars for upright uses; oak for summers, beams, and cross-work, or for joining and connection.

As to the form and disposition of a building, it is either simple or mixed.

The simple forms are either circular or angular.

The circular form is very commodious, and the most capacious of any, strong, durable, and very beautiful; but is the most chargeable of all others, and much room is lost by the bending of the walls, when it comes to be divided into apartments; besides an ill distribution of the light, unless it be from the center of the roof. For these reasons, the ancients employed this form only in their temples and amphitheatres, which had no need of partitions.

As for angular forms, building neither loves many nor few angles. The triangle is condemned above all others, as wanting both capaciousness and firmness, as also on account of its not being resolvable, in the internal partitions, into any other figure than its own. Buildings with five, six, or more angles, are more fit for fortifications than civil edifices. The rectangle, therefore, is generally chosen, as being a medium between the triangle and the pentagon, &c. But then authors are in dispute, whether the rectangle should be an exact square, or an oblong; and Sir H. Wotton prefers the oblong, provided the length exceeds not the breadth by more than one-third. As to mixed forms, partly circular, and partly angular, a judgment may be made of them, from what has been already said of simple ones. Let the builder, however, remember not to lose sight of uniformity, while he is in pursuit of variety; for these two may be very well reconciled, as may be observed in our bodies, which are uniform in the whole configuration; and yet some of the members are round, others flat; some prominent, and others indented, or retired.

Some observe, that in building houses long, the use of some rooms will be lost; as they will take up more for entries and passages, and will require too much for doors; and if the building be a geometrical square, the middle rooms will want light, in case the house be pretty large; and therefore they recommend the form of the letter H, a form, say they, in which the building stands firmer against the weather, and in which the offices may be remote from the parlour and rooms of entertainment, and yet in the same house.

This figure may serve very well for a country gentleman's house.

The principal parts of a building are comprized, by Baptista Alberti, under five heads, viz. the foundation, the walls, the apertures, the partitions, and the covering; see each under its proper article, as FOUNDATION, &c.

The accessories or ornaments of a building are fetched from sculpture and painting. In the first, care ought to be taken that there be not too much of it, especially at the entrance; and that both in fine and coarse pieces of sculpture, and likewise in placing figures aloft, the rules of perspective be strictly observed.

In painting, the chief things to be regarded are, that the best pieces be placed in the best lights; and that they be suited to the intention of the rooms they are used in.

If we compare the modern with the old way of building in England, we cannot but wonder at the genius of those times. Our fore-fathers were wont to dwell in houses, most of them with a blind stair-case, low ceilings, and dark windows; the rooms built at random, without any contrivance, and often with steps from one to another: whereas the genius of our times requires light stair-cases, fine sash-windows, and lofty ceilings, with conveniences far superior to those that houses in ancient days afforded upon an equal quantity of ground.

Ship-BUILDING, the art of designing the figure, forming the several limbs, and constructing the body of a ship or vessel. See NAVAL ARCHITECTURE.

In the article referred to, and to which this may be properly esteemed a conclusion, the reader will find a general account of the rise and progress of *Ship-BUILDING*, together with a comparative view of the art, as it has appeared amongst the ancients and moderns: we likewise at that time ventured to censure the evident impropriety of pretending to establish general rules of proportion, a maxim so often absurdly adopted amongst many of our modern *Ship-BUILDERS*, who for want of a native genius and taste, and a sufficient knowledge of the nature of physics, mathematics, solids, and fluids, were necessitated to pursue the servile mechanical methods handed down to them by their laborious preceptors: it shall be our present endeavour to speak more particularly of the principal members that compose this complicated machine; in which we shall decline as much as possible to distract our reader's attention, by drawing him into a labyrinth of technical terms, from which we can neither extricate him nor ourselves.

But it will be necessary on this occasion to say something of the different parts used in fabricating the ships of the ancients, previous to an explanation of modern ship-building.

The ignorance of the principal parts of their shipping has occasioned many mistakes and much confusion in those who have conversed with authors of antiquity. Herein we shall chiefly follow Scheffer, who hath so copiously treated this subject, and with such industry and learning, collected whatever is necessary to illustrate it, that very little room is left for enlargement by those who incline to pursue this investigation.

The chief parts then, of which ships formerly consisted, were three, viz. the *belly*, the *prows*, and the *stern*: these were again composed of other smaller parts, which shall briefly be described in their order.

1. In the belly or middle part of the ship there

was *τρόπις*, *carina*, or the keel, which was composed of wood : it was placed at the bottom of the ship, being designed to cut and glide through the waves, and therefore was not broad, but narrow and sharp ; whence it may be perceived that not all ships, but only the *μακραί*, which ships of war were called, whose bellies were straight, and of a small circumference, were provided with keels, the rest having usually flat-bottoms. Round the outside of the keel were fixed pieces of wood to prevent it from being damaged, when the ship was first launched into the water, or afterwards struck on any rocks ; these were called *χελεύματα*, in Latin *cunci*.

Next to the keel was *φάλλις*, the pump-well or well-room, within which was contained the *ἀντλία*, or pump, through which water was conveyed out of the ship.

After this, there was *δευτέρα τρόπις*, or the second keel, somewhat resembling what is now called the keelson ; it was placed beneath the pump, and called *λέσιον*, *χαλκῆν*, *κλειτοπόδιον* : by some it is falsely supposed to be the same with *φάλλις*.

Above the pump was an hollow place, called by Herodotus *πόλις τῆς νῆος*, by Pollux *κύτος* and *γαστέρα*, because large and capacious, after the form of a belly, by the Latins *testudo*. This was formed by crooked ribs, with which it was surrounded, which were pieces of wood rising from the keel upwards, and called by Helychius *νομῆς*, and by others *ἐνδομία*, the belly of the ship being contained within them, in Latin *coster*, and in English timbers : upon these were placed certain planks, which Aristophanes calls *ἐντερωνίας*, or *ἐντερωνία*.

Hence proceed we to the *πλευραί*, *lateræ*, or sides of the ship, which encompassed all the former parts on both hands ; these were composed of large rafters extended from prow to stern, and called *ζωτηρές*, and *ζωμιάματα*, because by them the whole fabric was begirt or surrounded.

In both these sides the rowers had their places, called *τοῖχοι*, and *ἑδάλια*, in Latin *fori* and *transfra*, placed above one another : the lowest was called *θάλαμος* and those that laboured therein *θαλάμιοι* ; the middle *ζυγάς*, and the men *ζύγιοι* ; the uppermost *θράνοι*, whence the rowers were termed *θρανίται*. In these apartments were spaces through which the rowers put their oars ; these were sometimes one continued vacuity from one end to the other, called *τράση*, but more usually distinct holes, each of which was designed for a single oar ; these were filled *τέμματα*, *τροπήματα*, as also *ὀφθαλμοί*, because not unlike the eyes of living creatures : all of them were by a more general name termed *ἔγκωπα*, from containing the oars ; but *ἔγκωπι* seems to have been another thing, signifying the spaces between the banks of oars on each side, where the passengers seem to have been placed : on the top of all there was a passage or place to walk, called *παρόδος*,

and *παράβατος*, as joining to the *θράνοι*, or uppermost bank of oars.

2. *Πρόρα*, the prow or fore-deck, whence it is sometimes called *μέτωπον*, and commonly distinguished by other metaphorical titles taken from human faces. In some ships there is mention of two prows, as also two sterns ; such was Danaus's ship adorned by Minerva when he fled from Egypt. It was usual to beautify the prow with gold and various sorts of paint and colours : in the primitive times red was most in use, whence Homer's ships were commonly dignified with the titles of *μυτοπάρηροι*, and *φουικοπάρηροι*, or red-faced : the blue likewise or sky-colour was frequently made use of, as bearing a near resemblance to the colour of the sea, whence we find ships called by Homer *κυανόπρωροι*, by Aristophanes *κυανέμβολοι*. Several other colours were also made use of ; nor were they barely varnished over with them, but very often annealed by wax melted in the fire, so as neither the sun, winds, nor water, were able to deface them. The art of doing this, was called from the wax *κηρογραφία*, from the fire *ἐκκαυτική*, which is described by Vitruvius, and mentioned in Ovid.

— *Picta coloribus uestis*
Ceruleam matrem concava puppis habet.

The painted ship with melted wax anneal'd
Had *Tethys* for its deity. —

In these colours the various forms of gods, animals, plants, &c. were usually drawn, which were likewise often added as ornaments to other parts of the ships, as plainly appears from the ancient monuments presented to the world by Baysius.

The sides of the prow were termed *πτερά*, or wings, and *πάρεια*, according to Scheffer, or rather *παρειαί* ; for since the prow is commonly compared to an human face, it will naturally follow that the sides should be called cheeks ; these are now called bows by our mariners.

3. *Πρύμν*, the hind-deck or poop, sometimes called *ἔρα*, the tail, because the hindmost part of the ship : it was of a figure more inclining to round than the prow, the extremity of which was sharp, that it might cut the waters ; it was also built higher than the prow, and was the place where the pilot sat to steer, the outer-bending part of it was called *ἐπιστήριον*, answering to our term, quarter.

They had various ornaments of sculpture on the prow ; as helmets, animals, triumphal wreaths, &c. the stern was more particularly adorned with wings, shields, &c. Sometimes a little mast was erected whereon to hang ribbands of divers colours, which served instead of a flag to distinguish the ship, and a weather-cock to signify the part from whence the wind blew. See COLOURS, FLAG, SIGNAL.

On the extremity of the prow was placed a round piece

piece of wood, called the *σπυρίς*, from its bending; and sometimes *ὀφθαλμός*, the eye of the ship, because fixed in the fore-deck; on this was inscribed the name of the ship, which was usually taken from the figure painted on the flag. Hence comes the frequent mention of ships called *Pegasi*, *Scyæ*, *Bulls*, *Rams*, *Tigers*, &c. which the poets took the liberty to represent as living creatures that transported their riders from one country to another. See the article SEA-FIGHT.

The whole fabric being compleated, it was fortified with pitch, and sometimes a mixture of rosin, to secure the wood from the waters; whence it comes that Homer's ships are every where mentioned with the epithet of *μέλαινα*, or black. The first that made use of pitch were the inhabitants of Phæacia, since called Corsica: sometimes wax was employed in the same use, whence Ovid,

Caerula ceratas accipit unda rates.

The azure waves receive the waxy ships.

After all, the ship being bedecked with garlands and flowers, the mariners also adorned with crowns, she was launched into the sea with loud acclamations and other expressions of joy; and being purified by a priest with a lighted torch, an egg and brimstone, or after some other manner, was consecrated to the god whose image she bore.

With regard to modern Ship-BUILDING, it is necessary to observe here, that the art is so complicated, extensive and various, comprehending such a diversity of structures, that to treat the subject at large with perspicuity and precision would fill a large volume of itself, and therefore would greatly exceed our bounds; and being thus necessitated to contract our description, we cannot treat particularly of all the pieces that compose a ship. It seems necessary, however, to say something of the principal pieces: we have therefore laid down each piece separately, Plate XXIV, by which means the length of the scarphs are described, and the manner in which they are to be joined together.

EXPLANATION OF PLATE XXIV.

A. The keel, in four pieces, to be firmly bolted together and clinched.

I. The fore-foot, one end of which is scarfed to the fore-end of the keel, of which it is a part, and the other end makes a part of the stem, to which it is scarfed.

u u. Two pieces of dead-wood, one afore and the other abaft, fayed upon the keel.

Note, The term *afore* arrived too late for the press in this Dictionary: it means further, forward, or nearer the stern, and is the opposite term to *abaft*; which see.

CC. The stem in two pieces to be scarfed together: it is the circular piece of timber where both the sides of the ship unite forward.

EE. The apron, in two pieces, to be scarfed together, and fayed on the inside of the stem, to support the scarf of the stem; for which purpose the scarf of the apron must be clear from that of the stem.

o. The stemson in two pieces, to support the scarf of the apron.

o. The false post, which is fayed to the fore-part of the stern-post. Faying is fitting two pieces of wood, so as that one may be joined to the back, or inside of the other, so as to lie close.

B. The stern-post: it is tenanted into the keel, to which it is fastened with a knee; and is that straight piece of timber at the after-end of the ship, into which both the sides are united.

D. The back of the post, which is likewise tenanted into the keel, and securely bolted to the stern-post; the design of it is to give sufficient breadth to the post, which seldom can be procured of a sufficient breadth in one piece.

F. The knee which fastens the post to the keel.

N. The wing-transom. It is fayed across the stern-post, and bolted to the head of it: the fashion-pieces are fastened to the end of it; under this and parallel to it is the deck transom.

OO. Two transoms fastened to the stern-post and fashion-pieces, in the same manner as the wing-transom.

P. The transom-knee which fasteneth it to the ship's side.

Q. The fashion-piece, of which there is one on each side: their heels are fastened to the stern-post, at the height of the floor-ribbands, and their heads are fastened to the wing-transom.

T. A floor-timber: it is layed across the keel, to which it is fastened by a bolt through the middle.

TTTTT. 2d, 3d, 4th futtocks and top-timbers. These shew the proper length and scarf of the timbers, in what is called the midship-frame, which is a plane comprehended between the two sides, at their extreme breadth, and the keel to which it is perpendicular; so that if a ship were cut through perpendicular to her length, and at her greatest breadth, the exterior and interior part of both sides from the upper-parts or edges, called the gunnels, down to the keel, would exhibit the midship-frame. The futtocks are to be joined, to complete a frame of timbers.

UU. Riders: these are fayed on the inside of the ship across the keel, and stand in the same manner as the timbers, and consist of floor and futtock riders.

Z. The kelson: this is made of two or three large pieces of timber scarfed together in the same manner as the keel. It is placed over the middle of the

the floor-timbers, and scored about an inch and a half down upon each of them.

R, S. Breast-hooks : these are fayed on the inside across to the stem, and to the bow on each side of it, to which they are fastened with proper bolts. There are generally four or five in the form of an R in the hold, one in the form of S, into which the lower-deck planks are rabbitted ; there is one right under the hawse-holes, and another under the second deck.

X, Y, X. Are thick planks which are fayed to the inside, and stretch fore and aft, or from one end of the ship to the other, to support the scarfing of the timbers.

Z. Are thick planks in the inside called clamps, which sustain the ends of the beams.

15, 15, 15, 15, 15. Are the wales : they are planks broader and thicker than the rest, which are fastened to the outside of the ship on a line with the decks : with regard to the planks reaching from the wale upwards to the top of the side, and downwards to the keel, the reader is referred to the section of one half of the midship frame, as laid down in the plate.

$d_1, d_2, d_3, d_4, d_5, d_6$. Are kness. These are crooked pieces of timber consisting of two arms, which form an angle sometimes acute and sometimes obtuse or rectangular : their use is to fasten any two pieces together ; as the beams to the ship's side, &c.

19. The rudder : this is joined to the stern-post by the rudder-irons, upon which it turns round in the googings, which are fastened upon the stern-post for that purpose. There is a mortise cut through the head of it, into which a long bar is fitted, called the tiller, by which the rudder is turned from one side to the other, and both parts together, are called the helm.

23. The cat-heads. These are two large square pieces of timber, one on each side of the bowsprit : they project from the bow over the side, in order to keep the anchor clear of the ship, which is drawn up by a rope called the cat-fall, which passes through certain pulleys, called sheaves, in the outer-end of the cat-head : their inner-ends are fastened upon the fore-castle.

m, m_1, i, i_1 . Are the several pieces which compose the knee of the head, called by seamen the cut-water ; the lower-part m is fayed to the stem, the keel of it is scarfed to the head of the fore-foot ; it is fastened to the bows by two knees, called cheeks, and to the stem by a knee called a standard in the form of a K.

a, X, Y . Are beams, or large pieces of timber which support the planks of each deck. See the article BEAMS. The reader will readily discover that the two sides of the midship-frame in the middle of the plate are so disposed, that all the pieces on one side may be seen before they are joined, and on the other after they are fixed in their proper places.

In ships of war the general dimensions are established by the authority of those appointed by the government for that purpose. In the merchants service, the extreme breadth, length of the keel, depth in the hold, and height in the wale, and between decks ; and sometimes the height and breadth of the wing-transom, are agreed on by contract : and from these dimensions the builder is to form a draught suitable to the trade for which she is designed.

The first thing to be done, in order to lay down the design of a ship of war, is to determine the length, which should be either on the lower-gun deck, or at the load-water-line : water-lines are described lengthways on a ship's bottom by the surface of the water in which she swims ; that which determines how much she is under water when laden, is called the load-water-line, which is commonly at, or a little below her extreme length : there must be great care that sufficient room be left between the ports.

The next thing is to establish the breadth by the midship-beam ; although some builders are divided in their opinion, about proportioning this to the length, yet most of them conform to dimensions of ships of the same rate. After these two dimensions are determined, the depth of the hold must be fixed, which in most ships is half the breadth ; but the form of the body should be considered ; for a flat floor will require less hold than a sharp one. The distances between the decks must also be determined.

We may then proceed to fix the length of the keel, which will oblige us to establish the rake of the stem and stern-post : rake is the difference between a ship's lengths at the keel and upper-deck, or the line on which she gradually projects farther out with the stem and stern as the fabric rises. The height of the stem and wing-transom must also be fixed.

After these dimensions are settled, the timbers may be considered which form the sides of the ship. A frame of timbers, which appears to be one continued timber, is composed of one floor-timber, two or three futtocks, and a top-timber on each side : all these being united and secured by cross-bars, form a circular inclosure ; that which incloses the greatest space is called the midship-frame : the curve of this frame is inverted at the lower part, so that the floor-timber will be somewhat hollow in the middle, whereby the ends will form a very obtuse angle ; but this angle decreases, the farther the frames are removed from the midships, in such a manner, that the foremost and aftmost will become very sharp, and form a very acute angle. Floor-timbers of this kind are called crutches.

Builders differ much in determining the station of the midship-frame, some placing it before, and others at the middle of the ship. Those who place

it before alledge, that if a ship is full forward, she will meet with no resistance after she has once opened a column of water, and that the water so displaced will easily unite abaft, and by that means force the ship forward, and have more power on the rudder, the farther it is from the center of gravity; and besides this, comes nearest the form of fishes, which should seem to be the most advantageous for dividing fluids.

When the rising of the midship floor-timber is agreed on, we may then proceed to decide the rising-line of the floor abaft on the stern-post, and afore on the stem.

The height of the lower-deck is the next thing to be considered: it is determined in midships by the depth of the hold; and some builders make it no higher than the stem, but they raise it more than it is in the midships, by as much as the load-water-mark abaft exceeds that afore. As to the height between decks, it is altogether arbitrary, and must be determined by the rate of the ship, and the service she is designed for.

We come now to consider the upper-work, or all that is above water, called the dead work; and here the ship must be narrower; so that all the weight, lying above the load-water-line, will thereby be brought nearer the middle of the ship; by which means she will strain less by working the guns, &c. But though these advantages are gained by narrowing a ship above water, great care must be taken not to narrow her too much, for there must be sufficient room upon the upper-deck for the guns to recoil. The security of the masts should likewise be remembered, which requires sufficient breadth to spread the shrouds, although this may be in some measure supplied by enlarging the breadth of the channels which spread them.

In the article *NAVAL Architecture*, we occasionally mentioned several essential qualities which ought to be united in a ship; and we shall here briefly describe the manner in which this may be executed.

To make a ship carry a good sail. A flat floor-timber, and somewhat long, or the lower-futtock pretty round, a straight upper-futtock, the top-timber to throw the breadth out aloft; at any rate to carry her main breadth as high as the lower-deck. Now if the rigging be well adapted to such a body, and the upper-works lightened as much as possible; so that they all concur to lower the center of gravity, there will be no room to doubt of her carrying a good sail.

To make a ship steer well, and answer the helm quickly. If the fashion-pieces be well formed, the tuck, or spreading-parts under the stern carried pretty high, the midship-frame well forward, a considerable difference in the draught of water abaft more than afore, a great rake forward and none abaft, a snug quarter-deck and fore-castle; all these will

make a ship steer well. A ship which sails well, will certainly steer well.

To make a ship carry her guns well out of the water. A long floor timber, and not of great rising; a very full midship-frame, and low tuck, with light upper-works.

To make a ship go smoothly through the water without pitching hard. A long keel, a long floor, not to rise too high afore and abaft; but the area or space continued in the fore-body, according to the respective weights they are to carry; all these are necessary to make a ship go smoothly through the water.

To make a ship keep a good wind, and drive little to the leeward. A good length by the keel; not too broad, but pretty deep in the hold, which will occasion her to have a short floor-timber, and a great rising.

As such a ship will meet with great resistance in the water going over the broadside, and little when going a-head, she will not fall much to the leeward.

Now some builders imagine it is impossible to make a ship carry her guns well, bear a good sail, and be a prime sailer; because it would require a very full bottom to gain the first two qualities, whereas a sharp ship will answer better for the latter; but when it is considered that a full ship will carry a great deal more sail than a sharp one, a good artist may so form the body, as to have all these three good qualities, and also steer well. After what has been said on this, it certainly cannot be thought impossible to unite all these different qualities in one ship: giving the water a proper curve, ought likewise to be considered, upon which the beauty and stateliness of a ship greatly depend; since it is this which makes a ship look airy and graceful in the water. There is no certain rule for laying them down; this is left entirely to the fancy and taste of the artist, which, as we have more than once observed, is not often of the most delicate degree, or corrected by truth and judgment; witness the barbarous and unnatural mixture of Gothic and Chinese ornaments, "clumsy heroes and fat-headed gods," on the same ship, the monstrous issue of a savage conception and an awkward genius, as deformed and awkward as their own cant-timbers. See the article *CARVED-WORK*, where we shall exhibit a further proof of this.

We refer such readers as wish to be more fully or particularly informed of Ship Building to M. Du Hamel's curious and useful *Elements of Naval Architecture*, to which we acknowledge ourselves greatly indebted for the above description. Mr. Mungo Murray has also published a book on this subject, called a *Treatise on Ship-Building*, &c. which must be of great service to the younger artificers of this profession, as it contains variety of very accurate drawings

drawings of ships. An abridgment of M. Du Hamel's book, referred to above, is also translated, and annexed to Murray's Treatise.

BUL, in the Hebrew chronology, the eighth month of the ecclesiastical, and the second of the civil year; the modern Jews call it Morshivan, and it nearly answers to our month of October.

BULB, or **BULBOUS ROOT**, among gardeners, signifies a root of a roundish form, and commonly furnished with fibres at its base. An uniform bulb, is when it is composed of the same matter throughout, without any lines intervening; a truncated bulb consists of many coats surrounding each other, as in the narcissus, tulip, onion, &c. a squamous bulb consists of many scales laying over each other like the tiles on a house, or the scales of fishes, as the roots of the lilly, martagon, &c.

BULLOCASTANUM, in botany. See **BUNUM**.

BULBOCODIUM, in botany, a genus of plants, producing hexapetalous funnel-shaped flowers. One of the species which grows naturally on the Alps, hath a small bulbous root, covered with a rough hairy skin, from which issues forth a few long narrow leaves; from the middle of these comes forth the flower, which is erect, and stands on the top of the footstalk, which rises about three inches high, and hath four or five narrow leaves placed alternately upon it below the flower. This plant flowers in March, and the seeds are ripe in May. The whole plant has much the appearance of the saffron, or crocus, and is propagated in the same manner.

BULGARIANS, a sect of heretics, who, among other errors, held that men ought to believe no Scripture but the New Testament; that baptism was not necessary to infants; that husbands who conversed with their wives could not be saved; and that an oath was absolutely unlawful.

BULIMY, among physicians, a disease in which the patient is affected with an insatiable desire of eating, and unless indulged, often falls into fainting fits.

BULK-HEADS, in naval architecture, certain partitions built up in different places of a ship, either across or lengthwise, to form and separate the various apartments.

BULL, *Taurus*, in zoology, the male of the ox kind. See the article **BOS**.

BULL, *Taurus*, in astronomy. See the article **TAURUS**.

BULL'S-EYE, in astronomy; see **ALDEBARAN**.

BULL'S-EYE, in the marine, a sort of small pulley in the form of a ring, round whose outer-edge, which is made concave for that purpose, a rope is fitted, and spliced close about it: it is used to pass a rope through when it is required to haul the rope tight above and below, as the bowline-bridle, upon which the bull's-eye slide up and down occasionally:

this is more frequent amongst the Dutch than English.

BULL-FINCH, in ornithology, the English name of the loxia with a black head, and red breast. It is about the size of a common sparrow; and its wings are elegantly variegated with black and red.

BULL-FROG, the largest kind of frog. See **RANA**.

BULL, among ecclesiastical writers, implies a written letter, dispatched by order of the pope, from the Roman chancery, and sealed with lead. It is written on parchment, by which it is distinguished from a brief.

Golden BULL, an edict or imperial constitution, made by the emperor Charles IV. and esteemed as the Magna Charta, or fundamental law of the German empire.

It is dignified with the epithet golden, from its having a golden seal appended to it with cords of red and yellow silk. On one side of this seal the emperor is represented as sitting on his throne, and on the other the capitol of Rome. The original of this edict, which is in Latin, and written on vellum, is preserved at Frankfort.

BULLACE-TREE, in botany, a wild plum growing in hedges in many parts of England. There are two sorts, the black and the white bullace, which are rarely cultivated in gardens: for their general characters, see the article **PRUNUS**, of which they are a species.

BULLET, a leaden or iron ball or shot, where-with fire-arms are charged; they are of various sorts and dimensions. See the article **BALL** and **SHOT**.

It is demonstrated in the Elements of Geometry, that similar solids are to each other, as the cubes of their homologous, or correspondent sides or diameters: bullets are similar solids, and therefore they are to one another as the cubes of their diameters. If we suppose the weight and diameter of a bullet to be known by experiment; for example, if it is found that a bullet of four pounds weight is three inches in diameter, the weight of any bullet may be easily found, if its diameter be given, and the diameter of any bullet, if the weight be given.

Let it be supposed, for instance, that the weight of a bullet of five inches diameter is required; this will be found by the Rule of Three, by saying, As the cube of 3, which is 27, is to the cube of 5, which is 125, so is four pounds to the fourth term, or the weight required; or $27 : 125 :: 4 : \text{the fourth term}$, which will appear to be eighteen pounds and a half, the weight of a bullet of five inches diameter: by the same rule the diameter of bullets may be found, whose weight are given; for the Rule of Three having produced the fourth term, or the cube of the diameter required, the diameter sought will appear, by extracting the cube root from it.

of white lillies, of henbane, &c. with these the part affected should be frequently anointed. The vulgar method of applying the burnt part to a candle, or the fire, and keeping it in that position as long as you can bear it, repeating this process till all sort of heat and pain is removed, is frequently attended with success. The injured part may be fomented with water, as hot as the patient can bear it, till the pain and heat entirely disappear.

When the burn is of the second degree, which is attended with a blister, it seems improper to open the vesicle, or cut the skin already lacerated; but the best method, in this case, is, with all the haste possible, to apply one or other of the medicines prescribed in the first degree, and renewing it very frequently: if the pain continues, lenitive remedies are to be used; here the most eligible medicines are the linseed oil, Myrsich's ointment, unguentum nutritum, &c. With these the part must be often anointed; or they must be spread on linen, and bound to the part affected: as the pain and heat gradually decrease, some plaster, as that of red lead, may be applied, in order to smooth and restore the skin. If this second degree be more intense than ordinary, and affects a great part of the body, it will be necessary forthwith to take away some blood, in proportion to the violence of the burn, even till the patient faints, in order to prevent exulcerations, deformities by seams, and perhaps a gangrene: after which a strong cathartic should be used.

As to the third degree, in which a crust immediately covers the burnt part, it is very difficult, if not absolutely impossible to cure it, without a supuration. When this happens in the face, all diligence should be used to prevent deformity, which may be occasioned by a large cicatrix; therefore, in this case, the use of all plasters and ointments whatsoever is to be avoided: but you cannot be too solicitous in forwarding the casting off of the eschar, or crust, and the evacuation of the matter that is concealed under it; yet it should not be torn away with the knife, nor separated with the hands: the easiest and most successful method is by the use of emollients, such as have been mentioned already, applied warm, and repeated till the hard crusts separate from the live flesh; that part should be dressed two or three times a day, and at each dressing, if you should observe any portion of the crust tending to a separation from the rest, it should be removed with the forceps, and the remaining crust anointed with butter, at the same time never neglecting the use of fomentations. The crust being taken off, the wound must be cleansed and healed, the first of which offices may be executed by any mild digestive ointment, mixed up with mel rosarum: the medicines used for healing are principally unguentum diapompholygos, vel de lithargyrio, &c. but if any portion of the eschar is left under these ointments

and plasters, a danger follows of making a deformed cicatrix, from the constriction of the neighbouring parts, and from the acrimony of the confined sanies. Evacuations by bleeding and purging are always to be preferred, and proper regulations, with regard to diet, must be complied with: the best method of encouraging the renovation of the skin, is by frequently holding the burnt part over the steam that rises from boiling water. But as to the fourth degree, which is always attended with extreme danger, where the burning has penetrated to such a depth as to corrupt and mortify all before it, almost to the very bone, all remedies are vain and useless, and there is no other way of assisting the patient, but by cutting off the affected limb, as is done in a sphacelus.

BURNET, the English name of a plant called *pimpinella* by Linnæus, and *tragofelinum* by Tournefort.

It is a native of this country, and promises very great advantages as a green succulent food for cattle during the winter months; and the judicious Mr. Rocque, on observing that burnet retains its verdure amidst all the inclemencies of that season, resolved to try the effect of giving it a good culture. He has succeeded therein to his utmost wish; and the plant bids fair to be of singular utility, where flocks of sheep are kept, because, as it preserves all its leaves unhurt by frost, the farmer may thereby have a constant stock of green food for his ewes and lambs, at a time when turnips and every other succulent plant may fail him.

In describing this plant, Mr. Miller distinguishes seven different species of it; but only three, or perhaps rather but two, of them seem to be the sorts proper to be cultivated for the food of cattle. These are; 1. The *tragofelinum majus*, *umbella candida*, greater burnet *faxifrage*, with a white umbel. 2. *Tragofelinum alterum majus*, another greater burnet *faxifrage*; and 3. The *tragofelinum minus*, or lesser burnet *faxifrage*. All these are equally hardy plants, and natives of this island: but the largest sorts promise the greatest quantity of fodder, and therefore should, probably, be preferred by the husbandman. A fourth sort, which Mr. Miller mentions by the title of *tragofelinum radice nigra Germanicum*, German burnet *faxifrage* with a black root, will probably answer as well in its native country, Germany, as ours will here: and I therefore recommend the trying of it there; as I do to other countries, the cultivating of their native species of this plant, in full confidence that they will find it answer greatly for the winter green food of their cattle. Experience has proved that all countries are benefited by the introduction of foreign plants, as particularly the lucerne, sainfoin, &c. I therefore take this opportunity of recommending a trial of the German burnet here, and of ours in Germany and elsewhere.

The first of the above-mentioned species of burnet grows naturally in woods, and on the sides of banks near hedges, in several parts of England. The lower leaves of this sort are winged, and composed of three pair of heart-shaped lobes, terminated by an odd one: they are sharply sawed on their edges, and sit close to the mid-rib. The lower lobes, which are the largest, are near two inches long, and one and a half broad at their base, and are of a dark green. The stalks grow more than a foot high, dividing into four or five branches; the lower part of the stalk is garnished with winged leaves, shaped like those at the bottom, but smaller; those upon the branches are short and trifid; and the branches are terminated by small umbels of white flowers, which are composed of smaller umbels or rays. The flowers have five heart-shaped petals, which turn inward, and are succeeded by two narrow, oblong, channelled seeds. It flowers in July, and the seeds ripen in autumn. A variety of this with red flowers is frequently found among the other, and rises from the same seed.

The second sort grows naturally in dry pastures in many parts of this island. The lower leaves of this are composed of four pair of lobes, terminated by an odd one; these are roundish; those on the lower part of the leaf are about half an inch long, and the same in breadth: they are indented on their edges. The stalks rise near a foot high, and send out three or four slender branches, which are garnished with very narrow leaves. The umbels of the flowers of this are smaller than those of the former sort, as are also the flowers and seeds, which blow and ripen about the same time.

The third, or smaller sort of burnet, grows naturally in dry gravelly pastures in several parts of this country. Its lower leaves have five or six pair of lobes terminated by an odd one, and are deeply cut almost to their mid-rib, in form of wings. The stalks are slender, and rise about a foot high, sending out a few branches, which have a narrow trifid leaf placed at each joint, and are terminated by small umbels of white flowers, composed of several rays standing upon pretty long foot-stalks. The flowers of this sort appear, and its seeds ripen, at the same time as those of the former; but they are smaller.

In the meadows about Windsor, half the grass is burnet. Mr. Rocque has experienced, that it will grow in the driest land: for he has planted some of it even in the gravel walks in his garden, where every thing else is burnt up in the summer, but this never withers; one of the qualities of burnet being to continue in sap all the year. It is the opinion of many who have seen the burnet of his raising, that if this plant is generally cultivated, there will never be a scarcity of hay in England, even in the greatest drought.

The land on which it is sown should be in fine

tilth, and free from weeds, especially couch-grass, which is here the most hurtful of all. A drag, that is to say, such a fork as the gardeners clean their asparagus with, is the best instrument for extirpating this weed. The dragging of an acre thus will cost six or seven shillings. If the land is poor, it should be dunged, and laid down very smooth. The seed may be covered with a very light harrow, for it will not bear to be buried very deep, and the ground should then be rolled, that it may be smooth for mowing. It may be sown at any time between April and September.

Ten pounds of burnet-seed may do for an acre of land; but twelve, fourteen, or even sixteen pounds will be better; because, when burnet is thin, the plants grow so large, that the hay made of them is coarse. These will rise in eight or nine days after the sowing. If great numbers of weeds come up with them, it will be less chargeable to let those weeds grow with the burnet, till it is about five or six inches high, than to weed or hoe it. The whole may then be mowed, and gathered clean off; and the quick growth of the burnet afterwards will choke all other weeds. The heart of the burnet being almost within the ground, the scythe cannot hurt it.

If the burnet does not grow equally every where, some plants must be drawn where they are too thick, and planted where they are thinnest: or the vacant spaces may be supplied from the nursery. If the land was not in good order to sow the seeds at a proper season, the burnet may be transplanted at Michaelmas from this nursery, and set at nine or twelve inches distance every way, according to the richness of the soil.

The seed sown in May may be mowed at the latter end of July. That sown in June will yield a pretty good crop, and must be cut but once; and the same of that which is sown in July. The plants produced by the seeds sown in August should be mowed, to destroy the weeds. These mowings may either be given green to horses, or be made into hay. The first spring cutting will purge horses; and Mr. Rocque believes it will also cure the grease: but it is only the first crop that purges.

Burnet should be mowed but once the first year, in order to leave it rank in the winter; and in this case it will be ready to feed in February or March, or to mow again in April.

If natural grass grows among the burnet, it may be harrowed in the same manner as lucerne; for, having a tap-root, the harrow will not hurt it: but it must not be ploughed, lest the roots should be broken in the ground.

When the seeds of this plant are to be saved, it must neither be fed, nor mowed, in the spring. The seed will be ripe about the middle of June, when it must be reaped like wheat, and threshed on a cloth. It should be threshed before it is too dry, because

because it is apt to shed, and it should afterwards be dried perfectly.

Burnet does not lose its leaves in drying; and though the hay made of it be sticky, it will, after threshing, be very agreeable to horses, which are so fond of it, that they never waste any. One acre will produce upwards of three loads of hay, and above forty bushels of seeds. Horses are fonder of this feed, than they are of oats: and Mr. Rocque is of opinion, that it is a more proper food for those who do not labour hard, because it is not of so hot a nature. Burnet bears seed twice a year, and will afterwards yield a good spring crop.

It is not only good for horses, but also for all manner of cattle; even for swine: and Mr. Rocque has experienced another virtue in it, which is, that, being stung by a wasp, the leaves of this plant rubbed pretty hard upon the part so injured, immediately took off the inflammation.

Mr. Worlidge mentions as another excellent quality of this plant, that all good housewives hold, as an infallible rule, that there never need be bad cheese or butter, but especially cheese, where faxifrage grows: "from whence," adds he, "it cometh, that the Netherlands abound much in that commodity, and only, as is supposed, through a plenty of this herb." *Mill's Husbandry.*

BURNING, the action of fire on some pabulum or fuel, whereby the minute parts of those bodies are separated from one another, and put into a violent motion by the action of the fire. See **FIRE**.

BURNING, or **BRENNING**, in our ancient customs, implies an infectious disease, got in the stews by conversing with lewd women; and supposed to be the same with what is now called the venereal disease.

BURNING-GLASSES, are convex or concave, commonly spherical, which being exposed to the sun, do collect all the rays falling upon them into a very small space, called the focus, at a certain distance from the glass in the axis thereof, where wood or any other combustible matter being put, will be set on fire. Metalline concaves, that produce this effect by reflection, are called burning-concaves.

These glasses, by collecting the rays of the sun into a focus, as before-mentioned, do excite a more violent heat, and burn quicker than the hottest wind-furnace; as appears by the melting and calcining the hardest metals, and by vitrifying bricks and stones in much less proportions of time than a minute: yet the rays of the moon being collected by the same glasses do not excite the least sensible heat, nor do they sensibly affect the nicest thermometer when cast upon the ball of it, though the brightness of the light be very much increased. By measuring the breadth of the round image at the focus, and by comparing it with the breadth of the glass itself, it appears that some of these burning-glasses collect the

incident rays into a space about two thousand times less than they possessed at their incidence. But by the preceding calculation, the light of the moon must be condensed about ninety thousand times to make it as dense and as warm as the direct rays of the sun. It is no wonder then that the heat of the moon's rays is not sensible in the focus of the glass, being even then forty or fifty times thinner than the direct rays of the sun. For it is found by experiment, that the degrees of heat are proportionable to the densities of the rays; which being compared with a scale of the degrees of heat and warmth of several natural bodies, determined by Sir Isaac Newton in the Philosophical Transactions, N^o 270. it appears, there is a vast disproportion between the degrees of light which the eye can bear and be sensible of, and the degrees of heat which the touch can bear and be sensible of.

The famous Mr. De la Hire has endeavoured to raise the antiquity of lenses, or lenticular burning-glasses, to a very great height, imagining he has found them among the cloud of Aristophanes, Act II. Sect. 1. where Strepsiades tells Socrates he had found out an excellent contrivance for paying his debts, which was to melt the bond, (which in those days was written on wax) by means of a round transparent stone or glass; which, the scholiast says, they rubbed with oil, and heated it, and then they brought it to a match; and after this manner they lighted the fire. De la Hire cannot understand what the oil was for, unless it was to polish the glass; but be that as it will, he says the scholiast conceived it was convex; which shews, that in his time, though later than Aristophanes, they used such glasses to kindle a fire.

Considering that catoptrics was known and cultivated by the ancients long before dioptrics, it is surprizing they could not account for burning by reflection from a concave metal. Euclid in his catoptrics says, its center is the burning point; because all the rays which pass through it are returned directly back to it. But as the sun's diameter is so small, these rays are but very few, and the consequence would be, that a very broad speculum would burn no better than a narrow one, which is contrary to experience. It is evident from this, and many other blunders in that book, that Euclid, the geometer, was not the author of it; and also that the ancients made very gross experiments.

But since the effects of burning with solid spheres, or glass-bottles filled with water, was so well known to the ancients, how came it to pass that they did not know their effects in magnifying objects? Had the Greek and Latin philosophers known this augmentation of objects, would they not have mentioned it frequently, and would not several metaphors and allusions to it have been brought into their language?

Mr. De la Hire accounts for this oversight of theirs, partly from their false notion about the manner of vision, viz. by certain whimsical emanations from the eye, that went out in quest of objects, or else by little representations in miniature, which came from them, and sought out for our eyes; so that having no suspicion of pencils of rays, nor of our focus's, they could see no analogy between a burning-glass and the manner of vision.

This indeed is a sufficient reason for their not discovering its magnifying power by theory; but can it be supposed they never looked through those spheres? To this our author answers, that the focus of a sphere of glass is at the distance of half the radius from the nearest surface; so that if these spheres had been six inches in diameter, which is the most they can be supposed to be, the object in view must have been placed at one inch and a half from the sphere, to be seen distinctly. But it is natural, and almost necessary, that when any one had looked through these spheres, the objects in view would have been farther off, which, instead of appearing bigger, would only have looked confused. A defined or distinct augmentation of distant objects, requires either very large spheres, which is impracticable, or portions of large spheres, as is now practised with great success. And besides, they must have known how to have wrought and ground their glasses as we do; whereas, in all probability, the ancients only knew how to blow their glass, and make vessels of it.

Among the ancients, the burning-mirrors of Archimedes and Proclus are accounted the most famous; by one of those the Roman ships, besieging Syracuse, under the command of Marcellus, were burnt to ashes; and by the other, the navy of Vitellian, besieging Byzantium; according to Zonaras, Tretzes, Galen, &c.

Kercher, in *Arte magna Lucis & Umbræ*, says, that he found, by experience, the best burning-concaves were such as did not exceed an arch of eighteen degrees in their breadth. If the segments of a greater sphere and a lesser lie each eighteen degrees in breadth, or even something more or less, the number of degrees in both being the same, the effects of the greater segments will be the greatest. Burning-glasses, that are segments of a greater sphere, do burn at a greater distance than those that are segments of a lesser sphere. Manfredus Septala, at Milan, made a parabolic speculum of this kind, that would burn wood at the distance of sixteen paces.

Mr. Villette, at Lyons in France, made a metal-line burning-concave, of a round figure, thirty inches in diameter, and about a hundred pounds weight, the focus, or burning-point, being about three feet distant from the concave, and its bigness about half a louis d'or. This would burn or melt iron in forty seconds, silver in twenty-four, copper in forty-two;

and turned quarry-stone into glass in forty-five, and mortar in fifty-three; and melted a piece of watch-spring in nine seconds.

Mr. Villette afterwards made another, of thirty-four inches in diameter, that would melt all sorts of metals, of the thickness of a crown piece, in less than a minute; and vitrify brick in the same time.

In the Philosophical Transactions, N^o 188. we find mentioned a copper burning-concave, made at Luface, in Germany, of near three Leipzick ells in diameter, and its focus two ells off; being scarce twice so thick as the back of a common knife, and whose force is incredible: for a piece of wood put into the focus, flames in a moment; a piece of lead or tin, three inches thick, will be melted quite through in three minutes time; a piece of iron or steel is presently red-hot, and soon after hath a hole burnt through it. Copper, silver, &c. applied to the focus, melt; and the iron or steel aforesaid melt in five minutes; slate in a few minutes will be turned into black glass; as will tiles, earthen potsherds, bones, &c.

Mr. Tschirhausen is said to have made convex burning-glasses, of three or four feet in diameter, and whose focus is twelve feet distant, and of an inch and a half in diameter; and, to make this focus still stronger, he contracts it by a second lens, placed parallel to, and at a due distance from the first, and so makes the focus but eight lines in diameter. This glass vitrifies tiles, slates, pumice-stones, &c. in a moment. It melts sulphur, pitch, and all resins under water; any metal exposed to it in little lumps, upon a coal, melt in a moment; and iron sparkles as in a smith's forge: all metals vitrify on a piece of China-plate, if it be not so thin as to melt itself; and gold, vitrified, receives a purple colour.

Sir Isaac Newton presented a burning-glass to the Royal Society, consisting of seven concave-glasses, so placed, as that all their foci join in one physical point, each glass being about eleven inches and a half in diameter. Six of them are placed round the seventh, to which they are all contiguous; and they compose a kind of segment of a sphere, whose substance is about thirty-four inches and a half, and the central glass lies about an inch further in than the rest; the common focus is about twenty-four inches and a half distant, and about half an inch in diameter. This glass vitrifies brick, tile, &c. in a moment, and in about half a minute melts gold. A certain artificer of Dresden is said to have made very large burning-concaves of wood, whose effects were little inferior to those made by Tschirhausen. It is likewise said, that one Newman, at Vienna, in the year 1699, made a burning-speculum of stiff-paper, and straw glued to it. And Zacharias Traberus, in Nervo, optician, says, that very large burning-speculums may be made of thirty, forty, or more concave

cave speculums, or square pieces of glass, conveniently placed together in a large turned wooden concave or dish; and that their effect will not be much less than if the superficies were contiguous.

Mr. De Buffon made one in the above manner, consisting of 168 small mirrors, or flat pieces of looking-glass, each six inches square, by means of which, with the faint rays of the sun, in the month of March, he set on fire boards of beech-wood at a hundred and fifty feet distance. Besides, his machine has the convenience of burning downwards, or horizontally, as one pleases; each speculum being moveable, by the means of three screws, to be set to a proper inclination for directing the rays to the given point: and it turns in its greater focus, or in any nearer interval, which our common burning-glasses cannot do, their focus's being fixed and determined. Mr. Buffon, at another time, burnt wood at the distance of two hundred feet; he also melted lead at the distance of above one hundred and twenty feet, and silver at fifty.

In order to account for the nature of burning-glasses, whether mirrors, or lenses, we must consider the area of their surfaces, and the focal distance; because both these qualities enter into the expression of their power of burning. The number of incident rays is as the area of the mirror or lens, and the area of the small space into which the rays after reflection or refraction are concentrated in the focus; being inversely as the square of the focal distance, it follows that the density of the rays, or power of burning, will be as the area of the glass directly, and the square of the focal distance inversely; and, consequently, if a and b represent the areas of two proposed burning-glasses, whose focal distances are d and c respectively, then will p , the power of burning in the greater, be to q , the power of burning in the lesser, as acc to bdd ; hence we get $pbdd = qacc$, from whence the ratio of a to b , or that of d to c , may also be determined. See LENS, MIRROR, REFRACTION, &c.

BURNING of Land, a very great improvement in husbandry, and is not only at this time used in many parts of this and other kingdoms, but it has been practised from the earliest times. Virgil very expressly mentions, and greatly recommends it; and all the old writers of husbandry say much in its praise.

It does not take effect, however, in all sorts of ground. It is not proper for rich soils, nor for stony or chalky ones; nor is it a practice often to be repeated on any land, especially where the surface is very shallow; nor must corn be sown too long upon the land afterwards; for burning exhausts the good juices of the land, in some degree, as well as the bad ones. It is most profitably used to such lands as have laid a long time uncultivated, and over-run with rank weeds, such as four grass, fern, heath, furze, and the like. Some lands, when corn is

sown upon them, run it up into straw, and make the ears but poor and light; these are, beyond all others, improved by burning. The usual methods of ploughing up for this is with a breast-plough, which a man pushes before him, and cuts the turf off the surface, turning it over when he has cut it to about eighteen or twenty inches long. The common way is only to pare it about half an inch thick; but if it be very full of weeds, with stubborn roots, it is better to go deeper.

If the season proves dry, the turf needs no more turning, but dries as it lies. If it be wet, it is necessary to set it on edge, and keep it hollow till such time as the wind and air have sufficiently dried it. It is then to be piled up in little heaps, about the quantity of two wheel-barrows full in each heap; and if there be much roots and a good head upon it, there needs no farther care but setting it on fire, and the whole heap will be reduced to ashes; but if it be earthy and too dead to burn out by itself, there must be a heap of furze or heath laid under every parcel.

When the heaps are reduced to ashes, they are left upon the place till some rain comes to wet them; otherwise, in the spreading, they would all blow away. When they are wetted, the farmer takes the opportunity of a calm day, and spreads them as equally as possible over the whole land, cutting away the earth a little under the heaps, to abate its over-great fertility there. After this, the land is to be ploughed but very shallow, and the corn is to be sown upon it only in half the quantity that it is upon other land; and the later this is sown the better. If it be wheat, the best time is the latter end of October; for if sown sooner, it is apt to grow too rank. The beginning of May is the proper time for cutting the turf off from these lands, because there is then time sufficient to get the land in order for sowing at the proper season. The whole charge of cutting, carrying, and burning the turf, is generally about twenty-four shillings an acre.

The turf is not to be burnt to white ashes; for this wastes a great part of its salt; it is only to be burnt so as to crumble all to pieces, and be in a condition to spread well upon the land; and it is better that the heaps of it should burn slowly and gradually than furiously.

Some farmers stub up furze, heath, and the like, and, covering heaps of them with the parings of the earth, set fire to them; others burn the stubble of the corn-fields; and others the stalks of all sorts of weeds, and add half a peck of unslaked lime to every bushel of ashes. They cover the lime with the ashes, and leave heaps in this manner till there comes some rain to slake the lime; and after this, they spread the mixture carefully over the field. There is one great advantage attending this sort of manure, which is, that it does not breed weeds like the common way with dung, but only fill the ears

of the corn, not running them up into stalk; but it is proper to add some dung to these lands at the time of ploughing them up for a second or third crop of corn. *Mortimer's Husbandry.*

BURNING, in enamel painting. See **ENAMEL Painting**.

BURNISHER, a round polished piece of steel, serving to smooth and give a lustre to metals.

Of these there are different figures, straight, crooked, &c. Half burnishers are used to folder silver, as well as to give a lustre. See the article **SOLDERING**.

BURNISHING, the art of smoothing or polishing a metalline body, by a brisk rubbing of it with a burnisher.

BURR, the round knob of a horn next a deer's head.

BURSA-PASTORIS, shepherd-pouch, in botany, a plant which grows wild in many parts of England: it hath a white, straight, fibrous, slender root, with a stalk which rises about a foot high; the lower-leaves are jagged like dandelion; but those which grow on the stalks are less broad, with even edges, and terminate in a point: the flowers are placed in rows on the top of the branches, and are small and cruciform; they consist of four roundish petals, with six small stamina, two of which are shorter than the others; the fruit is in the shape of a heart or purse, and is divided into two cells, containing two or three seeds in each. This plant is said to be a vulnerary astringent, cooling herb, and is given in hæmorrhages and fluxes: the country people, with good success, apply it to cuts and fresh wounds; and it is reported to cure quartan and tertian agues, if made into a cataplasm, and applied to the wrists just before the coming on of the fit. This plant is classed by Linnæus with the thlaspi. See the article **THLASPI**.

BURSERA, in botany, a genus of hexandrious plants; the flower consists of three plane ovated sharp-pointed petals, with six upright awl-shaped filaments, topped with oblong antheræ; the germen is egg-shaped, and turns to a capsule of the same form, which contains a single baccated compressed seed.

BURTON, a sort of small taicle made by two blocks or pulleys till the rope becomes three or four-fold, and acquires an additional power in proportion.

It is used to draw tight the top-mast shrouds; and may be otherwise employed to move, or draw along, any weighty body on the deck, or in the hold; as, anchors, bales of goods, &c.

BUSH, in botany, a term used for divers sorts of low growing shrubs; thus we say a gooseberry-bush, a currant-bush, a furze-bush, &c. it is also used when there is an assemblage of branches growing interwoven, or mixed together.

BUSHEL, a measure of capacity for dry things; as, grain, fruits, dry pulse, &c. containing four pecks, or eight gallons, or one-eighth of a quarter.

A bushel, by 12 Henry VII. c. 5. is to contain eight gallons of wheat; the gallon eight pounds of troy-weight; the ounce twenty sterlings, and the sterling thirty-two grains, or corns of wheat growing in the midst of the ear. See the articles **MEASURE** and **WEIGHT**.

At Paris, the bushel is divided into two half bushels; the half bushel into two quarts; the quart into two half quarts; the half quart into two litrons; and the litron into two half litrons.

BUSKIN, a kind of shoe, somewhat in manner of a boot, and adapted to either foot, and worn by either sex.

This part of dress, covering both the foot and mid-leg, was tied underneath the knee; it was very rich and fine, and principally used on the stage by actors in tragedy. It was of a quadrangular form, and the sole was so thick, as that by means thereof, men of the ordinary stature might be raised to the pitch and elevation of the heroes they personated. The colour was generally purple on the stage; and was distinguished from the sock, worn in comedy, that being only a low common shoe. The buskin seems to have been worn, not only by actors, but by girls, to raise their height; travellers and hunters also made use of it, to defend themselves from the mire.

In classic authors, we frequently find the buskin used to signify tragedy itself, in regard it was a mark of tragedy on the stage.

It is also used to imply a lofty strain, or high style.

BUSS, in maritime affairs, a small sea-vessel, used by us and the Dutch in the herring-fishery, commonly from forty-eight to sixty tons burden, and sometimes more: a buss has two small sheds or cabins, one at the prow, and the other at the stern; that at the prow serves for a kitchen.

BUST, or **BUSTO**, in sculpture, &c. a term used for the figure or portrait of a person in relief, shewing only the head, shoulders, and stomach, the arms being lopped off: it is usually placed on a pedestal, or console.

BUSTARD, in ornithology, the English name of a genus of birds, called by authors *otis*. See **OTIS**.

BUSTUARI, in Roman antiquity, gladiators who fought about the bustum, or funeral pile of a deceased person of distinction, in the ceremony of his obsequies.

BUTCHER-BIRD, in ornithology, the English name of the *lanius*. See **LANIUS**.

BUTCHER'S-BROOM, *Ruscus*, in botany. See the article **RUSCUS**.

BUTLER, *Buticularius*, the name anciently given to an officer in the court of France, being the

the same as the grand echanfon, or great cup-bearer of the present times.

BUTLER, in the common acceptance of the word, is an officer in the houses of princes and great men, whose principal business is to look after the wine, plate, &c.

BUTMENTS, in architecture, those supporters or props on or against which the feet of arches rest. See **BRIDGE**.

BUTMENT is also the term given to little places taken out of the yard or ground-plot of a house, for a buttery, scullery, &c.

BUTOMUS, in botany, an aquatic plant which grows common in standing-waters in several parts of England; the flower of which consists of six roundish concave petals, alternately exterior, smaller, and more acute; with nine subulated filaments, topped with double lamellated antheræ: the fruit consists of six oblong-pointed erect capsules of one valve, containing several oblong cylindric seeds, obtuse at both ends. It is said to be of an aperient and deobstruent quality.

BUTT, in naval architecture, the end of any plank in a ship's side which unites with the end of another: when a plank is loosened at the end by the ship's weakness or labouring, she is said to have started, or sprung a butt.

BUTTER, a fat unctuous substance, prepared or separated from milk by churning it. For the manner of making butter, see the article **DAIRY**.

The word is formed from the Greek, *βουτυρον*, which is compounded of *βου*, a cow, and *τερον*, cheese.

BUTTER, among chemists, a name given to several preparations, on account of their consistence resembling that of butter; as, butter of antimony, of arsenic, of wax, of lead, of tin, &c.

BUTTER-BUMP, in zoology, a bird of the heron kind, more usually called bittern. See the article **BITTERN**.

BUTTER-BUR, in botany. See the article **PETASITES**.

BUTTERFLY, the English name of a numerous genus of insects, called by zoologists papilio. See **PAPILIO**.

BUTTERFLY-FISH, a species of the blennius of ichthyologists, with a furrow between the eyes. It is common in the American seas.

BUTTERFLY-FLOWERS, in botany, the same as papilionaceous-flowers; they compose the seveneenth class in the Linnean system of botany; such are the blossoms of the pea, bean, broom, lupine, and various others.

BUTTERIS, in the manege, an instrument of steel, fitted to a wooden-handle, wherewith they pare the foot, or cut the hoof of a horse.

BUTTER-MILK, a kind of serum that remains behind, after the butter is made. Of this

curds may be made, which are good when eat either with cream, wine, ale, or beer. And the whey, kept in a clean strong vessel, is an excellent cooling, wholesome drink, to be used in the summer instead of other drink, and will quench the thirst better than beer.

Butter-milk is esteemed an excellent food, in the spring especially, and is particularly recommended in hectic fevers.

BUTTER-WORT, in botany. See the article **PINGUICULA**.

BUTTERY, a room in the houses of noblemen and gentlemen, belonging to the butler, where he deposits the utensils belonging to his office, as table-linen, napkins, pots, tankards, glasses, cruets, salvers, spoons, knives, forks, pepper, mustard, &c.

BUTTOCK, in naval architecture, the round parts of a ship behind, under the stern, terminated by the counter above, and the after-part of the bilge below.

BUTTON, an article in dress, whose form and use are too well known to need description.

Buttons are made of various materials, as mohair, silk, horse-hair, metal, &c.

Method of making common BUTTONS. Common buttons are generally made of mohair; some indeed are made of silk, and others of thread; but the latter are a very inferior sort. In order to make a button, the mohair must be previously wound on a bobbin; and the mould fixed to a board by means of a bodkin thrust through the hole in the middle of it. This being done, the workman wraps the mohair round the mould in three, four, or six columns, according to the button.

Horse-Hair BUTTONS. The moulds of these buttons are covered with a kind of stuff composed of silk and hair; the warp being belladine silk, and the shoot horse-hair. This stuff is wove with two selvages in the same manner, and in the same loom as ribbands. This stuff is cut into square pieces proportioned to the size of the button, wrapped round the moulds, and their selvages stitched together, which form the under part of the button.

Cleaning of BUTTONS. A button is not finished when it comes from the maker's hands; the superfluous hairs and hubs of silk must be taken off, and the button rendered glossy and beautiful, before it can be sold. This operation is performed in the following manner:

A quantity of buttons are put into a kind of iron sieve, called by workmen a singing-box. Then a little spirit of wine being poured into a shallow iron-dish, and set on fire, the workman moves and shakes the singing-box, containing the buttons, briskly over the flame of the spirit, by which means the superfluous hairs, hubs of silk, &c. are burnt off, without damaging the buttons. Great care however must be taken that the buttons in the singing-box

box be kept continually in motion; for if they are suffered to rest over the flame, they will immediately burn.

When all the loose hairs, &c. are burnt off by the flame of the spirit, the buttons are taken out of the singeing-box, and put, with a proper quantity of the crumbs of bread, into a leather-bag, about three feet long, and of a conical shape; the mouth or smaller end of which being tied up, the workman takes one of the ends in one hand, and the other in the other, and shakes the bag briskly, with a particular jerk. This operation cleanses the buttons, renders them very glossy, and fit for sale.

Gold-Twist Buttons. The mould of these buttons is first covered with the silk in the same manner as that of common buttons. This being done, the whole is covered with a thin plate of gold or silver, and then wrought over in different forms with purple and gimp. The former is a kind of thread composed of silk and gold-wire twisted together; and the latter, capillary tubes of gold or silver, about the tenth of an inch in length. These are joined together by means of a fine needle filled with silk, thrust through their apertures, in the same manner as beads or bugles.

The manner of making Metal Buttons. The metal with which the moulds are intended to be covered is first cast into small ingots, and then flattened into thin plates or leaves, of the thickness intended, at the flattening-mills; after which it is cut into small round pieces proportionable to the size of the mould they are intended to cover, by means of proper punches on a block of wood covered with a thick plate of lead. Each piece of metal thus cut out of the plate is reduced into the form of a button, by beating it successively in several cavities, or concave moulds, of a spherical form, with a convex puncheon of iron; always beginning with the shallowest cavity or mould, and proceeding to the deeper, till the plate has acquired the intended form: and the better to manage so thin a plate, they form ten, twelve, and sometimes even twenty-four to the cavities, or concave moulds, at once; often nealing the metal during the operation, to make it more ductile. This plate is generally called by workmen the cap of the button.

The form being thus given to the plates, or caps, they strike the intended impression on the convex side by means of a similar iron puncheon in a kind of mould engraven en creux, either by the hammer, or the press used in coining. The cavity of mould, wherein the impression is to be made, is of a diameter and depth suitable to the sort of button intended to be struck in it; each kind requiring a particular mould. Between the puncheon and the plate is placed a thin piece of lead, called by the workmen a hob, which greatly contributes to the taking off all the strokes of the engraving; the lead, by reason of its softness, easily giving way to

the parts that have relieve; and as easily insinuating itself into the traces or indentures.

The plate thus prepared makes the cap or shell of the button. The lower part is formed of another plate, in the same manner, but much flatter, and without any impression. To the last or under plate is soldered a small eye made of wire, by which the button is to be fastened.

The two plates being thus finished, they are soldered together with soft solder, and then turned in a lathe. Generally indeed they use a wooden mould instead of the under plate; and in order to fasten it, they pass a thread or gut across, through the middle of the mould, and fill the cavity between the mould and the cap with cement, in order to render the button firm and solid; for the cement entering all the cavities formed by the relieve of the other side sustains it, prevents its flattening, and preserves its bobe or design.

Button-Mould, the piece of wood, &c. covered with mohair, silk, metal, &c.

Manner of making Button-Moulds. The wood is first sawn into pieces of a proper thickness; and then the moulds turned out of these pieces by means of tools called piercers, of various forms and dimensions, according to the nature and size of the moulds intended to be made. If the moulds are very small, they are turned in a small lathe, by means of a bow; but if large, in a lathe turned by a wheel, as one man cannot turn the lathe with his foot, and manage the block of wood at the same time; at least not with that facility or dispatch as in the other manner.

Button-Tree, in botany. See the article **CO-NOCARPUS**.

Button-Weed. See **SPERMACEOE**.

Button-Wood. See **CEPHALANTHUS**.

Button, in fencing, signifies the end or tip of a foil, being made roundish, and usually covered with leather, to prevent making contusions in the body.

Button, in building, denotes a slight fastening for a door or window, made to turn on a tail.

Button of the Reins of a Bridle, is a ring of leather, with the reins put through it, running all along the length of the reins.

Button, Antennæ, a name given by naturalists to those antennæ, or horns, as they are called, of butterflies, which are slender, and terminated at the top by a sort of button, in form of an olive, or part of one.

BUTTRESS, a kind of butment built archwise, or a mass of stone or brick, serving to prop or support the sides of a building, wall, &c. on the outside, where it is either very high, or has any considerable load to sustain on the other side, as a bank of earth, &c.

Buttresses are used against the angles of steeples and other buildings of stone, &c. on the outside,
and

and along the walls of such buildings as have great and heavy roofs, which would be subject to thrust the walls out, unless very thick, if no buttresses were placed against them: they are also placed for a support and buttment against the feet of some arches that are turned across great halls, in old palaces, abbeyes, &c.

The theory and rules of buttresses are one of the desiderata in architecture; but the size and weight of them ought to be in proportion to the dimensions and form of the arch, and the weight which is superincumbent on it.

As to the weight of the materials, both on the arch and in the buttress, it is not difficult to calculate: but it may be objected, that there may be a sensible difference as to the strength and goodness of the mortar, which may, in some measure, compensate for the weight of the buttress. See **BRIDGE**.

BUXUS, the box-tree, in botany, a genus of ever-green shrubs; the branches are numerous and furnished with oblong, small, hard, thick, shining leaves, of a disagreeable bitterish smell and taste; the flowers are male and female, produced on the same plant; the male flowers have a three-leaved concave empalement, with two roundish petals, in which are inserted four awl-shaped filaments, topped with double erect antheræ. The female flower hath a tetraphyllous calyx, with three concave roundish petals, in which is placed a three-cornered, obtuse, roundish germen, supporting three very short styles, crowned with obtuse prickly stigma. The fruit is shaped like a pottage-pot inverted; of a green colour, divided into three cells, containing each two oblong seeds, which, when ripe, are thrown out by the elasticity of the vessels; these are brown, long, and of a shining colour. There are three species of box noticed by botanists; one of which, called the dwarf, or Dutch box, is much used for edging of flower-beds, or borders, for which purpose it exceeds all other plants, as it will bear the extremes of heat and cold, is more lasting, and will grow in almost any soil. This is easily increased, by parting the roots: the season for planting in dry lands is in September, and in moist soils in March. The other species grow in divers parts of England, particularly on Box-hill in Surrey, and are of a considerable size. The wood of these trees is of a yellow colour, and more compact and ponderous than any of the other European woods, and is therefore of considerable use to turners, engravers, and mathematical instrument-makers, it being so hard and close as to sink in water, which renders it very valuable for divers utensils. Box is seldom used in medicine, though some pretend it has the same virtues as guaiacum. The oil

distilled from the wood is a great narcotic, and is sometimes used for the tooth-ach, by putting a drop into a hollow rotten tooth.

BUZZARD, *Buteo*, in ornithology, the English name of several species of the hawk-kind, distinguished from each other by particular epithets; as, 1. The bald buzzard, with blue legs. 2. The common buzzard. 3. The honey buzzard. 4. The subbuteo, or the hen-harrier, and the ring-tail. 5. The moor-buzzard, &c.

BY-LAWS, or **BYE-LAWS**, private and peculiar laws for the good government of a city, court, or other community, made by the general consent of the members.

BYRLAW, or **BURLAW-LAWS**, in Scotland, are made and determined by neighbours elected by common consent in byrlaw-courts. The men, chosen as judges, are called byrlaw, or burlawmen, and take cognizance of complaints between neighbour and neighbour.

BYSSUS, in botany, a genus of mosses, consisting of plain, simple, capillary filaments.

The byssus is the most imperfect of all vegetables, no part of its fructification having been hitherto discovered: its filaments are uniform, and often so fine as to be scarce discernible singly; tho' in a cluster, they make a kind of fine down. Botanists are not agreed whether the byssus be properly a moss or fungus. Linnæus is of the latter opinion, and the generality of botanists of the former. Dillenius thinks it is of a middle nature, between both.

This difference of opinion probably arose from hence, that authors have confounded two very distinct vegetables under the name byssus; the one, the filamentose bodies, described above, which are the only true byssi; and the other, the dusty matter found on rotten vegetables, consisting of small globules. The byssi are nearly allied to the conservæ; from which however they differ, as consisting of finer, shorter, and more tender filaments, and not growing in water as the conservæ do.

Byssus, in antiquity, that fine Egyptian linen whereof the tunics of the Jewish priests were made.

Philo says, that the byssus is the clearest and most beautiful, the whitest, strongest, and most glossy sort of linen; that it is not made of any thing mortal, that is to say, of wool, or the skin of any animal, but that it comes out of the earth, and becomes still whiter, and more shining, every time it is washed as it should be.

BYTTNERIA, in botany, a genus of pentandrous plants, whose flower consists of a monophyllous cup, divided into five parts, with five short oblong petals; the fruit is a depressed roundish capsule, containing an ovate compressed seed.

BYZANT, or **BEZANT**. See **BEZANT**.

C.

C A B

C A B

C, The third letter and second consonant of the alphabet, is pronounced like *k*, before the vowels *a*, *o*, and *u*; but like *s*, before *e* and *i*.

As an abbreviature, C stands for Caius, Carolus, Cæsar, condemnno, &c. and CC for *consulibus*.

As a numeral, C signifies 100, CC 200, &c.

C, in music, placed after the cliff, intimates, that the music is in common time, which is either quick or slow, as it is joined with *allegro* or *adagio*: if alone, it is usually *adagio*.

If the C be crossed or turned, the first requires the air to be played quick, and the last very quick.

CAABA, a square stone edifice in the temple of Mecca, supposed to have been built by Abraham and his son and Ishmael; being the part principally revered by the Mahometans, and to which they always direct themselves in prayer.

The word is Arabic, caaba, and caabah, a denomination which some will have given to this building, on account of its height, which surpasses that of the other buildings in Mecca; but others, with more probability, derive the name from the quadrangular form of the structure itself.

CAAMINI, in botany, the name by which the Spaniards call the finer kind of Paraguay-tea. See the article PARAGUAY.

CAAPEBA, in botany. See the article CRISAMPELUS.

CAB, or KAB, a Hebrew measure of capacity, equal to the sixth part of the seah, or an eighteenth of the ephah.

The cab of wine contained two English pints; the cab of corn $2\frac{1}{2}$ pints, corn measure.

CABALA *Vein*, in natural history, a name given by our Suxlex miners to one kind of the iron ore commonly wrought in that country. It is a stony ore, of a brownish colour, with a bluish of red, which is more or less conspicuous in different parts of the same masses.

CABALLINE denotes something belonging to horses: thus caballine aloes is so called from its being chiefly used for purging horses; and common brimstone is called sulphur caballinum for a like reason.

CABBAGE, *Brassica*, in botany, a genus of tetradynamious plants, the flowers of which are tetrapetulous and cruciform: the pistil which arises

from the cup becomes afterward a long taper pod depressed on each side, and is terminated by the apex of the intermediate partition, which divides it into two cells filled with a number of round seeds.

There are divers species belonging to this family of plants; as also several varieties belonging to some of the species, occasioned by different soils and culture; such as the Savoy cabbage, the red cabbage, the early cabbage, the fugar-loaf cabbage, the musk cabbage, the Russian cabbage, besides the cauliflower, brocoli, borecole, colewort, and Scotch kale; but those which turns in and hardens firm, is (according to the common acceptance of the word) called cabbage. This plant being a principal vegetable for our common food, it may not be amiss to mention their culture, and first of the favoy; this sort (as likewise the others) is propagated by sowing the seeds; the season for favoys is to sow in the month of April, and some in May; and when the young plants have about six or eight leaves, they should be planted into beds about four inches asunder; (though this practice is omitted by the kitchen-gardeners, who raise great quantities for sale, they planting them immediately from the seed-bed into the places they are to perfect themselves) these plants by the time beans, &c. are grown to their size, are planted between the rows, which affords them a good shade, until they are well rooted, at which time the former crop is cleared away; these should be planted at two feet and a half asunder. The red cabbage is so hardy, that it will resist the severest frosts: though it is not much used in the manner the others are, yet is the most proper of any for pickling, and may be sown in the spring, and managed as the former.

The early or Battersea cabbage (as it is called) is sown for summer use, the season for doing which is the beginning of July, and afterwards planted in beds, where they may remain till October, and then taken up and planted for good, at the distance of three feet row from row, and two feet and a half asunder in the rows. In May and June this sort begins to turn in their leaves for cabbaging, and in order to obtain them a little sooner, the gardeners tie in their leaves close with a slender twig to blanch their middle, by which means they have them a fortnight earlier than those which turn naturally. The sugar-loaf cabbage requires the

same

same management and season as the early fort, and comes into use when those are either cut or become so hard as not to be fit for the table. The musk cabbage is much tenderer than the other sorts, and is therefore but little cultivated. The Russian cabbage is but little noticed at present; this sort is small and hard, and may be sown in the spring, and fit for use in July and August. The borecole may be treated in the same manner as the savoy, but need not be planted above a foot asunder in the rows, and the rows two feet distance. These are never eaten till the frost hath rendered them tender, for otherwise they are tough and bitter. The colewort has of later years been very little propagated, the common cabbage plants being substituted in their stead; those are tied up in bunches, and sold in the London Markets, and are all called coleworts, let them be of what sort they will. The Scotch kale, or Siberian borecole, is extremely hardy, and is always sweeter in the severe winters than in milder seasons; this is propagated by sowing the seeds in July, and afterwards transplanted at about a foot and a half asunder. These are fit for use from Christmas till April; a variety of this sort is finely coloured, and is very ornamental in shrubberies during the winter. To this genus Linnæus has added the turnip, navew, and rocket; which see explained under their respective articles; also the CAULIFLOWER and BROCOLI.

CABBAGE-TREE, *palmæ maxima*, or *palmeto royal*, a very beautiful tree, common in several parts of America.

It has acquired the name of royal from its remarkable height, majestic appearance, and elegance of its waving foliage: neither the tall cedars of Lebanon, nor any of the trees of the forest, are equal to it in height, beauty, or proportion.

Its roots are innumerable, resembling so many round thongs, of a regular determinative bigness, seldom exceeding the size of the little finger, but of a great length, penetrating some yards into the earth, especially where the soil is sandy, or otherwise porous: these roots are of a dark-brown colour.

The trunk jets, or bulges out a little near the ground, by which means it hath the becoming appearance of a substantial basis to support its towering height. It is generally as straight as an arrow; and scarce can a pillar of the nicest order in architecture be more regular, especially when it is of about thirty years growth: and as there is a natural involuntary pleasure arising from the harmony of just geometrical proportions, striking the eye of the most unskilful and ignorant beholder, it is not strange that these trees are universally admired.

Writers of wonders represent some of them to be three hundred feet in height: however, Mr. Hughes informs us, that in Barbadoes, where they are more numerous than in the other islands, that

they do not exceed one hundred and thirty-four feet.

The trunk of this tree, near the earth, is about seven feet in circumference, the whole body growing tapering to the top.

The substance of the tree, for about two or three inches of the outside, but within the bark, is of a blackish colour, and extremely hard and solid: this surrounds the inner substance, which is a whitish pith, intermixed with some small veins of a more ligneous texture.

The colour of the bark much resembles that of an ash tree, and is very faintly clouded, at about the distance of every four or five inches, with the vestigia of the fallen-off branches: this colour of the bark continues till within about twenty-five or thirty feet of the extremity of the tree: there it alters at once from an ash-colour to a beautiful deep sea-green, and continues to be of that colour to the top.

About five feet from the beginning of the green part upwards, the trunk is surrounded with its numerous branches in a circular manner; all the lowermost spreading horizontally with great regularity; and the extremities of many of the higher branches bend wavily downwards, like so many plumes of feathers. These branches, when full-grown, are twenty feet long, more or less; and are thickly set on the trunk alternately, rising gradually superior one to another: their broad curved sockets so surround the trunk, that the sight of it, whilst among these, is lost, which again appears among the very uppermost branches, and is there enveloped in an upright green conic spire, which beautifully terminates its greatest height.

The above-mentioned branches are somewhat round underneath, and slightly grooved on the upper side: they are likewise decorated with a very great number of green pennated leaves; some of these are near three feet long, and an inch and a half broad, growing narrower towards their points, as well as gradually decreasing in length towards the extremities of the branches.

As there are many thousand leaves upon one tree, every branch bearing many scores upon it, and every leaf being set at a small and equal distance from one another, the beauty of such a regular lofty group of waving foliage, susceptible of motion by the most gentle gale of wind, is not to be described.

The middle rib, in each leaf, is strong and prominent, supporting it on the under side, the upper appearing smooth and shining. The pithy part of the leaf being scraped off, the inside texture appears to be so many longitudinal thread-like filaments.

These being spun in the same manner as they do hemp, or flax, are used in making cordage of every kind, as well as fishing-nets, which are esteemed stronger than those usually made from any other material of the like nature.

It is observed, that the lowermost branch, for the time being, drops monthly from the tree, carrying with it an exfoliated circular lamen of the green part of the tree, from the setting on of the branches, to the ash-colour part, which is about five feet in length, and in breadth the circumference of the tree at that part. This, and the branch to which it is always fixed, fall together.

When the loss of this lower branch happens, then the green conic spire, which issues from among the center of the uppermost branches, and rises superior to all, partially bursts, and thrusts from its side a young branch, which continues the uppermost, till another of the lowermost branches drop off: then, the spire, the common parent of all the branches, sends forth again another branch, superior in situation to the last; so that the annual loss of the branches below is providentially supplied in this manner by those above.

The green-coloured part of the tree, already mentioned, differs from the ash-coloured part no less in substance than colour; the former, instead of being extremely hard on the outside, and pithy within, is composed of so many coats, or separate laminae, of a tough bark-like substance, of near a quarter of an inch thick, and so very closely wrapped together, that they jointly compose and constitute that green part of the tree.

As the lowermost, as well as each other higher branch, when they successively grow to be old, is joined by the broad socket of its foot-stalk to this outward coat, lamen, or folding, it is observable, that some time before the lowermost branch is entirely withered, this green circular coat, which to the eye appeared some days before to be a solid part of the tree, splits open lengthwise, from the setting on of the branches to the ash-coloured part beneath, being about five feet in length, and the circumference of the tree in the breadth; and, peeling off, it falls with the falling branch to which it is joined by many strong cartilages, leaving the next succeeding coat to appear for a time as a constituent part of the tree, till a succeeding withered branch carries this off likewise.

Mr. Hughes farther informs us, that having felled one of these stately trees, to examine its make, texture, &c. he observed, that the several exfoliations of its green part were equal in number to the branches.

The first, second, third, and sometimes the fourth of these laminae are green on the outside, and perfectly white within: all the remaining inner coats, or foldings, are of a bright lemon-colour without, and white within.

When these very tough husky exfoliations are taken off, what is called the cabbage, lies in many thin, snow-white, brittle flakes; in taste something like the kernel of an almond, but sweeter: it is so full of oil, that a curious observer may see several

very small cells abounding with it. These flakes are called, from some resemblance, when boiled, the cabbage, which then eats somewhat sweet and agreeable.

What is called the cabbage-flower grows from that part of the tree where the ash-coloured trunk joins the green part already described. Its first appearance is a green husky spatha, growing to above twenty inches long, and about four broad; the inside being full of small white stringy filaments, full of alternate protuberant knobs, the smallest of these resembling a fringe of coarse white thread knotted: these are very numerous, and take their rise from larger footstalks; and these footstalks likewise are all united to different parts of the large parent stalk of all.

As this husky spatha is opened, while thus young, the farinaceous yellow seed, in embryo, resembling fine saw-dust, is very plentifully dispersed among these stringy filaments, which answer the use of apices in other more regular flowers: these filaments, being cleared of this dust, are pickled, and esteemed among the best pickles in Europe.

But if this spatha is not cut down and opened, whilst thus young, if it be suffered to continue on the tree till it grows wild and bursts; then the inclosed part, which, whilst young and tender, is fit for pickling, will by that time have acquired an additional hardness, become soon after ligneous, grow bushy, consisting of very small leaves, and in time produce a great number of small oval thin-shelled nuts, about the bigness of unhusked coffee-berries: these, being planted, produce young cabbage-trees.

CABBAGING, among gardeners, a term used for several plants, whose leaves turn in, and become hard like a cabbage.

CABBALA, among the Jews, is properly the mystical-interpretations of their scriptures, handed down by tradition.

The word is Hebrew, and literally signifies traditions.

CABBALISTS, those Jewish doctors who profess the study of the cabbala. In the opinion of these men, there is not a word, letter, or accent, in the law, without some mystery in it. The first cabbalistical author that we know of, is Simon, the son of Joachai, who is said to have lived a little before the destruction of Jerusalem by Titus. His book, entitled Zohar, is extant; but it is agreed that many additions have been made to it. The first part of this work is entitled Zenintha, or Mystery; the second Idra Rabba, or the Great Synod; the third Idra Lata, or the Little Synod, which is the author's last adieu to his disciples. See RABBINS.

CABECA, or CABESSE, a name given to the finest silks in the East-Indies, as those from 15 to 20 per cent. inferior to them are called barina. The Indian workmen endeavour to pass them off one

with the other; for which reason the more experienced European merchants take care to open the bales, and to examine all the skins one after another.

CABIN, in naval architecture, a room or apartment for any of the officers of a ship to sleep and dress in, &c.

There are many of these in large ships, the principal of which is designed for the captain or commander; and this in ships of the line is furnished with an elegant gallery in the stern. See the article **GALLERY**.

When any bed-places are built up at the sides of a ship, which is frequently the case in merchantmen, they are also called cabins.

CABINET, a piece of joiners workmanship. It is a kind of press or chest, with several doors and drawers, to lock up the most precious things, or only to serve as an ornament in chambers, galleries, or other apartments.

CABINET, in a garden, is a conveniency which differs from an arbour in this; that an arbour or summer-house is of a great length, and arched over head, in the form of a gallery; but a cabinet is either square, circular, or in cants, making a kind of saloon to be set at the ends, or in the middle of a long arbour.

CABINET of Natural History, a building containing all the curiosities of nature, digested in a proper manner.

Such a building might indeed be called, with more propriety, a museum or repository; cabinet here, therefore, must be understood in a larger sense than the common acceptation of the word, as herein are exhibited to our view the animal, vegetable, and mineral kingdoms at once: in short, an epitome of nature.

It is not certain whether the ancients ever formed any collections of this kind, or erected any structures for the reception and disposition of them. But it is not improbable; that Aristotle, supported by the generosity and magnificence of Alexander the Great, built something of this kind, at least with regard to animals; because the observations he has left us, are undoubtedly the result of anatomical observations; and the remarks he has made on the various species of animals, shew our knowledge, even since the revival of letters, to be vastly inferior to his in this respect.

The knowledge of natural history improves, as collections of this kind are made more perfect; and our own age has first set on foot establishments that deserve the name of cabinets of natural history.

CABIRI, a term in the theology of the ancient pagans, signifying great and powerful gods, being a name given to the gods of Samothracia. They were also worshipped in other parts of Greece, as Lemnos and Thebes, where the cabiria were celebrated in honour of them: these gods are said to

be, in number, four, viz. Axieros, Axioerfa, Axioerfus, and Casmilus.

CABIRIA, festivals in honour of the cabiri, celebrated in Thebes and Lemnos, but especially in Samothracia, an island consecrated to the cabiri. All who were initiated into the mysteries of these gods were thought to be secured thereby from storms at sea, and all other dangers. The ceremony of initiating was performed, by placing the candidate, crowned with olive branches, and girded about the loins with a purple ribbon, on a kind of throne, about which the priests and persons before initiated, danced.

CABLE, in the marine, a large strong rope, used to retain a ship at anchor. See the article **ANCHOR**.

Cables are of various kinds and sizes; they are most frequently formed of hemp; some, however, are made of bals, and those are generally the manufacture of Barbary; others are composed of a sort of Indian-grass; and are the product of different parts of Asia.

Every cable, of whatever thickness, is formed of three strands or twists, and each of these made up of three smaller strands; and those last are composed of a certain number of rope-yarns, which number is greater or less, in proportion to the size of the cable required.

All ships have, or ought to have, at least three good cables; the sheet-cable, and the two bowers, best and small.

All cables are, or ought to be, one hundred and twenty fathoms; for which purpose, the threads, or yarns, must be one hundred and eighty fathoms, since they are diminished one-third in length by twisting; but it is often necessary, notwithstanding this length, to splice two cables, at least together, in order to double the length, when there is a necessity to let go the anchor into deep water; for although a ship seldom anchors in above forty fathoms depth, if there is but one cable, the lower part of it will scarce bear on the ground, and the anchor will be obliged to sustain all the shocks and jerks of the ship in a direction too nearly perpendicular, which must of necessity loosen the anchor, so that the ship must drag it, in the seaphrase, and, driving from her station, be in danger of being wrecked on the first rocks, &c. whereas it is evident, that if the length of the cable be doubled, or tripled, the anchor will be dragged more horizontally, and bear a much greater force.

A second advantage is, that, by having several cables at one another's ends, they will be less liable to break; for all the parts lying more upon a level, they will oppose the shocks of the sea in a direction more perpendicular to the motions which the ship receives; whereas, when the cable is not long, it will be nearly vertical to the anchor, and therefore cannot bear such a strain: for it is evident, that

that a shorter cable is charged with a greater effort, and should therefore be stronger; otherwise it will only bear the same strain in the proper direction, and will not be sufficient in an horizontal direction, which is that in which the ship endeavours to drive.

The long cable will not be so apt to break as the short one; because it will bear a great deal more stretching before it comes to the greatest strain: otherwise, being short, it must break at the first violent tug, because it will not bear stretching; for a long cable may be compared to a fort of spring, which may be very easily extended; and recovers its first situation, as soon as the force which extended it is removed. Besides all this, a ship will ride much smoother with a long cable than with a short one, and be less apt to plunge into the water; whereas, when a ship rides with a short cable, as mariners have too often experienced, she frequently pitches all the fore-part under water.

By what has been said on this subject, we may see how very necessary it is to furnish a ship with sufficiency of cables, or what is called ground-tailing; and what an inconsiderate policy it is in merchants to subject their vessels to such evident dangers, from the want of them: for we may venture to assert, without violation of truth, that many good ships have been lost, within our own remembrance, only on account of a deficiency in this article.

CABLE is likewise a general name given to all large ropes which serve to raise heavy loads by means of cranes, pulleys, and other engines; as in bridges of boats: it is seldom given to a rope of less than three inches diameter.

The number of threads each cable is composed of, being always proportioned to its length and thickness, its weight and value are determined by this number of threads: thus a cable of ten inches in circumference ought to consist of four hundred and eighty-five threads, and weigh one thousand nine hundred and forty pounds; and on this foundation is calculated the following table, very useful for all persons engaged in marine commerce, who equip merchant-ships on their own account, or freight them for the account of others.

A Table of the number of threads and weight of cables of different circumferences.

Circumference in inches.	Threads, or rope-yarns.	Weight in pounds.
9	393	1572
10	485	1940
11	598	2392
12	699	2796
13	821	3284
14	952	3808
15	1093	4372
16	1244	4976

Circumference in inches.	Threads, or rope-yarns.	Weight in pounds.
17	1404	5616
18	1574	6296
19	1754	7016
20	1943	7772

Serve the CABLE, is to bind it round with ropes, leather, or other materials, to prevent it from being galled or fretted in the hawse by friction. See *HAUSE*.

Splicing the CABLE, is interweaving the ends of the strands of two cables together, or of one that had been broke.

Pay away the CABLE, is to let more run out of the ship, that the may ride easier.

CABLED, in heraldry, a term applied to a cross, formed of the two ends of a ship's cable; sometimes also to a cross covered over with rounds of rope, more properly called a cross-corded.

CABOCHED, in heraldry, is when the heads of beasts are borne without any part of the neck, full-faced.

CACALIA, foreign coltsfoot, in botany, a genus of syngeneisous plants, producing compound flowers: one of the species grows naturally in Austria, and on the mountains in Switzerland; this hath a fleshy root, which spreads in the ground, from which springs up many leaves, standing on single foot-stalks, and are shaped like those of ground-ivy, but are of a thicker texture, of a shining green on their upper-side, but white underneath; between these arise the stalk, which is round, branching towards the top, and grows to about a foot and a half high; under each division of the stalk is placed a single leaf of the same form as those below, but much smaller: the branches are terminated by purplish flowers, growing in a sort of umbel; these are erect, tubulous, funnel-shaped, and cut at the top into five segments, and are succeeded by oblong seeds, crowned with down.

To this genus Linnæus has added the cacalianthemum, tithymaloides, and porophyllum of other authors.

CACAO, the chocolate-tree, in botany, a genus of trees, called by Linnæus theobroma. See *THEOBROMA*.

The fruit of this tree is an oblong, roundish nut, nearly of the shape of an almond, but larger: the shell is dark-coloured, brittle, and thin: the kernel is both externally and internally brownish, divided into several unequal portions, which are joined firmly together. It is the produce of a small American tree, bearing a large red fruit, shaped like a cucumber, which contains thirty or more of the nuts. There are several sorts of these nuts in the shops, distinguished by their size, and the places whence they are brought: the larger kind, from the province of Nicaragua in Mexico, is most esteemed.

Cacao-

the worst sort of all, and are sold by the piece from one to two pavers per carpet.

CADET, a military term, denoting a young gentleman who chooses to carry arms in a marching regiment, as a private man. His views are to acquire some knowledge in the art of war, and to obtain a commission in the army. Cadet differs from volunteer, as the former takes pay, whereas the latter serves without any pay.

CADI, or **CADHI**, a judge of civil affairs in the Turkish empire.

It is generally taken for the judge of a town, judges of provinces being distinguished by the appellation of *mollas*.

In Biledulgerid, in Africa, the *cadi* decides in spiritual affairs.

CADILESCHER, a capital officer of justice, among the Turks, answering to a chief justice among us.

CADμία, in the natural history of the ancients, the name of two distinct substances, called native *cadmia*, and *facitious cadmia*. The native *cadmia* was only one of the copper ores; the *facitious cadmia* was a recement of copper, produced in the copper works.

Among the modern writers, it is not unusual to confound these substances with *tutty*. See the article **TUTTY**.

CADUCEUS, in antiquity, Mercury's rod, or sceptre, being a wand entwined by two serpents, borne by that deity, as the ensign of his quality and office, given him, according to the fable, by Apollo, for his seven-stringed harp.

CÆCILIA, in zoology, the name of a genus of serpents, the characters of which are these: the body is naked, with wrinkled sides; the upper lip is prominent beyond the rest of the mouth, and has two tentacula; but no tail.

Of this genus, authors enumerate several species, distinguished by the number of their rugæ or wrinkles.

CÆCUM, or **COECUM**, in anatomy, the blind gut, or first of the thick intestines. Of the three large intestines, called, from their size, *intestina crassa*, the first is the *cæcum*, situated at the right os ileum; it resembles a bag, and has a vermiform or worm-like appendage fixed to it. It begins at the termination of the ileum, and terminates in the bottom of the bag, or *feculus*, which it forms: its length is no more than three or four fingers breadth. In the appendage, or opening into the side of the *cæcum*, there are some glands, which, together with its erect situation, seems to shew that some fluid is secreted there. In hens, this is double; as also in many other fowls. In fishes, there are frequently a vast number of them; and in some species not less than four hundred. In man it is, at the utmost, single, and is often wanting.

CÆMENT. See **CEMENT**.

CÆMENTATION. See **CEMENTATION**.

CÆSALPINA, a decadrious tree, which produces very slender branches, armed with recurrent thorns; the leaves are winged, branching out into many divisions, each being furnished with small oval lobes, indented at the top, and placed opposite; the foot-stalks of the flowers come out from the side of the branch, and are terminated by a loose pyramidal spike of white flowers; each of these have a quinquefid cup, which contains five ringent petals: the fruit is an oblong, acuminate, unilocular cell, inclosing several compressed oval seeds. This tree affords the *brassiletto* wood, so called, which is much used in dying; it grows naturally in the warmest parts of America, from whence the wood is imported for the dyers; but the demand has been so great of late years, that in the British colonies the biggest tree scarce exceeds eight inches in diameter, and fifteen feet in height.

CÆSAR, in Roman antiquity, a title borne by all the emperors, from Julius Cæsar to the destruction of the empire. It was also used as a title of distinction, for the intended or presumptive heir of the empire, as king of the Romans is now used for that of the German empire.

This title took its rise from the surname of the first emperor, C. Julius Cæsar, which, by a decree of the senate, all the succeeding emperors were to bear. Under his successor, the appellation of Augustus being appropriated to the emperors, in compliment to that prince, the title of Cæsar being given to the second person in the empire, though still it continued to be given to the first; and hence the difference betwixt Cæsar used simply, and Cæsar with the addition of Imperator Augustus.

CÆSARIAN SECTION, in midwifery, a surgical operation, by which the fœtus is delivered from the womb of its mother, when it cannot be done in the natural way.

There are chiefly three different cases in which this operation is practicable; the first is, when the mother is dead, either in the birth, or by some accident, while the fœtus is reasonably supposed to be yet surviving in the womb: the second is, when the mother is living, and the fœtus dead, but incapable of being extracted or expelled by the natural passages: the third and last is, when the mother and fœtus are both living, but the latter is incapable of being brought into the world through the natural passages.

In the first case, this operation should be performed, not only as soon as possible, but even before the circulation in the mother is stopped, because the fœtus cannot long survive: then the abdomen must be laid open, by a crucial incision, as in common dissections, or by making a longitudinal incision on one side; and if the fœtus should have fallen into the cavity of the abdomen, from a rupture of the uterus, &c. it should be taken out immediately; but

if

if it remains concealed in the womb, that body should be cautiously opened, and the foetus extracted.

In the second case, the surgeon must make a longitudinal incision on the outside of the rectus muscle, between the navel and the angle of the os ilium, and thereby extract the foetus. If the foetus is contained in the Fallopian tube, or in the ovary, those parts are to be opened, and the foetus, with its placenta, then removed: but if the foetus is concealed in the uterus, this is also to be opened, by a longitudinal incision, sufficient to give a passage to the foetus, and its appendages.

In the third and last case, when the birth is prevented by a callosity of the vagina, or something amiss in the mouth of the uterus, a division and dilatation of these parts is preferable to the Cæsarian section, as less dangerous; and the same may be said when the vagina is obstructed by the hymen, or some other preternatural membrane: but when the callosity of the vagina is so large and hard, as to render the birth that way impracticable, if it was to be divided, there is no other means left but the Cæsarian section. If a rupture of the uterus should be made in the agonies of labour, so as to let out the foetus into the cavity of the abdomen, in this case it will be necessary to make an incision in that part made most prominent by the foetus, which should be extracted, as before.

CÆSTUS, in antiquity, a large gauntlet made of raw hide, which the wrestlers made use of when they fought at the public games.

This was a kind of leathern strap, strengthened with lead, or plates of iron, which encompassed the hand, the wrist, and a part of the arm, as well to defend these parts as to enforce their blows.

CÆSTUS, or **CÆSTUM**, was also a kind of girdle made of wool, which the husband untied for his spouse the first day of marriage, before they went to bed.

This relates to Venus's girdle, which Juno borrowed of her, to entice Jupiter to love her. See the article **CÆSTUS**.

CÆSURA, in the ancient poetry, is when, in the scanning of a verse, a word is divided, so as one part seems cut off, and goes to a different foot from the rest; as

Menti | ri no | li, nun | quam men | dacia | profunt.
Where the syllables *ri, li, quam,* and *men,* are cæsuras.

CÆSURA more properly denotes a certain and agreeable division in the words between the feet of a verse, whereby the last syllable of a word becomes the first of a foot; as in

Arma virumque cævo, trojæ qui primus ab aris.
Where the syllables *no* and *ææ* are cæsuras.

CÆSURA, in the modern poetry, denotes a rest,

or pause, towards the middle of an Alexandrine verse, by which the voice and pronunciation are aided, and the verse, as it were, divided into two hemistichs.

In Alexandrine verse of twelve or thirteen syllables, the cæsura must always be on the sixth; in those of ten, on the fourth; and in those of twelve, on the sixth: verses of eight syllables must not have any cæsura.

CÆTERIS PARIBUS, a Latin term, often used by mathematical and physical writers; the words literally signifying the rest, or the other things, being alike, or equal. Thus we say, the heavier the bullet, *cæteris paribus*, the greater the range; that is, by how much the bullet is heavier, if the length and diameter of the piece, and the quantity and strength of the powder be the same, by so much will the utmost range or distance of a piece of ordnance be greater.

Thus also, in a physical way, we say, the velocity and quantity of the blood, circulating, in a given time, through any section of an artery, will, *cæteris paribus*, be according to its diameter, and distance from the heart.

CAFFA, in commerce, painted cotton cloths manufactured in the East-Indies, and sold at Bengal.

CAG, or **KEG**, of surgeon, &c. a barrel or vessel that contains from four to five gallons.

CAHYS, a dry measure for corn, used in some parts of Spain, particularly at Seville and at Cadiz. It is near a bushel of our measure.

CAIMACAN, or **CAIMACAM**, in the Turkish affairs, a dignity in the Ottoman empire, answering to lieutenant, or rather deputy, among us.

There are usually two caimacans, one residing at Constantinople, as governor thereof; the other attending the grand vizir, in quality of his lieutenant, secretary of state, and first minister of his council; and gives audience to ambassadors. Sometimes there is a third caimacan, who attends the sultan; whom he acquaints with any public disturbances, and receives his orders concerning them.

CAINIANS, or **CAINITES**, in church history, Christian heretics, that sprung up about the year 130, and took their name from Cain, whom they looked upon as their head and father: they said that he was formed by a celestial and Almighty power, and that Abel was made but by a weak one.

This sect adopted all that was impure in the heresy of the Gnostics, and other heretics of those times; they acknowledged a power superior to that of the Creator; the former they called wisdom; the latter inferior virtue: they had a particular veneration for Korah, Abiram, Elshu, Lot, the Sodomites, and especially Judas, because his treachery occasioned the death of Jesus Christ: they even made use of a gospel, which bore that false apostle's name.

CAISSON,

CAISSON, in the military art, a wooden chest, into which several bombs are put, and sometimes only filled with gunpowder: this is buried under some work, whereof the enemy intends to possess themselves; and when they are masters of it, it is fired, in order to blow them up.

CAISSON is also used for a wooden frame, or chest, used in laying the foundations of the piers of a bridge.

CALABA, Indian mastich-tree, in botany, a genus of trees, whose characters are: it has a roseaceous flower, consisting of several petals, which are placed in a circular order; from whose flower-cup arises the pointal, which afterwards becomes a spherical fleshy fruit, including a nut of the same form.

This tree grows to a great magnitude in the warm parts of America, where it is a native. From the trunk and branches there issue out a clear gum, somewhat like the mastich, from whence it received its name; the gum being used in those countries as mastich.

At present this tree is pretty rare in England, it being so tender as not to bear the open air: so that it must be preserved in stoves, with the most tender exotic plants. It is propagated by the nuts, which are frequently brought from America; these should be planted in small pots, filled with fresh light earth, and plunged into an hot-bed of tanners bark, observing to water the pots frequently, to forward the vegetation of the nuts, which, having hard shells, are pretty long before they break their covers, unless they have a good share of heat and moisture. When the plants are come up about two inches high, they should be carefully transplanted, each into a separate small pot, filled with fresh light earth, and plunged into a moderate hot-bed of tanners bark, observing to water and shade them till they have taken new root; after which time they should have air admitted to them, in proportion to the heat of the weather, and the bed in which they are placed; and they must be frequently watered in warm weather. In this bed they may remain during the summer-season; but at Michaelmas they should be removed into the bark-stove, and placed in a warm situation. During the winter-season these plants will require water pretty often; but it should not be given to them in large quantities, especially in cold weather, lest it rot the fibres of their roots. As the plants advance, they must be shifted into larger pots, and treated in the same manner as the coffee-tree. See the article **COFFEE-TREE**.

With this management the plant will thrive very well; and as the leaves of this plant are long, strong, and of a shining green colour, they make a pretty appearance in the stove, with other tender exotic plants. *Miller's Gard. Dict.*

CALABASH, in botany, a species of melopepo, or cucurbita. See **CUCURBITA**.

CALABASH-Tree, the same with the crescentia of Linnæus.

CALADE, in the manege, the descent or sloping declivity of a rising manege ground, being a small eminence upon which we ride down a horse several times, putting him to a short gallop, with his fore hams in the air, to make him learn to ply or bend his haunches, and form his stop upon the aids of the calves of the legs, the stay of the bridle, and the cavesson, seasonably given.

CALAMANCO, a sort of woollen stuff manufactured in England and in Brabant. It has a fine gloss, and is chequered in the warp, whence the checks appear only on the right side. Some calamancos are quite plain, others have broad stripes adorned with flowers; some with plain broad stripes, some with narrow stripes, and others watered.

CALAMBA, or **CALAMBAC-WOOD**, the best kind of lignum-aloes.

CALAMIFEROUS, among botanists, the same with culmiferous. See the article **CULMIFEROUS**.

CALAMINARIS, or **LAPIS CALAMINARIS**, in natural history, a mineral substance, of a greyish, brownish, yellowish, or pale reddish colour, and sometimes of all these colours variously mixed; considerably heavy, and moderately hard, but never sufficiently so as to strike fire with steel; when mixed with powdered charcoal, changing copper, by fusion, into a yellow metal called brass. It is found plentifully in England, Germany, and other countries; either in distinct mines, or intermingled with the ores of lead or other metals.

CALAMINT, *Calamintha*, in botany, a distinct genus of plants, with square stalks; the leaves set in pairs; and the flowers on branched pedicles, whereof two issue from one joint in the bosoms of the leaves: the upper lip of the flower is divided into two segments, the lower lip into three. It is perennial, and flowers in June and July. There are three species of this plant used in medicine; namely,

1. Calamint, with reclining stalks; small irregularly oval leaves, very slightly indented, without pedicles; and the flower-stalks longer than the leaves. This species grows wild in dry grounds, and by the sides of fields.

It has a strong aromatic smell, approaching to that of penny-royal; and a moderately pungent taste, somewhat like that of spearmint, but warmer. In virtue, it appears to be nearly similar to a mixture of those herbs: infusions of the leaves are drank as tea, in weaknesses of the stomach, flatulent cholics, and uterine obstructions.

Water extracts by infusion nearly all the virtues of the calamint, and carries off, in evaporation, the whole of its specific flavour. In distillation with water, there separates from the aqueous fluid a considerable quantity of essential oil, of a very pungent taste, and smelling strongly of the herb. The remain-

remaining decoction, thus divested of the aromatic part of the plant, is unpleasantly roughish, bitterish, and mucilaginous.

Rectified spirit extracts the virtues of the calamin more perfectly than water, and gains from it a deep green tincture. On gently distilling the filtered liquor, a part of the flavour of the herb rises with the spirit, and a part remains behind in the inspissated extract. Spirit manifestly brings over more from this plant than from spearmint, and less than from penny-royal; its active matter being more volatile than that of the one, and less so than that of the other.

2. Common calamin, with upright stalks; larger, short, serrated, pointed leaves, set on pedicles; and the flower-stalks of the length of the leaves. It is found wild about the sides of highways, but is less common in this country than the other.

The leaves of this species are in taste weaker than those of the preceding. Their smell is strong, not like that of penny-royal, but rather approaching to that of the wild mints, though more agreeable. The essential oils of the two plants differ in flavour as the herbs themselves: in the spirituous extracts the difference is less considerable. They are supposed to agree in virtue, and have been used indiscriminately; the shops being generally supplied with the species which is most easily procurable.

3. Mountain calamin, with larger leaves and flowers than the two preceding, but smaller stalks; the leaves set on pedicles, pointed, acutely and deeply serrated like those of nettles; the flower-stalks shorter than the leaves, and of the length of the flowers themselves. It is a native of the southern parts of Europe, and raised with us in gardens.

This species has a moderately pungent taste, and a more agreeable aromatic smell than either of the other calamins. It appears to be the most eligible of the three as a stomachic.

CALAMUS, in botany, a genus of hexandrious plants, producing apetalous flowers, which are composed each of an hexaphyllous persistent cup; in which is inserted six capillary filaments topped with round antheræ; the fruit is a globose membranaceous pericarpium of one cell, which contains a round fleshy seed.

CALAMUS AROMATICUS, or ACORUS VERUS, in botany, the sweet-smelling flag, a plant which grows in marshy places in several parts of Europe. The leaves, which arise immediately from the root, are like those of the iris; they are sharp at the point, of a fine smooth, green colour, and about a quarter of an inch broad. The flowers are small, disposed in a compact spike, and cover the receptacle of fructification; each of these have a cylindrical spadix, in which is inserted six obtuse petals, with six crassifuscular filaments. The germen is gibbous and longish, without a style; but the stigma is

a prominent point. The fruit is a short triangular obtuse capsule of three cells, which contains a number of ovato-oblong seeds. The root of this plant is used in medicine, and is oblong, geniculated, and a little compressed. When fresh, it is of a whitish green colour, but afterwards turns of a reddish yellow; it is white and spongy within, easy to break, and of a strong fragrant smell, with a sharp bitterish taste: it abounds with a volatile essential oil; it is said to be good to strengthen the stomach, dissolving wind; the Indians use it in their sauces, and esteem it as a diuretic: the fume of it burnt with turpentine is recommended for diseases of the breast; and the Indian women, according to some, use it as an uterine and cephalic.

CALAMUS-SCRIPTORIUS, in antiquity, a reed or rush to write with.

The ancients made use of styles to write on tables covered with wax; and of reed, or rush, to write on parchment, or Egyptian paper.

CALAMUS-SCRIPTORIUS, in anatomy, a dilatation of the fourth ventricle of the brain; so called from its figure, which resembles that of a goose-quill.

CALANDRA, in ornithology, a name by which some call the great lark, without any crest.

CALASH, or CALESH, a light and very low kind of chariot, used chiefly for taking the air in parks and gardens.

Knights of CALATRAVA, a military order in Spain, instituted under Sancho III. king of Castile, upon the following occasion. When that prince took the strong fort of Calatrava from the Moors of Andalusia, he gave it to the Templars, who wanting courage to defend it, returned it him again. Then Don Raymond, of the order of the Cistercians, accompanied with several persons of quality, made an offer to defend the place, which the king thereupon delivered up to them, and instituted that order. It increased so much under the reign of Alphonfus, that the knights desired they might have a grand master, which was granted. Ferdinand and Isabella afterwards, with the consent of pope Innocent VIII. re-united the grand mastership of Calatrava to the Spanish crown; so that the kings of Spain are now become perpetual administrators thereof.

The knights of Calatrava bear a cross gules, fleurdiselé with green, &c. their rule and habit was originally that of the Cistercians.

CALCANEUM, or OS CALCIS, in anatomy, the bone lying under the astragalus, to which, and the os cuboides, it is articulated. Its apophysis behind serves to prevent our falling backward, and on its posterior surface is inserted the tendo achillis; in its interior side there is an excavation, intended to give safe passage to the vessels running to the metatarsus and toes.

CALCAR, in anatomy, the same with **calcaneum**. See the article **CALCANEUM**.

CALCAR, in glass-making, a sort of oven, or reverberatory furnace, in which, being well heated, the crystal frit, or bollito, is made.

CALCARIOUS, in general, denotes something belonging to, or partaking of, the nature of calx. See the article **CALX**.

CALCARIUS LAPIS, in natural history, the same with lime-stone. See **LIME**.

CALCEDON, among jewellers, denotes a flaw or foul vein, like chalcedony, found in some precious stones.

CALCEDONY, or **CHALCEDONY**, in the history of precious stones. See the article **CHALCEDONY**.

CALCINATION, in chemistry, the separating, by means of heat or fire, the more fixed from the volatile parts of any compound body.

CALCULATION, the act of computing several sums, by adding, subtracting, multiplying, or dividing. See the articles **ARITHMETIC**, **ADDITION**, &c.

CALCULATION is more particularly used to signify the computations in astronomy and geometry, for making tables of logarithms, ephemerides, finding the time of eclipses, &c. For the calculation of clock and watch-work, see **CLOCK** and **WATCH-WORK**.

CALCULUS, in natural history, properly denotes a little stone or pebble. See the article **PEBBLE**.

CALCULUS, or **CALCULUS-HUMANUS**, in medicine, the stone in the bladder or kidneys. See the article **STONE**.

CALCULUS Differentialis, is the arithmetic of infinitely small differences between variable quantities, which in England we call **fluxions**. The calculus differentialis therefore, and **fluxions**, are the same thing under different names; the latter given by Sir Isaac Newton, and the former by Mr. Leibnitz, who disputes with Sir Isaac the honour of the discovery.

Mr. Leibnitz, about 1676, by most foreigners is allowed to have first invented this doctrine of infinitely small quantities, who called it the *calculus differentialis*; but it is plain, from Sir Isaac's papers, that Sir Isaac was the first inventor of it, who being too free in communicating it to Mr. Leibnitz, he stole it from him; and that the suspicion might be the less, he invented different words and notes from those in Sir Isaac's method; for instead of putting the fluxion of x thus, $\dot{x}$, he puts it thus, dx ; and for y , dy , instead of y ; and these are used by almost all foreigners.

Yet even James Bernoulli, in the Leipstick acts for January 1691, acknowledges, that our famous Dr. Barrow (before Sir Isaac Newton; or M. Leibnitz either) had given some specimens of this method above ten years before that date, in his geometrical lectures, and of which all his apparatus of

propositions there contained are so many examples.

He also acknowledges that Mr. Leibnitz's method of *calculus differentialis*, is founded on Dr. Barrow's, and differs from it only in some notes and compendious abridgments. See **FLUXIONS**.

CALCULUS Exponentialis, among mathematicians, a method of differencing exponential quantities, and summing up the differentials of the same. By an exponential quantity is meant a power, the exponent of which is variable; as y^2 , e^x . In order to difference an exponential quantity, nothing more is required than to reduce the exponential quantities to logarithmic ones, upon which the differencing is managed in the same manner as logarithmic ones.

CALCULUS Integralis, is the method of finding, from a differential quantity given, the quantity from whose differencing the differential results. But in England we understand the method of finding the proper flowing quantity of any given fluxion to be the *calculus integralis*, and is the reverse of the calculus differentialis, which in England is to find the fluxion from the flowing quantity.

CALCULUS Specialis, or **Literalis**, the same as algebra. See **ALGEBRA**.

CALE, or **KALE**. See **CABBAGE**.

Sea CALE. See **CRAMBE**.

CALEA, in botany, a genus of syngenesious plants, whose flower is uniform and funnel-shaped, cut at the extremity into five parts, and contains five very short capillary filaments, topped with tubulose cylindrical antheræ; it is destitute of a pericarpium, but the calyx contains a single oblong seed topped with down.

CALEFACTION, the production of heat in a body from the action of fire, or that impulse impressed by a hot body upon other bodies about it. This word is used in pharmacy, by way of distinction from coction, which implies boiling; whereas calefaction is only heating a thing.

CALENDAR, or **ALMANACK**, is a political distribution of time, accommodated to the uses of life, and taken from the motions of the heavenly bodies. Of this kind are those annual books, wherein the days of the month, the festivals, the sign the sun is in, the sun's rising and setting, the changes of the moon, &c. are exhibited, which we also call **almanacks**. But the word **calendar** seems to come from the word *calendæ*, which amongst the Romans signifies the first days of every month.

The first calendar among the Romans was constructed by Romulus, who, being ignorant of the science of astronomy, supposed the sun to make its annual revolution in three hundred and four days, and therefore divided the year into ten months only, beginning on the first day of March. But Numa Pompilius, who added two months more, viz. January and February, placed them before March. His year consisted of three hundred and sixty-five days.

days. This was afterwards improved by Julius Cæsar, with the help of Sosigenes, a celebrated astronomer of those times, who found that the dispensation of time in the calendar could never be settled on any sure footing, without having regard to the annual course of the sun. Accordingly he observed the sun's annual revolution to be performed in three hundred and sixty-five days, six hours; therefore he reduced the year to the same number of days, which was retained in most Protestant countries, and in our nation till the year 1752. This correction, or Julian calendar, disposes the year into quadriennial periods, whereof the first three years, which were called common, consisted of three hundred and sixty-five days, and the fourth, called Bissextile, of three hundred and sixty-six, by reason of the six hours, which in four years make a day, or somewhat less; for in one hundred and thirty-four years an intercalary day is to be retrenched. On this account it was that pope Gregory XIII. with the advice of Clavius and Caiconius, appointed that the hundredth year of each century should have no Bissextile, excepting each fourth century: that is, a subtraction of three Bissextile days is made every four centuries, by reason of the eleven minutes wanting of the six hours, whereof the Bissextile consists. See BISSEXTILE.

Julian Christian CALENDAR, is that wherein the days of the week are determined by the letters A, B, C, D, E, F, G; by means of the solar cycle, and the new and full moons, especially the Paschal full moon, with the feast of Easter, and the other moveable feasts depending thereon, by means of golden numbers rightly disposed through the Julian year. See GOLDEN NUMBER.

Gregorian CALENDAR, that which, by means of epacts rightly disposed through the several months, determines the new and full moons, and the time of Easter, with the moveable feasts depending thereon in the Gregorian year. See EPACT.

Reformed, or corrected CALENDAR, is that which, setting aside golden number, epacts, and dominical letters, determines the equinox with the Paschal full moon, and the moveable feasts depending thereon, by astronomical computations, according to the Rudolphine tables, or any other tables that are more correct. This calendar was introduced among the Protestant states of Germany in the year 1700, when eleven days were at once thrown out of the month of February, by which the corrected style agrees with the Gregorian.

Astronomical CALENDAR, an instrument engraved upon copper plates, printed on paper, and pasted on board, with a brass slider, which carries a hair, and shews by inspection the sun's meridian altitude, right ascension, declination, rising, setting, amplitude, &c. to as great exactness as our common globes. For the construction of calendar or almanack, see EPHEMERIDES.

CALENDER, in mechanics, a machine used in manufactories, to press certain woollen and silken stuffs, and linens, to make them smooth, even, and glossy, or to give them waves, or water them, as may be seen in mohairs and tabbies. This instrument is composed of two thick cylinders or rollers of very hard and polished wood, round which the stuffs to be calendered are wound: these rollers are placed crosswise, between two very thick boards; the lower serving as a fixed base, and the upper moveable by means of a thick screw, with a rope fastened to a spindle, which makes its axis: the uppermost board is loaded with large stones cemented together, weighing twenty thousand pounds or more. It is this weight that gives the polish, and makes the waves of the stuffs about the roller, by means of a shallow indenture, or engraving cut in it. At Paris there is an extraordinary machine of this kind, called the royal calender, made by order of Mr. Colbert; the lower table or base of which is made of a block of smooth marble, and the upper lined at bottom with a plate of smooth polished copper.

CALENDS, *Calendæ*, in Roman chronology, is what the Romans called the first days of every month, from the Greek word *καλειν*, or *calco*, to call; because, anciently counting their months by the motion of the moon, there was a priest appointed to observe the time of the new moon; who, having seen it, gave notice to the president over the sacrifices, and he called the people together, and declared to them how they must reckon the days until the nones, pronouncing the word *calco* five times, if the nones did happen on the fifth day; or seven times, if they happened on the seventh day of the month. This is the account given by Varro: but others derive the appellation hence; that the people being convened on this day, the pontifex called or proclaimed the several feasts or holy-days in the month, a custom which continued no longer than the year of Rome 450, when C. Flavius, the curule edile, ordered the fasti, or calendar, to be set up in public places, that every body might know the difference of times and the return of the festivals. The Roman method of reckoning the days of their months is backwards, or in retrograde order, as is expressed in the following lines:

*Prima dies mensis cujusque est dicta calendæ:
Sex Maius, nonas, Julius, October, & Mars;
Quatuor at reliqui: habet idus quilibet octo;
Inde dies reliquos omnes dic esse calendæ;
Quas retro numerans, dice a mense sequente.*

Hence to find the day of our month answering to that of the calends:

To the number of days in the preceding month add two, and from this sum subtracting the number of calends given, and the remainder will be the

day

day of our month : thus the fourth of the calends of June is found to answer to the twenty-ninth of May ; and so in other cases.

CALENDULA, marygold, in botany, a genus of plants producing compound radiated flowers. There are divers species of this genus ; the common marygold has a root divided into many thick fibres or branches, the stalks are slender, a little angular, hairy, and clammy to the touch. It is divided into many branches, and furnished with oblong leaves, joined close to the stalk, widening from thence to the extremity, and of a light green colour. The flowers grow on the extremities of the branches, and are of a radiated orange colour ; each of these consist of hermaphrodite and female florets, included in a single envelopment : the hermaphrodite are tubulose, and semiquinifid ; and the female florets, which compose the rays, are long, ligulated, and cut in three segments at the extremity : there are no central seed in the disk ; those of the periphery are sometimes solitary, and are large, oblong, membranaceous, and cordated. This plant is annual, common in gardens, propagates itself by seeds, and flowers from May till autumn. The flowers of this plant are said to be aperient and dissolvent, and reckoned good in uterine obstructions, and icteric disorders ; and, infused in wine, they will open a slight obstruction of the liver, and cure a suppression of the menses. To this genus Linnæus has added the *caltha*, *dimorphotheca*, and *cardispermum* of other authors.

CALENTURE, *Calentura*, in medicine, a feverish disorder incident to sailors in hot climates ; the principal symptom of which is, their imagining the sea to be green fields : hence, attempting to walk abroad in these imaginary places of delight, they are frequently lost.

Vomiting, bleeding, a spare diet, and the neutral salts, are recommended in this disorder : a single vomit commonly removing the delirium, and the cooling medicines completing the cure.

CALF, *Vitulus*, in zoology, the young of the ox kind.

Among sportsmen, the term calf is used for a hart or hind of the first year. The same term is also used for the young of the whale.

There are two ways of breeding calves ; one, when they are allowed to suck their dams all the year round, chiefly used in countries where pasture is cheap ; and the other, when being taken from their dams after sucking a fortnight, they are taught to drink milk, or milk and water, out of a tub. The former, however, of these methods is allowed to make the best cattle.

CALF'S-SNOUT, in botany. See **ANTIRRHINUM**.

CALIBER, or **CALIPER**, properly denotes the diameter of any body : thus we say, two columns of the same caliber, the caliber of the bore of a

gun, the caliber of a bullet, &c. See **CANNON**, &c.

CALIBER-COMPASSES, the name of an instrument, made either of wood, iron, steel, or brass : that used for measuring bullets consists of two branches, bending inwards, with a tongue fixed to one of them, and the other graduated in such a manner, that if the bullet be compressed by the ends of the two branches, and the tongue be applied to the graduated branch, it will shew the weight of the bullet.

CALIBER also signifies an instrument used by carpenters, joiners, and bricklayers, to see whether their work be well squared.

CALIDUCT, in antiquity, a kind of pipes, or canals, disposed along the walls of houses and apartments, used, by the ancients, for conveying heat to several remote parts of the house, from one common furnace.

CALIPH, the supreme ecclesiastical dignity among the Saracens ; or, as it is otherwise defined, a sovereign dignity among the Mahometans, vested with absolute authority in all matters relating both to religion and policy.

It signifies in the Arabic successor, or vicar : the Saracen princes assumed this title as descendants from Mahomet, the caliphs bearing the same relation to Mahomet the popes pretend they do to Jesus Christ, or St. Peter. It is at this day one of the grand seignor's titles, as successor of Mahomet ; and of the sophi of Persia, as successor of Ali.

CALIXTINS, in church history, a sect of Christians in Bohemia and Moravia : the principal point in which they differed from the church, was the use of the chalice, or communicating in both kinds.

CALIXTINS is also a name given to those among the Lutherans who follow the sentiments of George Calixtus, a celebrated divine, who opposed the opinion of St. Augustine on predestination, grace, and free-will.

CALKING, in ship-building, the act of driving a quantity of oakum, *i. e.* old ropes untwisted and drawn asunder, into the seams of the planks, or into the intervals between the edges of the planks on a ship's decks or sides, to keep out the water. After the oakum is driven very hard into these seams, it is covered with hot-melted pitch, to prevent the water from rotting it.

Amongst the ancients, the first who made use of pitch in calking were the inhabitants of Phœacia, afterwards called *Corfica*. Wax and rosin appear to have been commonly used previous to that period ; and the Poles use a sort of clay for this purpose on their rivers at this day. See the article **Ship-BUILDING**.

CALKINS, the prominent parts at the extremities of a horse-shoe, bent downwards, and forged to a sort of point.

Calkins are apt to make horses trip : they also occasion

octation blymes, and ruin the back sinews. If fashioned in form of a hare's ear, and the horn of a horse's heel be pared a little low, they do little damage; whereas the great square calkins quite spoil the foot.

Calkins are either single or double; that is, at one end of the shoe, or at both: these last are deemed less hurtful, as the horse can tread more even.

CALICO, or CALLICO, a kind of linen manufacture, made of cotton, chiefly in the East-Indies. There is a great trade in the province of Bengal, in this commodity, which is transported in prodigious quantities in Persia, Turkey, Arabia, Muscovy, and all over Europe. Some of them are painted with flowers of various colours; and the women in the Indies make veils and scarfs of them, and, of some, coverlets for beds, and handkerchiefs. They make another sort of this manufacture, which they never dye, and hath a stripe of gold and silver quite through the piece; and at each end, from the breadth of one inch to twelve or fifteen, they fix a tissue of gold, silver, and silk, intermixed with flowers: both sides are alike. They make also other sorts of cotton cloths at Brampour, because there is no other province in all the Indies which has greater quantities of cotton.

At Seconge they are said to make the best sorts of calicoes; in all other parts the colours are neither so lively nor lasting, but wear out with often washing; whereas those made at Seconge grow the fairer the more you wash them. This is said to arise from a peculiar virtue of the river that runs by the city, when the rain falls; for the workmen, having made such prints upon their cottons as the foreign merchants give them, by several patterns, dip them into the river often, and that so fixes the colours, that they will always hold. There is also made at Seconge a sort of calico so fine, that when a person puts it on, his skin shall appear as plainly through it as if he was quite naked; but the merchants are not permitted to transport it; for the governor is obliged to send it all to the Great Mogul's seraglio, and the principal lords of the court, to make the sultaneſſes and noblemen's wives shifts, and garments for hot weather.

The city of Baroche also is very famous for trade, on account of the river, which has a peculiar quality to whiten their calicoes, and which are, therefore, brought from all parts of the mogul's territories thither for that end.

This manufacture is brought into this nation by the East-India company, which is re-exported by private merchants to other parts of Europe and America.

CALICO-Printing, the art of staining calicoes, &c. of various colours. See LINEN-Printing.

CALL, amongst sailors, a sort of whistle or pipe made of silver or brass, used by the boatswain and his mates, to summon the sailors to their duty,

and direct them in the various work of the ship, which they are taught to obey, by different strains of the call, as soldiers are directed by the drum, to march, retreat, charge, &c.

The principal articles which are commanded by this instrument, are, heaving round the capstern, veering away the cable, hoisting, lowering, belaying, &c. nor would such orders be heard without the call, on account of the bacchanalian clamour commonly made by sailors in such exercises, which would be impenetrable even to the boatswain's voice, although that indeed is more barbarous and dreadful than can be easily conceived.

We occasionally remarked, in the article BOATSWAIN, that his voice was extremely similar to the bray of an ass; but if any of our readers have heard the alternate roaring and whistling of that officer, they must naturally perceive that there is a most perfect sympathy between them; the latter of which seeming emulous, at every time he draws breath, when braying, to imitate the sound of the call. Indeed, if the Pythagorean system of transmigration were not exploded, and that our orthodoxy might therefore be questioned, we should not make the least scruple to believe, that the body of that sagacious beast is animated by the soul of a dead boatswain.

CALLA, the African arum, in botany, a gynandrious plant with a thick fleshy tuberose root, which is covered with a thin brown skin, with many fibres striking into the ground. The leaves are green and succulent, arrow-shaped, reflexed at the point, and are about eight or nine inches in length; these stand on footstalks about a foot long, and arise from the root in clusters. Between the leaves spring forth the footstalk of the flower, which is thick, smooth, of the same colour of the leaves rising above them, and terminated with a single flower, shaped like those of the arum; the hood or spathe being twisted at the bottom, but spreads open at the top, and is of a pure white colour. In the center of this is situated the spadix or club, which is of an herbaceous yellow colour, upon which the small flowers are placed, and so closely joined, as that the male and female parts are very difficult to be distinguished: when these decay, part of those which are situated at the top of the club, are succeeded by roundish fleshy berries compressed on two sides, each containing two or three obtuse seeds. This plant flowers in May, and the seeds are ripe in August; it propagates very fast by off-sets, and grows naturally at the Cape of Good Hope.

CALLICARPA, in botany, a bacciferous shrub which grows plentifully in the woods of Carolina; it rises from four to six feet high, sending out many branches from the side, which are woolly when young, and furnished with oval lanceolated leaves, placed opposite in pairs, and standing on pretty long footstalks;

footstalks; these are a little indented on their edges, their surface rough, and a little hoary. The flowers, which are of a deep purple colour, come out in whorles round the stalks, setting very close to the branches, at the footstalks of the leaves; each of these are small, tubulose, and monopetalous, cut into four obtuse segments at the top, which expand and contain four filiform filaments, topped with oblong yellow antheræ. In the center is placed a roundish germen, which afterwards becomes a smooth, round, succulent berry, which turns first to a bright red colour, but afterwards changes to a deep purple when ripe, and incloses four hard oblong compressed seeds. The leaves of this shrub is said to be used in dropical cases, with very good success.

CALLIGONUM, in botany, a genus of polyandrious plants, whose flower is apetalous, and consists of a pentaphyllous calix, the leaves of which are concave, roundish, and permanent; the filaments are small and numerous, topped with double antheræ; the fruit is an oval, compressed, striated, hairy pericarpium, with bifid tops, turning backwards, containing a single seed. In this genus Linneæus has classed the polygonoides of Tournefort.

CALLIMUS, καλλιμος, in natural history, the name used by the ancients for the loose substance found within the ætites, or eagle-stone. See the article **ÆTITES**.

CALLING the House, in the British parliament, is the calling over all the members names, every one answering to his own, and going out of the house, in the order in which he is called: this they do in order to discover whether there be any persons there not returned by the clerk of the crown; or if any member be absent without leave of the house.

CALLIPIC PERIOD, was an improvement of the cycle of Meton, of nineteen years, which Callippus, a famous Grecian astronomer, finding in reality to contain nineteen of Nabonassar's years, four days, and $\frac{2}{3}$, he, to avoid fractions, quadrupled the golden number, and by that means made a new cycle of seventy-six years; which time being expired, he supposed the lunations or changes of the moon would happen on the same day of the month, and hour of the day, that they were on seventy-six years before: but this has been demonstrated to be false, erring a whole day in five hundred and fifty-three years.

CALLISTEA, in Grecian antiquity, a Lesbian festival, wherein the women presented themselves in Juno's temple, and the prize was assigned to the fairest. There was another of these contentions at the festival of Ceres Eleusinia, among the Parthians, and another among the Eleans, where the most beautiful man was presented with a complete suit of armour, which he consecrated to Minerva, to whose temple he walked in procession, being

accompanied with his friends, who adorned him with ribbons, and crowned him with a garland of myrtle.

CALLOSUM CORPUS, in anatomy, a whitish hard substance, joining the two hemispheres of the brain, and appears in view when the two hemispheres are drawn back. See the article **BRAIN**.

In this part Lancisi, and several others, have supposed the soul particularly to reside.

CALLOUS, *Callosus*, something partaking of the nature of a callus.

CALLUS, or **CALLOSITY**, in a general sense, any cutaneous, corneous, or osseous hardness, whether natural or preternatural: but most frequently it means the callus generated about the edges of a fracture, provided by nature to preserve the fractured bones, or divided parts, in the situation in which they are replaced by the surgeon.

A callus, in this last sense, is a sort of jelly, or liquid viscous matter, that sweats out from the small arteries and bony fibres of the divided parts, and fills up the chinks, or cavities, between them. It first appears of a cartilaginous substance, but at length becomes quite bony, and joins the fractured part so firmly together, that the limb will often make greater resistance to any external violence with this part, than with those which were never broken.

But as the new flesh in wounds will often sprout up too fast, so will the callus in fractures, and by this means render the limb uneven and deformed: the only measure to prevent this luxuriance, is by making the bandage somewhat tighter than ordinary, and wetting it first with spirits of wine. When the callus is indurated, we have no medicine that will destroy it, or take it down: however, the emplastrum de ranis vigon. cum mercurio, tying a plate of lead over it, is prescribed for taking it down.

CALLUS is also a hard, dense, insensible knob, rising on the hands, feet, &c. by much friction and pressure against hard bodies.

CALM, in the marine language, that state of rest which appears in the air and sea when there is no wind stirring.

That tract of the Atlantic ocean, situated between the tropic of Cancer and the latitude of 26° north, or the space between the trade and variable winds, is frequently subject to calms of very long continuance; and hence it has justly acquired the name of the calm-latitude.

A long calm is often more fatal to a ship than the severest storm, if she is tight, and in good condition; as the provisions and water may be entirely consumed, where there may be no opportunity to obtain a fresh supply: at such a time the surface of the ocean is smooth and bright as a looking-glass.

CALOGERI, in church history, monks of the Greek church, divided into three degrees, the novices,

vices, called archari; the ordinary professed, called microchemi; and the more perfect, called mega-lochemi: they are likewise divided into cænobites, anachorets, and recluses. The cænobites are employed in reciting their office from midnight to sunset; they are obliged to make three genuflexions at the door of the choir; and returning, to bow to the right and to the left, to their brethren. The anachorets retire from the conversation of the world, and live in hermitages in the neighbourhood of the monasteries; they cultivate a little spot of ground, and never go out but on Sundays and holidays, to perform their devotions at the next monastery. As for the recluses, they shut themselves up in grottos and caverns, on the tops of mountains, which they never go out of, abandoning themselves entirely to providence: they live on the alms sent them by the neighbouring monasteries.

CALOMEL, in the materia medica, a name given to mercurius dulcis, sublimated six times: the preparation is done thus.

Take corrosive sublimate a pound, purified mercury nine ounces; add the quicksilver to the mercury, reduce to powder, and digest them together in a glass mattrass, in a gentle sand heat, frequently shaking the vessel, till the whole is united: when they are thus mixed, increase the heat, so as to sublimate the whole: take out the sublimate, and scrape off an acrid part that is found at the top of it; and if any globules of mercury appear, separate them also: let the sublimation be repeated six times. It is a gentle purgative, and a very noble attenuant. It is the greatest of all medicines against worms, and is now the general remedy in a gonorrhœa. The common method of giving it is in a bolus, over night, ten or twelve grains for a dose, and a purging draught the next morning, &c. Rubbed with an equal quantity of sulphur antimoniæ auratum, it is recommended as a powerful and safe alterative.

CALOPHYLLUM, a genus of polyandrious plants, whose flower consists of four roundish, concave, patent petals; the filaments are numerous, short, filiform, and topped with erect oblong anthers; the fruit is a large globose drupe, containing a round sub-acuminated nut. In this genus Linneus has classed the calaba of Plumier.

CALOTTE, a cap or coif, of hair, satin, or other stuff; an ecclesiastical ornament in most popish countries.

CALOTTE, in architecture, a round cavity or depression, in form of a cap or cup, lathed and plastered, used to diminish the rise or elevation of a moderate chapel, cabinet, alcove, &c. which, without such an expedient, would be too high for other pieces of the apartment.

CALQUING, or **CALKING**, a term used in painting, &c. where the backside of any thing is covered with a black or red colour, and the strokes

or lines traced through, on a waxed plate, wall, or other matter, by passing lightly over each stroke of the design with a point, which leaves an impression of the colour on the plate or wall.

CALTHA, marsh-marygold, in botany, a genus of polyandrious plants, the flower of which consists of five large, oval, plane, deciduous petals; the filaments are slender and numerous, shorter than the petals, and topped with obtuse erect anthers; in the center is placed several oblong compressed germen, which afterward becomes so many short, acuminate bicarinated capsules, containing a number of roundish seeds.

Marsh-marygolds grow upon moist boggy lands in many parts of England, a variety of which, with double flowers, is preserved in some gardens, and is propagated by parting the roots in autumn.

CALTHA is also the name by which Tournefort calls the calendula, or marygold.

CALTROPS. See the article **CHAUSSES-TRAPESES**, or **CROWS-FEET**.

CALTROPS, in botany. See the article **TRIBULUS**.

Water CALTROPS. See **TRAPA**.

CALVARIA, in anatomy, the hairy scalp or upper-part of the head, which, either by disease, or old age, grows bald first. See the articles **HEAD** and **CALVITIES**.

CALVARY, in heraldry, a cross so called, because it resembles the cross on which our Saviour suffered. It is always set upon steps.

CALVINISTS, in church history, those who follow the opinions of John Calvin, one of the principal reformers of the church in the sixteenth century, a person of great parts and industry, and of considerable learning; whose doctrine still subsists in its greatest purity at Geneva, where it was first broached, and from whence it was propagated. This is the prevailing religion of the United Provinces. In England it is confined among the dissenters; and, in Scotland, it subsists in its utmost rigour.

The Calvinists are great advocates for the absoluteness of God's decrees; and hold that election and reprobation depend on the mere will of God, without any regard to the merit or demerit of mankind; that he affords to the elect an irresistible grace, a faith that they cannot lose, which takes away the freedom of will, and necessitates all their actions to virtue.

The Calvinists believe that God fore-knew a determinate number, whom he pitched upon to be persons, in whom he would manifest his glory; and that, having thus fore-known them, he predestinated them to be holy, in order to which he gives them an irresistible grace, which makes it impossible for them to be otherwise.

CALVITIES, or **CALVITIUM**, in medicine, baldness,

haldness, or a want of hair, particularly on the sciniput, occasioned by the moisture of the head, which should feed it, being dried up, by some disease, old age, or the immoderate use of powder, &c. See the article *ALOPECIA*.

CALUMET, a symbol of peace among the Indians in the north of America. It is made of a red stone, like our marble; the head resembles our tobacco-pipes, but larger; and is fixed on a hollow reed, to hold it for smoking; they adorn it with fine wings of several colours, and is the calumet of the sun, to whom they present it, especially if they want fair weather, or rain. This pipe is a pass and safe-conduct amongst all the allies of the nation who has it given: in all embassies the ambassador carries it as an emblem of peace, and it always meets with a profound regard; for the savages are generally persuaded, that a great misfortune would befall them, if they violated the public faith of the calumet.

CALX, properly signifies lime, but it is also used by chemists and physicians for a fine powder remaining after the calcination, or corrosion of metals and other mineral substances. See *CALCINATION* and *LIME*.

CALYCANTHUS, in botany, a genus of icosandrious plants, whose flower is apetalous; but contain a monophyllous calyx; the filaments are numerous, and awl-shaped, topped with oblong, sulcated antheræ; the germina are numerous, and contains a number of caudated seeds. In this genus Linnæus has included the *bureria*, *butneria*, and *basteria* of other authors.

CALYCISTÆ, an appellation given by Linnæus to those botanists who have classed plants according to the different structure of the calyx, or cup of the flowers; such was Magnolius.

CALYPTRA, or veil, a term given by botanists to a peculiar kind of calyx; it is a thin membranaceous involucre, usually of a conic figure, and covers the stamina, and other parts of fructification: the capsules of most of the mosses have calyptræ.

CALYX, among botanists, signifies the cup of a flower; this is the termination of the cortex, or outer bark of plants, which, after accompanying the trunk or stem through all its branches, breaks out with the flower, and is present in the fructification; in this new form its chief use is to inclose and protect the other parts. The calyx has received different appellations, according to the circumstances with which it is attended, and on that account distinguished by several names, as perianthium, involucre, amentum, spatha, gluma, calyptra, and volva. See the articles *PERIANTHIUM*, &c.

That the calyx is a part of the flower, (though it often attends the fruit) is manifest from hence, that there is no instance of its coming out after the

plant has done flowering. Calyx is also often styled the empalement of a flower.

CAMÆA, in natural history, a genus of the semipellucid gems, approaching to the onyx structure, being composed of zones, and formed on a crystalline basis; but having their zones very broad and thick, and laid alternately on one another, with no common matter between; usually less transparent; and more debased with earth than the onyxes.

CAMAIEU, or **CAMEHUA**, in natural history, the same with *camæa*. See the preceding article.

CAMAIEU is also a term in painting; when there is only one colour, the lights and shades being of gold, or on a golden and azure ground; It is chiefly used to represent basso-relievos.

CAMALDULIANS, a religious order founded by St. Romauld, in a little plain on the Mount Appennine, called Camaldali, situated in the state of Florence.

CAMBERED-DECK, in the marine, the deck, or flooring of a ship, is said to be cambered, or to lie cambering, when it is higher in the middle of the ship, and droops towards the stem and stern, or the two ends; also when it lies irregular, being higher in one place than another, a circumstance which renders the ship very unfit for war.

CAMBLET, or **CAMLET**, a plain stuff, composed of a warp or woof, which is manufactured on a loom, with two treadles, as linens are.

There are camblets of several sorts, some of goats-hair, both in the warp and woof; others, in which the warp is of hair, and the woof half hair and half silk; others again, in which both the warp and the woof are of wool; and lastly, some, of which the warp is of wool and the woof of thread. Some are dyed in the thread, others are dyed in the piece, others are marked or mixed; some are striped, some waved or watered, and some figured.

CAMEL, *Camelus*, in zoology, a genus of quadrupeds, of the order of the pecora; distinguished from the rest by having no horns.

This genus comprehends the camel, properly so called, with two bunches on its back; the dromedary, or camel with a single bunch; the glama, or Peruvian camel, with a gibbose breast and even back; and the pacos, or camel with no gibbosity at all.

The camel is larger than the dromedary, and covered with a fine fur, shorter as well as softer than that of the ox kind; only about the branches there grow hairs nearly a foot long. It is a native of Asia, particularly of Bactria, and makes an excellent beast of burden.

CAMELEON, or **CHAMELEON**, in zoology. See the article *CHAMELEON*.

CAMELLIA, in botany, a genus of plants: the flower consists of five ovated petals, connected vertically

tically at the base; the fruit is a turbinate, lignose, and furrowed capsule; the seeds are numerous and small.

CAMELOPARDALIS, in zoology, a creature of the deer kind, otherwise called zurnapa. See the article ZURNAPA.

CAMELOPARDALIS, in astronomy, is a new constellation in the northern hemisphere, formed by Hevelius, consisting of thirty-two stars, first observed by him; but since his time many more have been observed, and their places settled. This constellation is situated between Cepheus, Cassiopeia, Perseus, the two Bears, and Draco. The right ascension, declination, with the variation, &c. to the year 1770, is exhibited in the following catalogue.

Order.	Magn.	Name.	Right Ascension	Distance from Nor. Pole.	Var. in Right Ascen.	Var. in Declination.
1	6		63.17.3	36.37.56	69.2	6.1

CAMERA OBSCURA, in optics, a machine, representing an artificial eye, wherein the images of objects are exhibited distinctly, and in their native colours, either invertedly, or erect.

The camera obscura, or dark chamber, is of two kinds. The one is no other than a convex lens fixed in a hole of a window-shutter, which lens, when no other light is permitted to enter the room, except what passes through it, will represent all the external objects, that are visible through that hole, upon a white paper held at the focal distance of the lens, painted in their proper colours; but the objects will be represented inverted, because the pencil of rays that flows from the object crosses in the middle of the glass. The other sort of camera obscura, is that which is called the portable one, and is of use in drawing landscapes, &c.

In Plate XXV. you have represented the different sorts of cameras.

Fig. 1. is of the first kind above-mentioned, where A B C D is the prospect of a house, trees, &c. E F a darkened room, or camera obscura, on one side is the picture G H, of the above view inverted, formed by a convex lens, fixed in a large cylindric pole, bored through the middle of a ball, commonly called the sky-optic-ball, which is easily moveable about its centre, within a hollow zone made of wood, and fastened to the window-shutter at V; this zone consists of two half zones screwed together in the middle after the ball was let in, and the concavity of the zone hinders the light from passing between it and the ball.

Fig. 2. is a portable camera obscura in the form

the Grecian camps, it may be observed, that the most valiant of the soldiers were placed at the extremities, the rest in the middle. Thus we learn from Homer, that Achilles and Ajax were posted at the ends of the camp before Troy, as bulwarks on each side of the princes.

The camps of the Romans were generally either of an exact square form, or else oblong; though this was often accommodated to the situation of the place. They were always fortified, and a very exact discipline maintained in them, in order to prevent surprizes from the enemy.

CAMP is also used by the Siamese, and some other nations in the East-Indies, as the name of the quarters which they assign to the foreigners who come to trade with them.

In these camps every nation forms, as it were, a particular town, where they carry on all their trade, not only keeping their warehouses and shops there, but also live in these camps with their whole families. The Europeans, however, are so far indulged, that at Siam, and almost every where else, they may live either in the cities or suburbs, as they shall judge most convenient.

Flying CAMP, the ground on which a flying army is encamped.

CAMP-DISEASES are chiefly a bilious fever, malignant fever, scurvy, fluxes, &c. See the articles FEVER and CAMPAIGN.

CAMP-HOSPITAL. See HOSPITAL.

CAMPAIGN, in the art of war, denotes the space of time that an army keeps the field, or is encamped, in opposition to quarters.

CAMPANIFORM, or CAMPANULATED, an appellation given to flowers resembling a bell; a characteristic, whereon Tournefort establishes one of his classes. See the article BOTANY.

The word is compounded of the Latin, *campana*, a bell, and *forma*, resemblance.

CAMPANULA, bell-flower, in botany, a genus of plants, the flower of which consists of a campanulated single petal; the base broad and impervious; the limb lightly divided into five broad, acute, petaloid segments. The nectarium is situated in the bottom of the corolla, and is formed of five acute connivent valves. The fruit is an angulated roundish capsule, with three or five cells, and having for many foramina in the sides, for letting out the seeds. The seeds are numerous and small, and the receptacle fixed and columnar.

CAMPEACHY-WOOD, *Campecia*, in botany, the same with the *hæmatoxylum* of Linnaeus, otherwise called logwood.

It is brought to us in large and thick blocks or logs, and is the heart only of the tree which produces it. It is very heavy, and remarkably hard. It is not easily cut, but it splits pretty readily in a longitudinal direction.

Campeachy-wood must be chosen in large and

thick pieces, sound, and of a deep red colour. It has been long known among the dyers; but it is only of late that it has been introduced into medicine. It is found to be an excellent astringent, and is given, in form of an extract, in diarrhoeas, with very great success.

CAMPHOR, in the materia medica, a body of a particular nature, being a mixed substance, dry, white, transparent and brittle, and of a very penetrating smell.

There are sundry Indian plants from which camphors are obtainable, but only two which afford any large quantity, and from which this commodity is commonly prepared, one growing in Sumatra and Borneo, the other in Japan, as particularly about Satsuma. The first is called by Breynius *camphorifera Sumatrana*, &c. the camphor-tree of Sumatra, with leaves like those of the clove-tree, but longer pointed, a large oblong fruit, and a very large cup, somewhat resembling a tulip: the latter, *camphorifera Japonica*, &c. the camphor-tree of Japan, with bay-like leaves, a small globular fruit, and a very short cup. The camphor of the Japan species is the only sort kept in the shops, the other being never brought into Europe. This tree is about the size of a large lime, the flowers are white, the fruit is a small berry. All the parts of it are impregnated with camphor, but the roots contain most: hence the roots are chiefly made use of for the preparation of this commodity; though, in want of sufficient quantities of these, the wood and leaves are mixed.

The camphor is extracted by distillation with water in large iron pots, on which are fixed earthen heads stuffed with straw; greatest part of the camphor concretes among the straw in its crystalline form, and a part likewise passes down into the receiver along with the water. It is said by some to be extracted by sublimation without water; but by such a process, it could not avoid receiving from the woody matter an empyreumatic smell, which it is never found to have. The rough camphor, as first distilled, looks much like the grey, small-crystallized East-Indian salt-petre, or like common bay-salt: in this state it is imported in canisters into Europe, particularly into Holland, and there purified or refined.

The refining of camphor was formerly one of the manufactures of Venice, the Venetians being then the only people in Europe who traded directly to the East-Indies: but that trade has long ago passed into other hands; the Venetians now import little or no camphor, and the art of refining it is known only to the Dutch. The English and French import some rough camphor, but send it to Amsterdam to be refined, having never been able to succeed in the process themselves.

Camphor, considered as a medicine, is a very warm-diaphoretic and antiseptic: it does not how-

ever heat the constitution so much as might be expected from its hot pungent taste. I have been assured by an eminent physician, that a single drop of oil of cinnamon, though generally containing a little expressed oil, beats more than ten grains of camphor, and an ounce of strong spirit of wine more than a whole dram. Camphor is employed likewise in fire-works, and in sundry other arts, particularly for varnishes. Camphorated varnishes excellently preserve both animal and vegetable bodies, and peculiarly resist worms and other insects. Camphor, in substance, also laid among clothes, preserves them from moths.

CAMPION, in botany, a name sometimes given to the lychnis. See the article **LYCHNIS**.

Viscous CAMPION. See **SILENE**.

CAMPUS, in antiquity, a space of ground in cities, left without any buildings, not unlike what we call fields or squares.

CAMPUS MAIL, in ancient customs, an anniversary assembly of our ancestors held on May-day, when they confederated together for defence of the kingdom against all its enemies.

CAMPUS MARTIUS, among the Romans, a field by the side of the Tyber, where the youth exercised themselves in warlike exercises. It was so called on account of a temple that stood on it, consecrated to the god Mars.

CANAL, *Canalis*, in hydrography, a kind of artificial river, made for the convenience of water-carriage.

CANALS are contrived for various purposes, some for forming a communication between one place and another; as the canals between Bruges and Ghent, or between Brussels and Antwerp; others for the ornament of a garden, or house of pleasure, as those of Versailles, Fontainebleau, or St. James's Park.

Egypt is full of canals, dug to receive and distribute the waters of the Nile at the time of its inundation: these however are dry the rest of the year, except the canal of Joseph, and four or five others, which may be ranked as considerable rivers.

CANALS of communication are artificial cuts, commonly furnished with locks and sluices, and sustained by banks or mounds, in order to make a quicker passage, and shorten the way between one place and another, by means of vessels.

Store of navigable canals and rivers is one of the marks of good policy in a country; in which respect Italy, the Netherlands, and France, but especially China, abound as much as England is defective.

In China indeed there is scarcely a town or village but what has the advantage of an arm of the sea, a navigable river, or a canal, by which means navigation is rendered so common, that there are almost as many people on the water as land: but in England we have only one remarkable canal, and that made by other people, and suffered to decay by ourselves; that is, the ancient canal from the

river Nen, a little below Peterborough, to the river Witham, three miles below Lincoln, called by the modern inhabitants *Caerdike*; which may be ranked amongst the monuments of the Roman grandeur, though almost filled up now. It was forty miles long; and, so far as appears from the ruins, must have been very broad and deep. Some authors take it for a Danish work. Morton will have it made under the emperor Domitian: urns and medals have been discovered on the banks of this canal, which seem to confirm that opinion.

The canal of Languedoc, called also the *canal of the two seas*, as serving to join the Mediterranean and Cantabrian seas, was first proposed under Francis I. but begun and finished under Louis XIV. By means of it a ready communication is made between the two fertile provinces of Guyenne and Languedoc: the canal is sixty-four leagues long, extended from Narbonne to Tholouse, and, receiving several little rivers in the way, supported at proper intervals with one hundred and four sluices. In some places it is conveyed over aqueducts and bridges of incredible height, built on purpose, which give passage underneath to considerable rivers. What is most extraordinary is, that in some places, for a mile together, a passage is dug out for it through the rock. The expence was thirteen millions of livres, of which the king contributed seven, and the province of Languedoc the rest.

The canals of Briere and Orleans are also of very great use for the same purposes.

The canal of Egypt, for a communication between the Nile and the Red Sea, was begun, according to Herodotus, by Necus, son of Psammeticus, who desisted from the attempt, on an answer from the oracle, after having lost six-score thousand men in the enterprize. It was resumed and completed by Darius, son of Hytaspes, or, according to Diodorus and Strabo, by Ptolemy Philadelphus; who relate, that Darius relinquished the work, on a representation made to him by unskilful engineers, that the Red Sea, being higher than the land of Egypt, would overwhelm and drown the whole country. It was wide enough for two galleys to sail abreast; its length was four days sailing. It seems to have been opened anew by the caliph Omar, in the year 635. Elmacin indeed says, that a new canal was then made for the conveyance of the corn of Egypt to Arabia; but this is more naturally understood of a removal of the ancient one; the navigation of which, towards the decline of the Roman empire, had been much neglected: there are some traces of it however still subsisting.

The great canal of China is one of the wonders of art, made about eight hundred years ago. It runs from north to south quite cross the empire, beginning at the city Canton. By it all kinds of foreign merchandize, entered at that city, are carried directly to Pekin, a distance of eight hundred and

twenty-five miles. Its breadth and depth are sufficient to carry barks of considerable burden, which are managed by sails and masts, as well as towed by hand. On this canal the emperor is said to employ ten thousand ships, abating one for a reason very particular. It passes through, or by, forty-one large cities; there are in it seventy-five vast locks and sluices to keep up the water, and pass the barks and ships, where the ground will not admit of a sufficient depth of channel, besides several thousand draw, and other bridges on it.

The Spaniards have several times had in view the digging a canal through the isthmus of Darien, from Panama to Nombre de Dios, to make a ready communication between the Atlantic and the South-sea, and thus afford a straight passage to China and the East-Indies.

CANAL of an aqueduct, is the part through which the water passes; which, in the ancient edifices of this kind, is lined with a coat of mastic of a peculiar composition.

CANAL, in anatomy, a duct or passage through which any of the juices flow: as, 1. The semi-circular canals, distinguished by the epithets of the largest, the middle one, and the least, in the labyrinth of the ear, opening by five orifices into the vestibule. 2. The canals of the auditory nerve, viz. the common and larger, in which there are little apertures into the labyrinth, and the proper, narrower, and longer, terminating partly by a little aperture in the cavity of the cranium, and partly in the aqueduct of Fallopius. 3. The canalis arteriosus, between the pulmonary artery and the aorta of a fœtus, which serves for a peculiar circulation in the fœtus. 4. The nasal canal. 5. The canalis femilunaris. And 6. The canalis venosus. See the article FOETUS, NOSE, &c.

CANAL of the Larmier, the hollowed platfond, or soffito of a cornice, which makes the pendent mouchette. See the articles LARMIER and SOFFITO.

CANAL of the Voluts, in the Ionic capital, the face of the circumvolutions inclosed by a listel.

CANALICULATE, or CANALICULEATED, something hollowed in the manner of a canal; thus we say a canaliculated leaf, a canaliculated stalk.

CANARY-BIRD, *Passer Canariensis*, the English name of the whitish *Irungilla*, with the wings and tail greenish.

Canary birds are natives of the Canary Islands, whence they have got their name; but the melody of their voice is so sweet, that there are few nations in Europe which do not keep them in cages, where they very readily breed.

CANARY-GRASS. See the article GRASS.

CAN-BUOY. See the article BUOY.

CANCER, the crab, in zoology; the name of a well-known shell-fish, of which there are a great many species; as the common large crab, the spider-

crab, the Molucca-crab, or king-crab, the little woolly-crab, the prickly long-armed crab, &c.

CANCER, in surgery, a roundish unequal hard livid tumour, generally seated in the glandulous parts of the body, and at length appearing with turgid veins, shooting out from it so as to resemble, as it is thought, the figure of the crab-fish, or, as others say, because, like that fish, when once it has got hold, it is scarce possible to drive it away.

Cancerous, or scirrhus tumours, often appear spontaneously without any evident cause, and seem peculiar to certain constitutions; at others, they may be accidental, or proceed from sharp corrosive, or other coagulated juices in the body, errors in the non-naturals, a stoppage of the necessary evacuations, contusions, stagnation, or coagulation of the milk in the breast, &c. The immediate cause of a cancer seems to be a too corrosive volatile salt, approaching to the nature of arsenic, formed by the stagnation of humours, &c. Stollerforth observes, that it has been frequently cured by mercury and salivation. Some take an ulcerous cancer to be nothing else but an infinite number of little worms, which devour the flesh by degrees. The cancer is allowed to be the most terrible evil that befalls the body; it is usually cured, while yet a small tumour of the bigness of a nut, or at most a small egg, by extirpation; when it seizes the breast, or is burst into an ulcer, amputation takes place. It begins without any pain, and appears at first like a chicory pea, but grows apace, and becomes very painful. The cancer arises principally on the lax and glandulous parts, as the breasts and emunctories: it is most frequent in women, especially such, says Stollerforth, as are barren, or live in celibacy. The reason of its appearing in the breasts, more than other parts, is, they being full of glands, with lymphatics and blood-vessels among them, the smallest contusion, compression, or puncture, extravasates those liquors, which grow by degrees acrimonious from the cancer. Hence the masters of the art say, that a cancer is that in the glands, which a caries is in the bones, and a gangrene in the fleshy part.

The cancer is, however, found in other soft spongy parts of the body; and there have been some found in the gums, belly, neck of the matrix, ureters, lips, nose, cheeks, abdomen, thighs, and even in the shoulders, as Stollerforth proves. A cancer arising on the leg is called a lupus; or in the face or nose, a noli me tangere. Cancers are divided, according to their several stages, into occult and open, or ulcerated: occult cancers are those not arrived at their state, or not yet burst; ulcerated cancers are known by their roughness and fulness of holes, through which oozes a filthy stinking glutinous matter, frequently yellowish; by their pungent pain, which resembles the pricking of pins; by their blackness, the swelling of the lips of the ulcer,

ulcer, and the veins about it, which are blackish, tumid, and varicose: sometimes the extremities of the blood-vessels are gnawed off, and the blood issues out. In a cancer of the breast, the adjacent flesh is sometimes so consumed, that one may see into the cavity of the thorax; it occasions a slow fever, a loathing, oftentimes faintings, sometimes a dropfy, and, lastly, death.

Some cancerous tumours are moveable, others fixed; some inflamed, others palish, and attended with pain, heat, tension, and pulsation. In their beginning they are sometimes no bigger than a pea, but often increase gradually to the size of a walnut, egg, &c. sometimes also their growth is sudden, and at others slow, so as to continue upon the increase many years together. When they ulcerate, the suppuration is generally partial, the matter they discharge seeming of an ill colour, and very fetid.

All cancers are dangerous, and seldom give way to the use of evacuating medicines, especially when they lie deep, or seem owing to a particular constitution of the patient. They also prove more difficult to cure, according to their size, the nature and office of the part they affect, the age of the patient, &c. Some occult cancers, particularly those which happen in the breasts of women, may remain harmless to the body for several years, and without ulcerating; though, upon any external injury, they may afterwards increase, break, and soon prove mortal. In this case, every thing that suddenly raises the velocity of the blood should be carefully avoided.

The learned Dr. Stork, of Vienna, has published two pieces on the virtues of cicuta, or hemlock, in the cure of cancers, and given many remarkable cases in which it was attended with success. Experiments of the same kind have also been made in England, some of which have succeeded, while others have totally failed of success: so that the virtues of the hemlock in curing this terrible disease are not yet properly established. See the article *CICUTA*.

CANCER, in astronomy, is one of the twelve signs of the zodiac, represented on the globe, in the form of a crab, as in Plate XXVI. It is the fourth sign, reckoning from the point Aries, and gives name to one of the quadrants of the ecliptic. According to Ptolemy it contains thirteen stars, Tycho Brahe fifteen, Bayer and Hevelius twenty-nine, but in the British Catalogue eighty-three.

The poets tell us, that this is the crab which bit Hercules by the heel while he was fighting with the serpent Hydra in the fen Lerna; for which service the crab was placed in heaven by Juno, who was the utter enemy of Hercules. It was not without a great deal of propriety, that the ancients represented this sign by the crab; for they first took notice that the sun gradually ascended above the equinoctial, till it arrived at this sign, from which it af-

terwards declined again, and descended as gradually, which retrograde motion they very pertinently represented by the side-long, or retrograde motion of a crab. For the places of the stars in this constellation, see the following catalogue.

CANCEROUS, something belonging to, or partaking of, the nature of a cancer. See the article **CANCER**.

CANDIDATE, a person who aspires to some public office.

CANDLE, a small taper of tallow, wax, or sperma ceti; the wick of which is commonly of several threads of cotton, spun and twisted together.

There are two sorts of tallow-candles; the one dipped, the other moulded: the former are the common candles; the latter are the invention of the Sieur le Brege, at Paris.

The method of making candles, in general, is this: after the tallow has been weighed, and mixed in the due proportions, it is cut into very small pieces, that it may melt the sooner; for the tallow in lumps, as it comes from the butchers, would be

in danger of burning, or turning black, if it were left too long over the fire. Being perfectly melted and skimmed, they pour a certain quantity of water into it, proportionable to the quantity of tallow. This serves to precipitate to the bottom of the vessel the impurities of the tallow which may have escaped the skimmer. No water, however, must be thrown into the tallow designed for the three first dippings; because the wick, being still quite dry, would imbibe the water, which makes the candles crackle in burning, and renders them of bad use. The tallow, thus melted, is poured into a tub, through a coarse sieve of horse-hair, to purify it still more, and may be used after having stood three hours. It will continue fit for use twenty-four hours in summer, and fifteen in winter.

The wicks are made of spun cotton, which the tallow-chandlers buy in skains, and which they wind up into bottoms or clues: whence they are cut out with an instrument contrived, on purpose, into pieces of the length of the candle required; then put on the sticks or broches, or else placed in the moulds, as the candles are intended to be either dipped or moulded. Wax-candles are made of a cotton or flaxen wick, slightly twisted, and covered with white or yellow wax. Of these there are several kinds; some of a conical figure, used to illuminate churches, and in processions, funeral ceremonies, &c.

For the method of making wax-candles, see the article **WAX-CHANDLER**.

Sale or Auction by Inch of CANDLE, is when a small piece of candle being lighted, the by-standers are allowed to bid for the merchandize that is selling; but the moment the candle is out, the commodity is adjudged to the last bidder.

There is also an excommunication by inch of candle, when the sinner is allowed to come to repentance, while a lighted candle continues burning; but after it is consumed, he remains excommunicated to all intents and purposes.

CANDLE-BERRY MYRTLE, in botany. See the article **MYRTICA**.

CANDLEMAS, a feast of the church held on the second day of February, in honour of the purification of the Virgin Mary. It was borrowed from the practice of the ancient Christians, who on that day used abundance of lights both in their churches and processions, in memory, as is supposed, of our Saviour's being on that day declared by Simon, "To be a light to lighten the Gentiles."

In imitation of this custom, the Roman catholics, on this day, consecrate all the tapers and candles which they use in their churches during the whole year.

CANDY, or *Sugar-CANDY*, a preparation of sugar, made by melting and crystallizing it six or seven times over, to render it hard and transparent.

It is of three kinds, white, yellow, and red. The white comes from the loaf-sugar, the yellow from the cassonado, and the red from the muscovado. See SUGAR.

Sugar-candy is most proper in colds, because it melts slowly, and thereby gives time to the saliva to mix with it, and thus to blunt the acrimony of the phlegm.

CANDYING, in pharmacy, the act of preserving simples in substance, by boiling them in sugar.

The performance of this originally belonged to the apothecaries, but is now become a part of the business of a confectioner.

CANDY-TUFT, in botany, a low-growing annual plant, usually sown in the spring, in patches, for the ornament of the flower-garden. There are two sorts, one with purple flowers, and the other with white: both make an agreeable appearance when in blossom, and are a species of the *iberis*, which see.

Tree CANDY-TUFT. See the article *IBERIS*.

CANE, a sort of walking-stick, of which some are without knots, and very smooth and even; others are full of knots, about two inches distant from each other. These last have very little elasticity, and will not bend so well as the others.

CANE ARUNDO, in botany. See the article *REED*.

CANE, *Canna*, is also the name of a long measure, which differs according to the several countries where it is used.

At Naples, the cane is equal to 7 feet $3\frac{1}{2}$ inches English measure; the cane of Thoulouse, and the Upper Languedoc, is equal to the *varre* of Arragon, and contains 5 feet $8\frac{1}{2}$ inches; at Montpellier, Provence, Dauphine, and the Lower Languedoc, to 6 English feet $5\frac{1}{2}$ inches.

CANELLA ALBA, wild cinnamon, in the *materia medica*, the inner bark of a large bay-leaved tree, growing in the Low-lands of Jamaica, and other American islands, brought over in the form of quills; of which some are large and thick, taken from the trunk of the tree; others slenderer and thinner, from the branches, having generally pieces of a wrinkled brownish coat adhering to the outside, lined on the inside with a fine white membrane, breaking over with a close even surface, and appearing internally of an unequal, pale, brownish or yellowish white colour.

Canela alba has hitherto been rarely employed in medicine, unless as a substitute for winter's bark, which it pretty much resembles, and has been commonly mistaken for. The London college has now received it in two official compositions for alleviating the ill flavour of aloes. It is a moderately warm aromatic, of an agreeable smell, somewhat resembling that of cloves, but far weaker; and of a

pungent taste, accompanied with a considerable bitterness.

CANEPHORÆ, in Grecian antiquity, virgins who, when they became marriageable, presented certain baskets full of little curiosities to Diana, in order to get leave to depart out of her train, and change their state of life.

CANEPHORIA, in Grecian antiquity, a ceremony which made part of a feast celebrated by the Athenian virgins, on the eve of their marriage day.

CANEPHORIA is also the name of a festival of Bacchus, celebrated particularly by the Athenians, on which the young maids carried golden baskets full of fruit; which baskets were covered to conceal the mystery from the uninitiated.

CANES VENALICI, or THE TWO HOUNDS, in astronomy, a new constellation of the northern hemisphere. These two hounds are represented on the globe coupled together by the neck, and held in a string by Bootes. This constellation contains twenty-five stars, their places, &c. are as in the following catalogue.

Order.	Magn.	Name.	Bayer let.	Right Ascension.	Distance from Nor. Pole.	Var.in Right Ascen.	Var.in Declination

CANICULA, in astronomy, the same as *canis minor*. See *CANIS MINOR*.

CANICULAR DAYS, are those days, or that space

space of time, taken up by the sun in passing the constellation Canis major, or all those days in which the sun and some part of Canis major pass the meridian together, at which time Sirius, or the dog-star, and the sun rise and set nearly together; from hence they likewise are called the Dog-days.

The ancients, when they observed the heliacal rising of Sirius, usually sacrificed a brown dog, to appease its rage; for they supposed it to be the cause of the hot, sultry weather, usually felt in the dog-days: but this supposition must certainly be absurd, for in time the dog-days will happen in winter; therefore, for the same reason, they must suppose it the cause of frost and snow.

Among the Egyptians, (if we may believe several historians) there were more stars than Sirius, which they called Canicula, or the Dog-star, and by which their magi prognosticated the future events of the year. There was one which went under the name of Thot, and sometimes Anubis, situated near Cancer, which they suppose caused the swelling and sinking of the river Nile. They usually denoted the observation of the dog-star by the figure of a serpent. The figure of Anubis or Thot they usually accompanied with a full purse, the sight whereof filled the people with joy.

CANICULAR YEAR, among the Egyptians, denotes their natural year, which was computed by one heliacal rising of the dog-star to the next. This is called *Annus canarius* and *Annus cynicus*; by the Egyptians themselves the *Sotic* year, from *Soth*, a denomination given by them to Sirius. Some also call it the *Heliacal* year. The canicular year consisted ordinarily of three hundred and sixty-five days; and every fourth year of three hundred and sixty-six days, by which it was accommodated to the civil year.

The reason of their choice of the dog-star, or Sirius, to compute their time by, was not only the superior brightness of that star, but because its heliacal rising was in Egypt at a time of singular note, as falling on the greatest augmentation of the Nile, the reputed father of Egypt.

CANINE, whatever partakes of, or has any relation with, the nature of a dog. Thus,

CANINE TEETH, in anatomy, are two sharp-edged teeth in each jaw; one on each side, placed between the incisives and molares.

CANINE MUSCLES, a pair of muscles common to both lips. They arise from the hollow on each side under the os jugalis, in the os maxillare, and are inserted into the angle of the lips.

CANINE APPETITE. See BULIMY.

CANIS, dog, in zoology, the name of a comprehensive genus of quadrupeds, of the order of the fereæ.

They are distinguished from the other genera of this order, by the number of their teats, or paps, which in the dog kind are ten, four on the breast,

and six on the belly: add to this, that their feet are adapted to running; they have five toes on the fore ones, and four on the hinder.

CANIS MAJOR, or the *Great Dog*, in astronomy, a constellation of the southern hemisphere, which, according to Ptolemy, contains twenty-eight stars, Tycho thirteen, and the British catalogue thirty one.

The poets tell us, this was the dog that Jupiter set to keep Europa after he had stolen her away, and conveyed her into Crete; and for his good services placed him in heaven. Others say, it was one of the dogs of Orion; and Novidius will have it to be Tobias's dog.

The right ascension, &c. of the stars in this constellation to the year 1770, is as follows.

Order.	Magn.	Name.	Right Ascension	Distance from Nor. Pole.	Var. in Right Ascen.	Var. in Declination.

CANISTER, a large tin-box, in which tea is brought from China. They are of several sizes, holding from one pound to ten of that vegetable.

CANKER, a speck made of a sharp humour, which gnaws the flesh almost like a caustic; very common in the mouths of children.

CANKER in Trees, a term used by our farmers to express a wound or blemish in the trunk of a tree, which does not heal up by nature, but will increase and damage, if not endanged, the whole tree. These wounds are sometimes occasioned by accidents, as blows, or by the branches of one tree galling another by the motion they are put into by the winds; if this latter be the case, the offending branch must be cut off, or drawn another way, or else all remedies are vain.

The wound must be cut and enlarged every way to the quick, and all the decayed wood must be taken clean out; then the whole internal surface of the wound must be rubbed over with tar mingled with oil; and after this it must be filled up with clay and horse-dung mixed together, or with horse-dung alone, which many esteem best of all; in this case the dung must be bound over with a rag: hogs-dung is by many preferred to horse-dung for this purpose; and it is proper to add to this application the keeping of the roots cool and moist, by laying fern and nettles about them. If the canker be only in one of the boughs of the tree, the shortest way is to cut off the bough at once; if that be a large one, it should be cut off at some distance from the body of the tree; but if a small one, it should be cut off close. The adding a coat of dung, and

pond or river mud, about the roots of trees, if they are subject to this from their standing in a dry barren land, as is often the case, is a very good cure.

CANNA, in botany, a genus of plants; the flower of which is monopetalous, and divided into six parts. The lacinize are lanceolated, cohering at the bases, of which the three exterior ones are erect; the three interior ones are longer than these, and two of them are erect, and one reflex. The fruit is a roundish, scabrous, coronated, trifurcated capsule, with three cells and three valves, containing some globose seeds.

CANNABIS, hemp, in botany. See **HEMP**.

CANNACORUS, in botany, the name used by Tournefort for the canna of Linnæus. See the article **CANNA**.

CANNEL-COAL, in natural history, a substance which has a long time, though with very little reason, been confounded, both by authors and druggists, with jet. It is dug up in many parts of England in great abundance, particularly in Lancashire, where it is burnt as common fuel. It is worked into toys and utensils of various kinds, under the name of jet.

CANNEQUINS, white cotton-linens brought from the East-Indies, a very proper commodity for trading on the coast of Guinea.

CANNON, in military affairs, the machines used with gunpowder, were at first called cannon, or bombards: but this custom has long since been changed. That which is now called a cannon is a fire-arm of brass or iron, long and round, concave within, and thicker at the end opposite to its opening than at the opening, which is called its mouth. See the article **ARTILLERY**.

Its principal parts are,

PLATE XXVII, Fig. 1.

The breech A, and its button, or cascabel. The breech is the solid metal from the bottom of the concave part to the cascabel, which is the extremity of the cannon opposite to its mouth.

The trunnions I. stand out on each side like an arm, and serve to support the cannon: on these it may be poised, and held almost in equilibrio; I say almost, because the breech-end ought to be about the thirtieth part of the weight of the piece heavier than the other: as the metal is thicker at the breech than towards the mouth, the trunnions are placed nearer to the end than the other.

Fig. 2. Represents a twenty-four pounder divided longitudinally with the bore or chase, which is all the interior or concave part of the cannon; and the little chamber of the breech that receives the powder by which the cannon is fired. In a twenty-four pounder this chamber is one inch and a half in diameter, and two inches and a half in depth; and in a sixteen pounder it is one inch in diameter, and

one inch ten lines in depth. The pipe of the touch-hole comes into this little chamber at about nine lines from its inmost recess in twenty-four pounders, and at about eight in sixteen pounders.

The pipe of the touch-hole is an aperture made near the breech, through the whole thickness of the metal, by which the powder is fired that lies within the cannon. This hole is made in a small cavity resembling the inside of a scollop-shell, sunk for that purpose in the upper-part of the piece.

The ears, or handles P, called by us manillions, or dolphins, are two rings, of the same metal with the piece, placed as the trunnions, only something near the breech, made in the shape of dolphins, serpents, &c. Through these is put a rope to raise or move, mount or dismount, the cannon, which, suspended on the handles, ought to be in equilibrio; that is, the breech ought not to be heavier than the mouth.

Names of the other parts of the cannon.

- b. The platband and moulding of the breech.
- c. The region of the touch-hole.
- d. The atragal of the touch-hole.
- e. The first renfort.
- f. The platband and moulding of the first renfort.
- g. The second renfort.
- h. The platband and moulding of the second renfort.
- i. The cincture or ornament of the chain.
- m. The atragal of the cincture.
- n. The chain.
- o. The neck atragal.
- p. The neck with the border in tulip-work, [peculiar to the French.]
- q. The crown with its mouldings.
- r. The mouth.

These cannon discharge, by means of gunpowder, globes or balls of iron, called bullets.

The metal of which cannon are made, is a compound of copper, brass, and tin. The respective quantities of each of these, which should enter into this composition, is a point not decided; every founder has his own propositions, which are peculiar to himself: but the common proportion of these ingredients to a quantity of metal, is one-third of copper, one-fourth of brass, and one-seventh of tin; for example, to two hundred and four pounds of metal fit for casting, they put sixty-eight pounds of copper, fifty-two pounds of brass, and twelve pounds of tin.

With respect to iron cannon, their structure is the same with the other; they are not however capable of the same resistance as those of brass, but they cost much less. These are commonly used on ship-board, and on some occasions on shore.

Cannon are of different sizes, in proportion to which they discharge bullets of more or less weight.

Cannon were formerly made to carry a thirty-three pound, a forty-eight pound, and even a ninety-six pound bullet; and M. Saint Remy observes, in his Memoirs, that there is still one of this last sort in the city of Straßburg; but the largest battering-pieces now commonly cast are those which carry a bullet of twenty-four pounds weight, and which are therefore called twenty-four pounders; and the largest made on board his majesty's ships are forty-two pounders; but these are generally brass, and confined to ships of the first rate in our navy.

Cannon generally take their names from the weight of the bullets which they discharge; thus a piece that discharges a bullet of twenty-four pounds, is called a four-and-twenty pounder; one that carries a bullet of sixteen pounds, is called a sixteen pounder; and so of the others.

Cannon are also distinguished by the diameter of the mouth, or bore, which is generally called the caliber of the piece; so if this diameter is three, four inches, &c. the cannon is said to be a piece of three, four, &c. inches caliber.

The diameter of the bullet, or ball, ought to be about two lines, or two-twelfths of an inch, at least less than the bore of the piece, that it may be discharged with the greater ease, and not damage the piece by rubbing it too forcibly in its passage; this is called the vent of the bullet.

When the diameter of a bullet and its weight are known, it is easy to find the weight of all bullets, having the diameter given, and the diameter of all bullets, if the weight be given. Geometry has furnished certain rules for effecting this, which are mentioned among the uses of the sector.

The twenty-four pounders are used in sieges to batter and destroy fortifications; their length is eleven feet, including the length of the calcabel; and their weight ought to be five thousand four hundred pounds, or upwards; their bore is about five inches, eight line, and consequently the bullets they carry are about five inches, six lines diameter.

Besides these pieces of twenty-four pounders, there are others, viz. sixteen, twelve, eight, and four pounders.

The sixteen pounders are called demi-cannon, or culverins; their bore is four inches, eleven lines; they carry balls of four inches, nine lines diameter; their length is about ten feet, six inches, and their weight four thousand, two hundred pounds at most: there are some longer, and, among others, the piece, called the culverin of Nancy, from its having been cast in that city.

It is now common to call any piece a culverin, which is longer than other pieces of the same bore.

The twelve pounder carries bullets of four inches, three lines diameter; its length is about ten feet, and its weight three thousand two hundred pounds at most.

The eight pounder is called a bastard or demi-cannon; its length is about eight feet, ten inches; its weight ought to be two thousand, one hundred pounds at most; it carries a ball of about three inches, ten lines diameter.

The four pounder, *moyenne*, or middle size, ought to be seven feet, three inches in length; its bore is about three inches, two lines, and by consequence, the bullet it carries is no more than three inches diameter; the weight of this piece ought to be one thousand, one hundred and fifty pounds.

Besides these pieces, there are others still less, that carry from two pounds to a quarter of a pound ball; these are called *falconets*: their length is about seven feet, and their weight varies from eight hundred down to one hundred and fifty pounds.

The metal of cannon is not equally thick in all parts, but is in some measure proportioned to the force of the powder which it is to resist; at the breech, where the effort is strongest, the thickness of the metal is equal to the diameter of the bullet of the piece; at the first renfort, where the force begins to diminish, the thickness is somewhat less than at the breech; at the second, where the force is further diminished, the thickness is less than at the first; and, by the same rule, the chase has less thickness than the second renfort. The thickness of the chase gradually diminishes from the trunnions to the mouth of the piece. If a cannon was without cascabel, or button, trunnions, and mouldings, it would exactly resemble the frustum of a cone, or a cone, the small end being cut off.

If the diameter of the ball be divided into twelve equal parts, the thickness of the metal at the breech of the piece will be equal to the whole twelve; to eleven at the end of the first renfort, nine and a half at the end of the second, seven and a half at the neck astragal, the same at the extremity of the chase; and at the greatest protuberance of the border, or moulding at the muzzle, eight and a half.

With respect to the length of the piece, if it is divided into seven equal parts, from the extremity of the platband of the breech, to the extremity of the mouth, the first renfort will be two of these parts; the second renfort will terminate at the end of the third part, which is also the place of the trunnions; and the four remaining parts will be the length of the chase.

The length and thickness of each trunnion are equal to the diameter of the piece, and the length of the cascabel is two diameters of the bullet.

All these proportions have been established by experience, which has shewn, that cannon, in which they were nearly observed, have been capable of doing good service; I say nearly, because they are not kept with a geometrical exactness. *Le Blond's Elements of War*. See the articles CARRIAGE, CHAMBER, and CHARGE.

CANNULA, in surgery, a tube made of different metals, principally of silver and lead, but sometimes of iron.

They are introduced into hollow ulcers, in order to facilitate a discharge of pus or any other substance; or into wounds, either accidental or artificial, of the large cavities, as the thorax or abdomen: they are used in the operation of bronchotomy, and by some, after cutting for the stone, as a drain for the urine.

Other cannulas are used for introducing cauteries, either actual or potential, in hollow parts, in order to guard the parts adjacent to that to be cauterized from injury. They are of various figures; some being oval, some round, and others crooked.

CANOE, in the marine, a sort of Indian boat or vessel formed of the trunk of a tree hollowed, and sometimes of several pieces of the bark fastened together.

Canoes are of various sizes, according to the countries where they are formed, or the use for which they may be designed: the largest are made of cotton-tree, some of which will carry between twenty or thirty hogheads of sugar or molasses: some are made to carry sail, and for this purpose are steeped in water till they become pliant, and then their sides are extended with strong beams, on which a deck is afterwards laid. The other sorts very rarely carry sail, unless when going afore the wind; their sails, for this purpose, are sometimes made of a kind of rushes or silk-grass. They are commonly rowed with paddles, which are pieces of light wood, somewhat resembling a corn-shovel; and instead of wielding the paddle horizontally, like an oar, they row perpendicularly. The small canoes are very narrow, having only room for one person in breadth, and eight or nine lengthways. The rowers, who are generally negroes or American savages, are very expert in moving their paddles uniformly, and in ballancing them properly with their bodies, which would be difficult for a stranger to do, how well accustomed soever to the management of European boats, because the canoes are extremely light, and liable to be overturned.

The American Indians, when they are necessitated to land, to avoid a water-fall, or to cross the land from one river to another, carry their canoes on their heads, till they arrive at a place where they can launch them again.

There is a Greenland canoe in the repository of the Royal Society covered with seal-skins, and resembling a great bladder, so that however the waves dash over it, the person who manages it sits safe.

CANON, in ecclesiastical affairs, a person who possesses a revenue allotted for the performance of divine service in a cathedral or collegiate church.

CANON of Scripture, a catalogue or list of the inspired writings, or such books of the Bible as are called canonical, because they are in the number of those

those books which are looked on as sacred, in opposition to those which either are not acknowledged as divine books, or are rejected as heretical and spurious, and are called apocryphal.

The canon of Scripture may be considered either as Jewish or Christian, with respect to the sacred writings acknowledged as such by the Jews, and those admitted by the Christians.

The first canon, or catalogue of the sacred books, was made by the Jews; but who was the author of it is not so certain. The five books of Moses were, unquestioned, collected into one body within a short time after his death; since Deuteronomy, which is an abridgment of the other four, was laid in the tabernacle near the ark, according to the command he gave to the Levites: so that the first canon of the sacred writings consisted only of the five books of Moses. There were no more added to them till the division of the ten tribes; since the Samaritans acknowledge none else. However, since Moses, there were several prophets and other writers divinely inspired, who composed either the history of their times, or prophetic books, and divine writings, or psalms to the praise of God; but it cannot be discovered that, any time before the captivity, they were collected into one body, and comprized under one and the same canon. It is evident that, in our Saviour's time, the canon of the Holy Scripture was already drawn up, since he cites the law of Moses, the prophets, and the psalms, which are the three sorts of books of which that canon is composed, and which he often styles the Scripture, or the Holy Scripture.

It is generally received that Ezra was the principal author of this canon, though Nehemiah had some share in it; and that he re-established, corrected, and ordered the sacred books to be written in new characters.

The Jewish canon is generally called the canon of Ezra; but it is certain, that all the books were not received into the canon of the Scriptures in his time; for Malachi, it is supposed, lived after him; and, in Nehemiah, mention is made of Jaddua the high-priest, and of Darius Codomanus, a king of Persia, who lived at least a hundred years after his time. Dr. Prideaux, with great appearance of reason, says, it is most probable, that the two books of Chronicles, Ezra, Nehemiah, and Esther, as well as Malachi, were afterwards added in the time of Simeon the Just; and that it was not till then that the Jewish canon of the Holy Scripture was fully completed. And, indeed, these last books seem very much to want the accuracy and skill of Ezra, in their publication; for they fall short of the exactness found in the other parts of the Hebrew Scriptures. There are some authors who pretend, that the Jews have made one or more canons; and that they have added to the former the books of Tobit, Judith, Ecclesiasticus, Wisdom, and the Maccabees: but

it is most evidently true, that the Jews had no other canon but that of Ezra, nor confessed any other books for sacred, but those it contains. The two assemblies of the synagogue, which, as it is pretended, were held for that purpose, are mere chimeras; nor have any ancient writers said any thing of them.

As for the Christian church, there is no doubt but it acknowledged those books to be canonical which were cited, as of divine authority, by Christ and his apostles; the ancient catalogues of the canonical books of the Old Testament, which are to be met with in Christian writings, are conformable to the canon of the Jews, and contain no other books; the Christian church, for several of the first ages, receiving the inspired writings no farther than the Jewish canon. The first, and most ancient catalogue of this kind, is that of Melito, bishop of Sardis, who flourished in the reign of Marcus Antoninus. It agrees with the Jewish canon, excepting his omission of Esther, and that he makes Ruth and Judges two books. Origen has given us a list of the sacred books, in which he takes in Esther, and joins Ruth with Judges. St. Gregory Nazianzen divides the books of Scripture into historical, poetical, and prophetic: he reckons twelve historical books, viz. the five books of Moses, with Joshua, Judges, Ruth, the two books of Kings, Chronicles, and Eldras. Five poetical books, Job, Daniel, and the three books of Solomon. Five prophetic books, viz. four great prophets, and twelve small ones. The council of Laodicea was the first synod in which the number of the canonical books was ascertained; this council assigns only twenty-two books to the Old Testament, including Esther, and joining Baruch and the Lamentations with Jeremiah. St. Epiphanius reckons twenty-seven canonical books of the Old Testament; yet he admits no more than are in the catalogue of Origen, and observes that the Jews had reduced them to twenty-two. The third council of Carthage, in the year 397, admitted the books of Wisdom, Ecclesiasticus, Tobit, Judith, and the two books of Maccabees, into the canon. The church of Rome has agreed herein with that of Africa; for Innocent I. in his letter to Exuperius, places the same books in the canon of Scripture, as pope Gelasius, in the council held in the year 494; and the decree of pope Eugenius, and the canon of the council of Trent, agree with the canon of the council of Carthage. That the council of Trent had no prior authority to proceed on, excepting some slender pretence from the council of Carthage above-mentioned, appears from the current testimony of the Latin church.

As to the canon of the New Testament, it is to be observed, that the four Evangelists, the Acts of the Apostles, all the Epistles of St. Paul, except that to the Hebrews, and the first Epistles of St. Peter and St. John, have been received as canonical by

by the unanimous consent of all the churches in all times; the Epistle of St. James, that of St. Jude, the second Epistle of St. Peter, and the second and third Epistles of St. John, were not received by all the churches from the beginning, as canonical; but have since been acknowledged as genuine, and therefore admitted into the canon.

We must observe that the canon of the New Testament was neither settled by any synod, or single authority; this collection was formed upon the unanimous consent of all the churches, who, by constant tradition, reaching to the apostolical age, had received such a number of them as were written by inspired authors.

CANON, in monastic orders, a book wherein the religious of every convent have a fair transcript of the rules of their order frequently read among them, as their local statutes.

CANON is also used for the catalogue of saints acknowledged and canonized in the Romish church.

CANON, in music, a short composition of two or more parts, in which one leads, and the other follows: or it is a line of any length, shewing, by its divisions, how musical intervals are distinguished according to the ratios, or proportions, that the sounds terminating the intervals bear one to another, when considered according to their degree of being acute or grave.

CANON, in arithmetic, is a rule to solve all things of the same nature with the present enquiry: thus every last step in algebra is such a canon; and if turned into words, is a rule to solve all questions of the same nature with that proposed. The tables of logarithms, artificial signs, tangents, &c. are called likewise by the same name of canon.

CANON-LAW, a collection of ecclesiastical laws, serving as the rule and measure of church government.

The power of making laws was exercised by the church before the Roman empire became Christian. The canon-law that obtained throughout the West, till the twelfth century, was the collection of canons made by Dionysius Exiguus, in 520, the capitularies of Charlemagne, and the decrees of the popes, from Siricius to Anastasius.

The canon-law, even when papal authority was at its height in England, was of no force when it was found to contradict the prerogative of the king, the laws, statutes, and customs of the realm, or the doctrine of the established church. The ecclesiastical jurisdiction of the see of Rome in England was founded on the canon-law; and this created quarrels between kings and several archbishops and prelates, who adhered to the papal usurpation.

Besides the foreign canons, there were several laws and constitutions made here for the government of the church; but all these received their force from the royal assent; and if at any time the ecclesiastical courts did, by their sentence, endeavour to

enforce obedience to such canons, the courts at common law, upon complaints made, would grant prohibitions. The authority vested in the church of England of making canons, was ascertained by a statute of Henry VIII. commonly called the act of the clergy's submission; by which they acknowledged that the convocation had been always assembled by the king's writ; so that though the power of making canons resided in the clergy, met in convocation, their force was derived from the authority of the king's assenting to, and confirming them.

The old canons continued in force till the reign of James I. when the clergy being assembled in convocation, the king gave them leave to treat and consult upon canons; which they did, and presented them to the king, who gave them the royal assent: these were a collection out of the several preceding canons and injunctions. Some of these canons are now obsolete. In the reign of Charles I. several canons were passed by the clergy in convocation.

CANONESS, in the Romish church, a woman who enjoys a prebend, affixed, by the foundation, to maids, without their being obliged to renounce the world, or make any vows.

CANONESSES of *St. Augustine*, or *Royal Canonesses*, a kind of religious, who follow the order of *St. Augustine*, of which there are various congregations.

CANONICAL, something belonging to, or partaking of, the nature of a canon: thus we read of canonical obedience, which is that paid by the inferior clergy to their superiors, agreeably to the canon-law. See the article CANON-LAW.

We also meet with canonical life, canonical hours, &c. used much in the same sense.

CANONICUM, in the Greek church, the name given to certain fees paid by the clergy to their prelates, for degrees of promotion.

CANONIST, a person skilled in, or who makes profession of the canon-law. See the article CANON-LAW.

CANONIZATION, a ceremony in the Romish church, by which persons deceased are ranked in the catalogue of the saints.

CANONRY, the benefice filled by a canon. It differs from a prebend, in that the prebend may subsist without the canonicate; whereas the canonicate is inseparable from the prebend: again, the rights of suffrages, and other privileges, are annexed to the canonicate, and not to the prebend.

CANOPY, a magnificent covering, raised above an altar, throne, chair of state, pulpit, and the like.

The word canopy comes from the Greek *καλυπτριον*, a net spread over beds to keep off the gnats, from *καλυπτω*, a gnate.

CANQUES, a sort of cotton cloth made in China, which they wear next their skin, and is properly their shirt.

CANTALIVERS, in architecture, the same nearly as modillions, only the one is plain and the other carved. They are both a kind of cartouzes set at equal distances under the corona of the cornice of a building. Cantalivers which project much are at present out of fashion, and with good reason, especially in London-Streets, as they darken, by their hanging over, the upper chambers at least; and are apt to spread and communicate fire in case of a misfortune of that sort: and besides, use, convenience, and simplicity are more laudibly studied than mere ornament.

CANTAR, or **CANTARO**, in commerce, a weight used in Italy, particularly at Leghorn, to weigh some sorts of merchandizes.

There are three sorts of cantari, or quintals, one weighs one hundred and fifty pounds, the other one hundred and fifty-one, and the third an hundred and sixty: the first serves to weigh alum and cheefe, the second is for sugar, and the third for wool and cod-fish.

CANTATA, in music, a song or composition, intermixed with recitatives, airs, and different movements, chiefly intended for a single voice, with a thorough bass, though sometimes for other instruments.

CANTERBURY BELL-FLOWER, in botany, the English name for a species of the campanula. It is a biennial plant, with oblong rough hairy leaves, which are serrated on their edges. From the center arises a stiff, hairy, furrowed stalk, sending out several lateral branches from the bottom upwards, which are garnished with long, narrow, hairy, serrated leaves, placed alternately. From the places where the leaves put forth issues out the flowers on foot-stalks, diminishing gradually upwards in a pyramidal form. These are large, and blossom in June. This plant is propagated by seeds sown in the spring.

CANTHARIDES, in the materia medica, a beautiful kind of fly or winged insect, of a bright, shining, greenish, golden colour, with some admixture of bluish. They were formerly brought from Spain, and hence are still commonly called Spanish flies. They are not, however, peculiar to that kingdom, France, some parts of Germany, and other countries, produce abundance. It is principally in the spring, and on the poplar and ash-trees, that they are met with.

The usual way of killing them is by the steam of strong or distilled vinegar. The flies are put into a clean pot, which is covered with a hair cloth, and then inverted upon another pot containing the vinegar warmed by a little fire made underneath, the juncture of the two pots being closely luted to confine the steam. The flies are afterwards thoroughly dried, and packed up secure from the air. In long keeping, they fall by degrees into a greyish or brownish light powder, and in this state are unfit for use, their intrinsic qualities perishing with their ex-

ternal form. The wings are the most permanent part, these remaining entire after the body of the fly has mouldered into dust.

Cantharides, when fresh, have a strong fetid smell: tasted, they make at first no impression upon the tongue, but in a little while they discover a degree of acrimony, and a kind of pitchy flavour. Applied to the skin, they raise a blister on the part. The usual blistering-plasters are composed of powdered cantharides and some common plaster, in the proportion of one part of cantharides, or two, six, eight, or more of the plaster, according as the composition is required to be more or less active.

Taken internally, in the dose even of a few grains, they generally occasion violent irritation and inflammations. They act in a peculiar manner upon the kidneys, and the urinary and feminal vessels: when applied only externally as a blister to remote parts, they often affect the bladder, and bring on a difficulty and pain in making water. They are nevertheless given inwardly in small doses, both with safety and advantage, in some refractory disorders, which baffle the force of medicines of less activity. Dr. Græneveld, who was imprisoned in England for having ventured to exhibit them, published a treatise in defence of his practice and of the utility of the medicine. He employs camphor for correcting the virulence of the cantharides; but the best remedies against the ill effects of this, as of other stimulating drugs, are milk and expressed oils.

CANTHI, in anatomy, cavities at the extremities of the eye-lids, commonly called the corners of the eye: the greater of them, or the greater canthus, is next the nose; the lesser, or the little canthus, lies towards the temple.

CANTHUS, in chemistry, the lip of a vessel, or that part of it which is a little hollowed or depressed, for the easy pouring off of liquors.

CANTICLES, a canonical book of the Old Testament. The Talmudists ascribe it to Hezekiah, but the learned are agreed that king Solomon was the author of it; and his name is prefixed to it in the title of the Hebrew text, and of the ancient Greek version.

It is a kind of epithalamium, in the form of an idyllium or bucolic, in which are introduced, as speakers, a bridegroom, a bride, the friends of the bridegroom, and the companions of the bride. The bridegroom and bride express their love for each other in very tender and affectionate terms; for which reason the Jews never allowed this book to be read by any, till they were at least thirty years of age.

Some authors are of opinion, that Solomon's design in this piece, was to describe his amour with the Shunamite, or with the daughter of Pharaoh: on the contrary, others take it to be wholly allegorical, and understand it of the spiritual love of God to-
wards

wards his church. Some have pretended to discover in it five scenes; but others, with more justice, distinguish it into seven days, during which the ancients celebrated their nuptials.

CANTIMAROUS, or **CATIMAROUS**, a kind of raft made of three or four hollowed trunks of trees, tied together with ropes of cocoa, with a triangular sail in the middle made of mats. They are used by the inhabitants of the coast of Coromandel, to go a fishing, and to trade along the coast.

CANTO, in music, the treble, or at least the higher part of the piece.

This word more properly signifies the first treble, unless the word *secundo*, for the second, or *ripieno*, for the treble of the grand chorus, be added.

CANTO-CONCERTANTE, is the treble of any principal part in a concerto, and generally plays or sings throughout.

CANTONED, in architecture, is when the corner of a building is adorned with a pilaster, an angular column, rustic quoins, or any thing that projects beyond the naked part of a wall.

CANTONED, or **CANTONIZED**, *Cantonée*, in heraldry, the position of such things as are borne with a cross, &c. between. He bears gules, a cross argent cantoned with four scallop-shells.

CANTONING, in military affairs, the allotting distinct and separate quarters to each regiment of an army; the town, where they are quartered, being divided into so many cantons, or divisions, as there are regiments.

CANTRED, or **CANTREF**, signifies an hundred villages, being a British word, compounded of the adjective *cant*, that is, hundred, and *tres*, a town or village. In Wales some of the counties are divided into cantreds, as in England into hundreds.

CANT-TIMBERS, in naval architecture, the most crooked timbers in a ship; they are situated at the two ends, and are called so, from their being canted, or raised obliquely from the keel, in contradistinction to those whose planes are perpendicular to it: the upper part of those in the bow or fore-end of the ship, are inclined to the prow, as those in the after, or hind-part, incline above to the stern-post.

The principal of those last is the fashion-piece, which terminates the stern.

CANVAS, in commerce, a very clear unbleached kind of hemp, or flax, wove very regularly in little squares. It is used for working tapestry with the needle, by passing the threads of gold, silver, silk, or wool, through the intervals or squares.

CANVAS is also a coarse cloth of hemp, unbleached, somewhat clear, which serves to cover women's stays, also to stiffen men's cloaths, and to make some other of their wearing apparel, &c.

CANVAS is also a very coarse cloth made of

hemp, unbleached, serving to make towels, and answering other domestic purposes. It is also used to make sails for shipping, &c.

CANZONE, in music, signifies, in general, a song where some little figures are introduced: but it is sometimes used for a sort of Italian poem, usually pretty long, to which music may be composed in the style of a cantata. If this term be added to a piece of instrumental music, it signifies much the same as cantata: if placed in any part of a sonata, it implies the same meaning as allegro, and only denotes that part, to which it is prefixed, is to be played or sung in a brisk and lively manner.

CANZONETTA, a diminutive of canzone, denoting a little short song: the canzonette Neapolitane have two strains, each whereof is sung twice over, as the vaudevilles of the French: the canzonette Siciliane are a species of jig, the measure whereof is usually twelve-eights, and six-eights, and sometimes both are rondeaus.

CAP, a part of dress made to cover the head, and much in the figure thereof.

CAP of Maintenance, one of the regalia, or ornaments of state belonging to the kings of England, before whom it was carried at the coronation, and other great solemnities. Caps of maintenance are also carried before the mayors of the several cities in England.

CAP of a Gun, a piece of lead which is put over the touch-hole of a gun, to keep the priming from being wasted or spoiled.

CAP, in the marine, a strong thick piece of wood firmly hooped with iron, having two holes perpendicularly cut thro' it, one of which is square, and the other round. The former is firmly fixed on the upper end of the lower-mast, and the latter keeps the top-mast steady, which slides up through it, till the heel, or lower end, reaches the top, where it is fastened. See the article **FID**.

In the same manner as the top-mast slides up through the cap of the lower-mast, does the top-gallant-mast slide up through the cap of the top-mast. See **CAP**, Plate XXVIII, fig. 1. See also **MAST** and **CROSS-TREES**.

CAPACITY, in a general sense, an aptitude or disposition to retain or hold any thing.

CAPACITY, in geometry, is the solid content of any body; also our hollow measures for ale, beer, wine, corn, &c. are called measures of capacity.

CAPACITY, in law, the ability of a man, or body politic, to give or take lands, or other things, or fee actions.

CAPARASON, or **HORSE-CLOTH**, a sort of cover for a horse.

CAPAX, in the order of Malta, a name given to the knights that have resided five years at Malta, have made four caravans, or sea-campaigns, and are in a condition of coming to a command.

CAPE, in law, a judicial writ concerning plea of lands or tenements, and is divided into *cape magnum* and *cape parvum*, both of which affect things immoveable; and besides these, there is a *cape ad valenciam*.

CAPE, in geography, a promontory, or headland, which projects into the sea farther than the rest of the coast.

CAPE Magnum, or the grand cape, lies before appearance, to summon a tenant to answer the default, and also aver to the defendant.

The CAPE Parvum, is after appearance and view granted, and it summoneth the tenant to answer the default only.

CAPE ad Valenciam, is a species of *cape magnum*, where one being impleaded, and on a summons to warrant lands, a vouchee does not come at the day; whereupon, if the defendant recovers of the tenant, he shall have this writ against the vouchee, and recover so much in value of his lands, in case he hath so much; and if not, there shall be an execution of such lands and tenements as shall after descend to him in fee; or if he purchases afterwards, there may be a re-summmons, &c. against him.

CAPELET, a disease in horses, when the tip of the hock is moveable, and more swelled than ordinary.

CAPELLA, in astronomy, a bright star in the left shoulder of the constellation Auriga. For its place, &c. see the constellation AURIGA.

CAPER-BUSH, *Capparis*, in botany. See the article **CAPPARIS**.

Bean-CAPER. See **ZYGOPHYLLUM**.

The buds of this plant make a considerable article in commerce; they are imported from Italy and France in pickle, and used in sauces, &c.

The caper-bark of the shops is not the bark of the branches, but that of the roots of the shrub which produces it.

It is an aperient and attenuant, and is recommended in nephritic cases, and in dropsies, jaundices, and many other chronic diseases: but the present practice does not pay any regard to it.

CAPHAR, a duty which the Turks raise on the Christians, who carry or send merchandizes from Aleppo to Jerusalem, and other places in Syria.

CAPI-AGA, or **CAPOU AGASSI**, a Turkish officer, who is, as it were, grand-master of the *terzaglio*.

CAPIAS, in law, a writ of two sorts, one before judgment in an action, and the other after: that before judgment is called *capias ad respondendum*, where an original is sued out, &c. to take the defendant, and make him answer the plaintiff; and that after judgment is the *capias ad satisfaciendum*, &c.

CAPIAS AD SATISFACIENDUM is a writ of execution that issues on a judgment obtained, and lies where any person recovers in a personal action, as

for debt, damages, &c. in which cases this writ issues to the sheriff, commanding him to take the body of him against whom the debt is recovered, who is to be kept in prison till he make satisfaction.

CAPIAS CONDUCTOS AD PROFICISCENDUM, an original writ which lies, by the common law, against any soldier who has covenanted to serve the king in war, and appears not at the time and place appointed. It is directed to two of the king's sergeants at arms, to arrest and take him wherever he can be found, and to bring him *coram consilio nostro*, with a clause of assistance.

CAPIAS PRO FINE, is a writ lying where a person is fined to the king, for some offence committed against a statute, and he does not discharge the fine according to the judgment; therefore his body shall be taken by this writ, and committed to gaol till the fine is paid.

CAPIAS UTLEGATUM, a writ which lies against any one outlawed, upon any action personal or criminal, by which the sheriff is ordered to apprehend the party outlawed, for not appearing on the exigent, and keep him in safe custody till the day of return, when he is to present him to the court, to be there farther ordered for his contempt.

CAPIAS IN WITHERNAM, a writ that lies for cattle in *Withernam*; that is, where a distress taken is driven out of the country; so that the sheriff cannot make deliverance upon a replevin; then this writ issues, commanding the sheriff to take as many beasts of the distrainer.

CAPIGI, in the Turkish affairs, the name of certain inferior officers belonging to the *seraglio*, to the number of five hundred, whose business it is to assist the janizaries in guarding the first and second gate of that palace; whence also the name *capigi*, which signifies a gate.

CAPILLAMENT, in a general sense, signifies a hair, whence the word is applied to several things, which, on account of their length or their fineness, resemble hairs: as,

CAPILLAMENTS of the Nerves, in anatomy, the fine fibres, or filaments, whereof the nerves are composed.

CAPILLARY, in a general sense, an appellation given to things, on account of their extreme fineness, or resembling hair.

CAPILLARY FILAMENTS, in botany, are the fine slender parts of the stamina, (conspicuous in many flowers) like hairs, which supports the anthers or apices.

CAPILLARY FRACTURE, a small and almost insensible fracture of the skull. See **FRACTURE**.

CAPILLARY ORES, in mineralogy, the same with those otherwise denominated arborescent, or striated.

CAPILLARY PLANTS, are such plants as have

no main stem, but their leaves arise from the root, upon pedicles, and produce their seeds on the back of their leaves, as the fern, maiden-hair, &c.

CAPILLARY TUBES, in physics, are glass pipes, the diameter of whose bore is at most but about one-tenth of an inch; though any pipe, whose cavity does not exceed that magnitude, may be called a capillary tube. The phenomena of capillary tubes being such as contradict a known law in hydrostatics, viz. that a fluid rises in a tube to the same height with the level of its source, and likewise of affinity with the ascent of the sap through the stems of plants, for the nourishment of their fruit, and with divers other operations of nature; it has been thought of no small moment in philosophy, to find out and establish their true cause, which after numerous experiments, and several conjectures about it, is found to be no other than the attraction of cohesion, by which small particles of matter mutually adhere together, and form large bodies. See *Attraction of Cohesion*.

Mr. Hauksbee, after having made many experiments to account for the ascent and suspension of water in glass tubes, assigns the attraction of the concave surface, in which the liquor is suspended to be the cause; but Dr. Jurin, in a paper read before the Royal Society, and printed in number 355 of the Philosophical Transactions, denies the above to be the cause, which he demonstrates thus: Since, in every capillary tube, the height to which water will spontaneously rise, is reciprocally as the diameter of the tube, it follows, that the surface, containing the suspended water in every tube, is always a given quantity: but the column of the water suspended, is as the diameter of the tube. There, if the attraction of the containing surface be the cause of the water's suspension, it will follow, that equal causes produce unequal effects, which is absurd.

To this it may perhaps be objected, that in two tubes of unequal diameters, the circumstances are different, and therefore the two causes, though they be equal in themselves, may produce effects that are unequal. For the lesser tube has not only a greater curvature, but those parts of the water, which lie in the middle of the tube, are nearer to the attracting surface than in the wider. But from this, if any thing follows, it must be, that the narrower tube, it will suspend the greater quantity of water, which is contrary to experiment; for the columns suspended are as the diameters. But as experiments are generally more satisfactory in things of this nature than mathematical reasoning, it may not be amiss to make use of the following.

The tube *cd* (Plate XXVIII, fig. 2.) is composed of two parts; in the wider of which the water will rise spontaneously to the height of *bf*; but the narrower part, if it were of a sufficient length, would raise the water to a height equal to *cd*. This tube

being filled with water, and the wider end *c* immersed in the stagnant water *ab*, the whole continues suspended. But if the narrower end be immersed, (as in fig. 3.) the water immediately subsides, and stands at last at the height *dg*, equal to *bf*. For which it is manifest, that the suspension of the water, in the former part of this experiment, is not owing to the attraction of the containing surface; since, if that were true, this surface, being the same when the tube is inverted, would suspend the water at the same height, which we think sufficiently shews that Mr. Hauksbee's hypothesis is false.

The real cause of this phenomenon, is the attraction of the periphery, or rather of the small annular portion of the inside of the tube, to which the upper surface of the water is contiguous, and coheres: for this is the only part of the tube from which the water must recede upon its subsiding, and consequently the only one, which, by the force of its cohesion or attraction, opposes the descent of the water.

This likewise is a cause proportionable to the effect which it produces, since that periphery, and the column suspended, are both in the same proportion as the diameter of the tube. Though from either of those particulars it were easy to draw a just demonstration, yet, to put the matter out of all doubt, it may be proper to confirm this assertion, as we have done the former, by actual experiment.

Let therefore *edc* (Plate XXVIII, fig. 4.) be a tube, like that made use of in the former experiment, except that the narrower part is of a greater length, and let *af* and *bg* be the heights to which the water would spontaneously rise in the two tubes *ed* and *dc*. If this tube have its wider orifice *c* immersed in the water *ab*, and be filled to any height less than the length of the wider part, the water will immediately subside to a level with the point *g*; but if the surface of the contained water enter never so little within the smaller tube *ed*, the whole column *dc* will be suspended, provided the length of that column do not exceed the height *af*. In this experiment it is plain, that there is nothing to sustain the water at so great a height, except the contact of the periphery of the lesser tube, to which the upper surface of the water is contiguous; for the tube *dc*, by the supposition, is not able to support the water at a greater height than *bg*.

When the same tube is inverted (as in fig. 5.) and the water is raised into the lower extremity of the wider tube *cd*, it immediately sinks, if the length of the suspended column *db* be greater than *gb*; whereas, in the tube *de*, it would be suspended to the height *af*; from which it manifestly appears, that the suspension of the column *db* does not depend on the attraction of the tube *de*, but upon the periphery of the wider tube, with which its upper surface is in contact.

Though these experiments seem to be conclusive,
yes

yet it may not be improper to prevent an objection, which naturally presents itself, and which at first view may be thought sufficient to overturn the above theory. For since the periphery of the tube *ed* (fig. 4.) is able to sustain no more than a column of the length *af*, contained in the same tube; how comes it to sustain a column of the same length in the wider tube *de*, which is as much greater than the former, as the section of the wider tube exceeds that of the narrower? Again, if a periphery of the wider tube *de* (fig. 5.) be able to sustain a column of water in the same tube of the length *bg*; why will it support no more than a column of the same length in the narrower tube *ed*? which queries may likewise be made with regard to fig. 1 and 2.

The answer is easy, for the moments of these two columns of water are precisely the same, as if the sustaining tubes *ed* and *cd* were continued down to the surface of the stagnant water *ab*; since the velocities of the water, where those columns grow wider or narrower, are to the velocities of the attracting peripheries, reciprocally, as the different sections of the columns.

CAPILLARY Vessels, in anatomy, are the smallest or extreme parts of the veins and arteries.

CAPILLITIUM Veneris, in philosophy, the fine threads often seen floating in the air during the autumn. See **AIR-THREADS**.

CAPILUS Veneris, in botany. See the article **MAIDEN-HAIR**.

CAPISTRUM, in surgery, the name of a bandage used in case of fractures of the jaw.

CAPITAL, in a general sense, implies the head, chief, or principal of a thing.

The word is formed from the Latin, *caput*, the head, source, or beginning.

CAPITAL, in geography, denotes the principal city of a kingdom, province, or state. See **METROPOLIS**.

CAPITAL, among merchants, &c. implies the sum of money which individuals advance to make up the common stock of a partnership when it is first formed. It is also used to signify the stock with which a merchant first begins trade on his own account. It likewise denotes the fund or stock of a trading company or corporation.

CAPITAL Crime, implies a crime which subjects the criminal to a capital punishment, or loss of life.

CAPITAL, in architecture, is the uppermost part of a column or pilaster, serving as the head or crowning, placed immediately over the shaft, and under the entablature.

The capital is the principal and essential part of an order of a column or pilaster, and is of a different form in different orders, becoming the distinguishing characteristic between them. Vitruvius tells us that Callimachus, an ingenious statuary of Athens, invented the first regular capital from the

following accident. An Athenian old woman happening to place a basket, covered with a square tile, over the root of an acanthus, which grew on the grave of a young Corinthian lady, the plant shooting up the following spring, encompassed the basket all round, till, meeting with the tile, it curled back in a kind of scrolls. The above sculptor passing by, and observing it, executed a capital on this plan, representing the tile by the abacus, the leaves of the acanthus by the scrolls, and the basket by the body of the capital.

The **Tuscan CAPITAL** is the most simple and unadorned of all the rest; its members, or parts, are four only, viz. an abacus *a*; (Plate XXVIII, fig. 6.) an ovolo or quarter round *b*; a collarino or neck *c*; and an astragal *d*; the latter indeed properly belongs to the flut or flaut.

The character which distinguishes this capital from the Doric, &c. is, that the abacus is square and quite plain, having no ogee or other moulding; and that there are no annulets under the ovolo. Authors indeed vary a little with regard to the character of the Tuscan capital.

Vignola, for instance, gives the abacus a fillet instead of an ovolo: Vitruvius and Scamozzi add an astragal and fillet between the ovolo and neck: Serlio only a fillet; and Philander rounds the corners of the abacus.

In the Trajan column there is no neck, the astragal of the shaft being confounded with that of the capital.

The height of this capital is the same with that of the base, viz. one module, or semidiameter. Its projecture is equal to that of the bottom of the column, viz. five-eighths of the module.

The **Doric CAPITAL** has three annulets, or little square members, underneath the ovolo, instead of the astragal in the Tuscan, besides the abacus, an ovolo and a neck, all which it has in common with the former; and a talon, cyma, or ogee, with a fillet over the abacus. See Plate XXVIII, fig. 7.

Authors are also divided with regard to the characters of this capital. Palladio, Vignola, &c. put roses under the corner of the abacus, and also on the neck of this capital.

Vitruvius makes the height of this capital equal to half the diameter of the column below; and this height being divided into three parts, the first goes to the neck, the second to the bouldin, and the third to the uppermost part of the capital.

The **Ionic CAPITAL** is composed of three parts; an abacus, consisting of an ogee; under this a rind, which produces the volutes or scrolls, the most essential parts of this capital; and at the bottom an ovolo or quarter round. The astragal under the ovolo belongs to the shaft: the middle part is called the rind or bark, from its supposed resemblance to the bark of a tree, laid on a vase, whose brim is represented

Capelary Tubes.

Fig. 1. Cap.

Fig. 2.

Fig. 3.

Fig. 4.

Fig. 5.

Fig. 6. Tuscan Capital.

Fig. 7. Doric Capital.

Fig. 9. Modern Ionic Capital.

Fig. 10. Corinthian Capital.

Fig. 11. Composite Capital.

represented by the ovolo, and seeming to have been shrunk up in drying, and to have been twisted into the volutes. The ovolo is adorned with eggs, as they are sometimes called from their oval form. See Plate XXVIII. fig. 8.

The height of this capital, according to Mr. Perrault, is eighteen minutes, and its projecture one module, seven-tenths.

The differences in the character of this capital flow chiefly from the different management of the volutes, and consist in the following particulars:

1. That in the antique and some of the moderns, the eye of the volute does not answer the astragal of the top of the shaft, as Vitruvius and some of the moderns make it. 2. That the face of the volutes, which usually makes a flat, is sometimes curved and convex, so that the circumvolutions go advancing outwards, as is frequent in the antique. 3. That the border, or rim of the scroll in the volute, is sometimes not only a plain sweep, but the sweep is accompanied with a fillet. 4. That the leaves which invest the balluster are sometimes long and narrow, sometimes larger and broader. 5. That the two faces of the volutes are sometimes joined at the outward corner, the ballusters meeting in the middle, to form a regularity between the faces on the front and back of the building, with those of the sides. 6. That among the moderns, since Scamozzi, the Ionic capital has been altered, and the four faces made alike, by taking away the balluster, and hollowing all the faces of the volutes inwards, like the Composite capital. 7. That Scamozzi and some others make the volutes to spring out of the ovolo, as from a base; whereas, in the antique, the bark passes between the ovolo and abacus quite straight, only twisting at its extremities to form the volute. And lastly, that of late the sculptors have added a kind of small festoons, which spring from the flower, whose stalk lies on the circumvolution of the volute. See fig. 9.

The *Corinthian CAPITAL* is the richest of all the orders, and imputed to Callimachus, an Athenian statuary, as we have already observed. It is adorned with eight volutes *a*, (Plate XXVIII. fig. 10.) a double row of leaves *b*, and eight scrolls *c*, situated round a body called, by some, campana or bell, and by others tambour or drum.

The height of this capital is two modules, and one-third, and its projecture one module, and one-third.

The differences in the characters of this capital are: 1. That in Vitruvius, and others, the leaves are those of the acanthus; whereas, in the antique, they are usually those of the olive-tree. 2. That the leaves are commonly unequal, the lower being made the taller; though sometimes all equal; nor are there instances wanting where the lower leaves are the shorter. 3. The leaves are sometimes ruffled, sometimes quite plain; the first row generally bellies out towards the bottom, but at other times

they are straight. 4. Sometimes the horns of the abacus are sharp at the corner, but most commonly the corners are cut off. 5. There is some difference in the form and size of the rose. 6. The volutes are sometimes joined to each other, and sometimes wholly separated. 7. Sometimes the spires of the volutes continue twisting even to the end, in the same course; and sometimes they are turned back again near to the center, in the form of the letter S.

The *Composite CAPITAL* is an invention of the Romans, and is composed of the double row of leaves in the Corinthian, and the volutes in the Ionic. See Plate XXVIII. fig. 11.

The height of this capital is two modules, and one-third, and the projecture one module, and two-thirds.

The differences of its character consist in the following particulars: 1. That the volutes, which generally descend and touch the leaves, are in some works of the antique separated from them. 2. That the leaves are sometimes unequal in height, the lower row being the taller; and sometimes both are equal. 3. That the volutes of the moderns generally spring out of the base; whereas, in the antique, they run straight the whole length of the abacus, over the ovolo, without striking into the vase. 4. That the volutes, whose thickness is contracted in the middle, and enlarged both above and below in the antique, have their sides parallel in the works of the moderns. 5. That the volutes, which have generally been made as if solid both by the ancients and moderns, are now made much lighter and more airy; the folds standing hollow, and at a distance from one another.

Attic CAPITAL, that which has leaves of partition in the gorge.

Angular CAPITAL, that which supports the return of an entablature at the corner of the projecture of a frontispiece.

CAPITAL of a Balluster, that part which crowns a balluster, resembling sometimes the capital of some order, generally the Ionic.

CAPITAL of a Triglyph, the plat-band over the triglyph, called by Vitruvius *tenia*. It is sometimes a triglyph, and performs the office of a capital to the Doric pilaster.

CAPITAL of a Nich, a kind of small canopy made over a shallow nich, to cover a statue.

CAPITAL of a Lantern, a covering, sometimes of one form, and sometimes of another, which finishes the lantern of a dome.

CAPITAL of a Bastion, implies a line drawn from the point of the bastion to the angle of the polygon; or from the point of the bastion to the middle of the gorge.

CAPITALS, among printers, large or initial letters, with which all periods, verses, &c. commence.

C A P

CAPITATED PLANTS, in botany, a name given by Mr. Ray to those plants, whose seeds, with their down, are included in a scaly calyx, or cup; of this sort are the thistle, artichoke, and divers others.

CAPITATION, a tax or imposition raised on each person, in consideration of his labour, industry, office, rank, &c.

CAPITE, in law, an ancient tenure of land, held immediately of the king, as of his crown, either by knight's service, or foccage. It is now abolished.

CAPITOL, in antiquity, a celebrated castle erected on the summit of the Mons Capitolinus at Rome, and contained a temple dedicated to Jupiter, in which the senate formerly assembled. The nave of this structure was sacred to Jupiter, one of the wings to Juno, and the other to Minerva. In this beautiful edifice, which was richly adorned with ornaments, were contained the most sacred deposits of religion, such as the ancyliæ, the books of the Sybils, &c.

CAPITOLINE Games, in antiquity, annual games, instituted by Camillus, in honour of Jupiter Capitolinus, and in commemoration of the Capitol's not being surprized by the Gauls.

There was also another kind of Capitoline games instituted by Domitian, when rewards and crowns were bestowed on the poets, orators, historians, and musicians. These were celebrated every five years.

CAPITULA RURALIA, assemblies or chapters held by rural deans and parochial clergy, within the precinct of each deanry; held at first every three weeks, afterwards once a month, and more solemnly once a quarter.

CAPITULATION, in military affairs, a treaty made between the garrison or inhabitants of a place besieged, and the besiegers, for delivering up the place on certain conditions expressed in the treaty.

CAPITULATION, in the German polity, implies a contract made by the emperor with the electors, in the name of all the princes and states of the empire, before he is declared emperor, and which he ratifies before he is raised to the Imperial dignity.

CAPITULUM, among botanists, signifies the head or top of any flowering plant, and is the same as what is more commonly called umbel, which see.

CAPIVI, or **COPAIBA**. See **BALSAM of Copaiba**.

CAPOC, a sort of cotton as soft as silk, but so fine and short, that it cannot be spun. It grows in the East-Indies, and also near the river Guaiacul in South-America, where it is used to fill beds, &c.

CAPON, a cock chicken, gelded as soon as left by the hen, or at least as soon as he begins to crow.

C A P

CAPON'S TAIL-GRASS, the same with *festuca*. See **FESTUCA**.

CAPONIERE, or **CAPONNIERE**, in fortification, a work sunk about four or five feet deep, on the glacis of a place; the earth that is thrown out of it serves to form a parapet of two or three feet high, furnished with loop-holes, or small embrasures; it is covered over head with strong planks, on which are laid clays, or hurdles, to support the earth, with which the whole is covered. It will contain about fifteen or twenty men, who fire through the loop-holes upon the besiegers. Caponieres are sometimes made in the bottom of a dry moat.

CAPPADINE, a sort of silk flock taken from the upper part of the cocoon, after the silk is wound off.

CAPPANUS, a name given by some authors to the worm which adheres to and gnaws the bottom of a ship.

The cappanus is extremely pernicious to ships, particularly in the East and West-Indies; to prevent this, several ships have lately been sheathed with copper, particularly his Majesty's ships, *Alarm*, *Tartar*, and *Japon*.

CAPPARIS, caper, in botany. See **CAPER**.

CAPPARIS, the caper-bush, in botany, a polyandrious plant, whose characters are, it hath a large woody root, from whence proceed various stalks covered with a white bark, which sends out many lateral branches, armed with hard sharp spines, and on which the leaves are alternately disposed: these are round, smooth, and entire. At the intermediate joints, between the branches, come out the flowers upon long foot-stalks: each of these consists of four large, obtuse, spreading petals, with numerous filiform filaments, topped with inclined oblong antheræ. The fruit is an unilocular fleshy berry, and contains a number of kidney-shaped seeds. In Italy it grows wild among the ruins of old buildings, &c. but in other places it is cultivated.

What goes by the name of capers, (which are common as a pickle) are the buds of the flowers before they are opened, which are first laid in the shade for about four hours, and then put in vinegar for eight days; after which they are taken out, lightly pressed, and put into fresh vinegar for eight days more: this is repeated the third time, and then they are put into calks for sale. They make a considerable article of commerce, and are used in sauces, and are good to excite a languid appetite. The bark of the root is said to be aperient and dissolvent; but it is not much in use.

CAPRA, the goat, in zoology. See **GOAT**.

CAPRA-SALTANS, in meteorology, a fiery meteor or exhalation, sometimes seen in the atmosphere. It forms an infected line, resembling in some measure the caperings of a goat, whence it has its name.

CAPRARIA, in botany, a didynamious plant which grows naturally in several parts of America; the

CAPRICORN.

the stalk of which is angular and green, about a foot and a half high, sending out branches at every joint. The leaves are placed round the branches by threes, with short foot-stalks: these are oval, hairy, and slightly indented on their edges. The flowers are produced at the wings of the leaves; each of which consists of a monopetalous campanulated corolla, cut at the top into five parts. The germen is conical, which afterwards becomes an oblong-conic capsule, compressed at the point, having two cells, containing a number of roundish seeds.

CAPREA, or CAPREOLUS, the roe-deer, in natural history, an animal of the deer-kind, with rounded, erect, and ramose horns.

CAPRICORNUS, or CAPRICORN, in astronomy, one of the twelve signs of the zodiac, represented on the globe in the form of a goat, with a fish's tail, as in Plate XXIX.

It is the tenth sign in order, and is marked thus ♐. According to Ptolemy and Tycho, it contains nineteen stars, Hevelius twenty-nine, and Flamsteed fifty-one.

This constellation is very properly represented by the wild goat, whose nature being to seek its food from the bottom to the top of mountains, climbing from rock to rock, fitly emblemized the ascent of the sun, from the lowest point, in the beginning of this sign, to its highest pitch or summit, in the summer solstice.

The poets tell us that this was Pan, the god of the shepherds, whom they feign in this manner. The gods having war with the giants, gathered themselves together in Egypt. Typhon, the giant, pursued them thither, whereby the gods were brought into a quandary, that happy was he who, by changing his shape, might shift for himself. Jupiter turned himself into a ram, Apollo became a crow, Bacchus a goat, Diana a cat, Juno a cow, Venus a fish; but Pan, leaping into the river Nilus, turned the upper-part of his body into a goat, and the lower part into a fish. Jupiter, wondering at his strange device, would have that image translated into heaven, and made one of the twelve signs. The hinder-part of this sign, being represented by a fish, is supposed to betoken, that when the sun passes the latter part of this sign, that it will be inclinable to rain. Others suppose, that this was the goat that suckled Jupiter, and that after it was dead, he made a shield of its skin, called Ægis, with which he singly combated the giants; after which he restored the goat to life again, and placed her in heaven among the constellations. This last supposition we think a little absurd, for Capricorn is represented on the globe with the head of a he-goat, therefore Jupiter could with little probability be suckled by him, except the poets supposed he-goats to give milk in those days.

CAPRIFOLIUM, in botany, a name given by former authors to the honey-suckle; but comprehended under the *Lonicera* of Linnæus. See the articles **HONEY-SUCKLE** and **LONICERA**.

CAPRIMULGUS, the goat-fucker, in ornithology. See **HIRUNDO**.

CAPRIOLES, in the manege, imply the leaps made by a horse in the same place, without advancing, in such a manner, that when he is at the height of the leap, he jerks out his hinder legs.

CAPSICUM, Guinea pepper, in botany, a genus of pentandrious plants, the flower of which is monopetalous, and rotated with a short tube, an open, plicated border, and divided into five broad and sharp-pointed segments. The filaments are small and subulated, topped with oblong antheræ, which are connected. The fruit, in some species, is a globular berry; in others heart-shaped, and in some irregular; but in all is soft and pulpy: it hath two or more cells, which contain a number of kidney-shaped compressed seeds. This genus contains several species, some of which are annual, and the others perennial. The annual sorts are most of them raised on hot-beds in the spring, either for the ornament of the flower-garden, or for pickling when green; for which purpose they are very well adapted to those palates that are fond of hot fauces. One of the species, called in the West-Indies bird-pepper, is the basis of the powder brought from thence under the name of Cayan-pepper; and it may be remarked, that this fruit, perhaps the strongest of the aromatic stimulants, is used freely by the natives of the warmer climates: possibly these pungent antiseptic kinds of substances may be more salubrious there than with us, as they seem qualified to resist or correct the putridinous colliquation of the humours which immoderate heat produces.

CAPSQUARES, in gunnery, strong plates of iron, which come over the trunnions of a gun, to keep it fast in the carriage.

They are fastened by a hinge to the prize-plate, that they may lift up and down, and form an arch of a circle in the middle to receive a third part of the thickness of the trunnions, two-thirds being let into the carriage. The other end is fastened with two iron wedges, called the forelocks and keys. At sea, the capsquares are called clamps. See the article **CLAMP**.

CAPSTERN, or **CAPSTAN**, in naval architecture, a strong, massy column of timber, let down through the decks of a ship, to raise any great purchase, by heaving round horizontally.

A capstern is composed of several parts. See Plate XXX. *fig. 1.* and *2.* where *A* is the main post, *b* the whelps, *c* the drum-head, and *d* the spindle.

The whelps rise out like buttresses from the main body of the capstern; to enlarge the sweep, that a

greater portion of the cable may be drawn into the ship, or whatever rope they may be heaving on, at every revolution of the capstern: they reach from the lower-part of the drum-head downwards to the deck, and are described in *fig. 1.* of Plate XXX. being the horizontal section of the body of a capstern.

PLATE XXX. *fig. 1.* and *2.*

The drum-head *c* is a broad cylindrical piece of wood, resembling a mill-stone, of the same stock with the rest of the body: in the outside of this are cut a number of holes parallel to the deck, to receive the bars.

The spindle, which is shod with iron, is the axis or foot, which the capstern rests on, and turns round in the saucer, which is a sort of iron socket, fixed on a wooden block or standard, called the step, resting on the beams.

Besides the different parts of the capstern mentioned, it is furnished with several appurtenances, as the bars, the pins, the pawls, and swifter.

The bars are long pieces of wood or arms thrust into a number of square holes, cut into the drum-head all round: they appear like the radii of a circle, and are for heaving the capstern round to draw the cable into the ship, or raise any great purchase; the men pressing their breasts to the bars, and walking about the capstern till the operation is finished.

The pins are little bolts of iron thrust perpendicularly through the holes of the drum-head, when the bars are fixed, to prevent the bars from working out as the men heave; for this purpose there is a small hole bored through the end of every bar to receive the pin: every pin is fastened to the drum-head with a small iron chain; and that the bars may exactly fit their respective holes, they are all numbered.

The pawls, which are on each side, are two short, thick pieces of iron, bolted at one end through the deck to the beams, close to the body of the capstern; the other end, which occasionally turns round on the deck, the pawls being placed in the intervals of the whelps, as the capstern turns, prevents it from recoiling or turning back by any sudden jerk of the cable as the ship pitches, which might greatly endanger the men who heave. And, lastly,

The swifter, is a rope passed through the outer-ends of the bars, and drawn very tight: the intent of this is to keep the men steady as they walk round, when the ship rocks, and to give room for a greater number to assist.

There are commonly two capsterns in a ship of war, the main and the jar capstern; the former of which has two drum-heads, and may be called a double one. This is represented by *fig. 1.* of Plate XXX. the latter is exhibited in *fig. 2.*

Surge

Surge the CAPSTERN, is to slacken the rope heaved round, that it may slide farther upon the body of the capstern, as it would otherwise, by a constant winding round the capstern, get under the whelps, and prevent it from going round. There is generally about two turns and a half of the rope wound about the capstern at once.

Heave the CAPSTERN, is to go round with it, heaving on the bars, and drawing on any rope which creates the purchase.

Come up the CAPSTERN, is to let go the rope on which they had been heaving.

CAPSULATE, or **CAPSULATED PLANTS**, those furnished with capsules for the reception of their seed.

CAPSULE, in a general sense, implies a small receptacle or coffer, in the form of a bag.

The word is formed from the Latin, *capsula*, a diminutive of *capsa*, a coffer.

CAPSULE, among botanists, is a hollow pericarpium or seed-vessel, which cleaves or parts in some determinate manner: it is composed of several elastic valves, which, when the seed is ripe, bursts open, and discharges its contents; and is distinguished from a pod by its form in being short and roundish.

This kind of pericarpium sometimes contains one cell, or cavity, and sometimes more: in the first case it is called an unilocular capsule; in the second, bilocular, trilocular, &c. as it contains two, three, &c. cells or cavities.

CAPSULA-COMMUNIS, in anatomy, is a tunic continuous with the peritoneum, and includes the branches of the vena porta and biliary ducts, both as they approach the liver, and within it.

CAPSULA-CORDIS. See **PERICARDIUM**.

CAPSULÆ ATRABILIARIÆ, called also *glandulæ renales*, and *renes succenturiati*, are two yellowish glands of a compressed figure, lying on each side of the upper-part of the kidneys. They have a very narrow cavity, imbued with a brownish liquor of a sweetish taste. Their figure is irregular, between square, triangular, and oval. Their size also is various; but in adults, they are in general about the bigness of a large nux vomica. In the fœtus they are larger, and often exceed the kidneys themselves in size. The membrane that surrounds them is very thin; it closely involves their whole substance, and connects them with the kidneys. Their blood vessels are sometimes sent from the aorta and the vena cava, but more frequently from the emulgent: their nerves are from the plexus renalis, and their lymphatic vessels are numerous. There is no excretory duct discovered in them; and their use is therefore not certainly known. By their great size in the fœtus, they seem destined rather to the service of that state than of any other.

CAPSULÆ-SEMINALES, the same with *vesiculæ feminales*. See **VESICULÆ**, &c.

CAPTAIN, a military officer, whereof there are various kinds, according to their different departments and commands.

CAPTAIN of a Troop or Company, an inferior officer, who commands a troop of horse or company of foot under a colonel. In the same sense, we say, captain of dragoons, of grenadiers, of marines, of invalids, &c.

In the horse and foot guards, the captains have the rank of colonels.

CAPTAIN General, the officer who superintends the military forces of a kingdom.

CAPTAIN Lieutenant, he, who with the rank of captain, but the pay of lieutenant, commands a troop or company in the name and place of some other person who is dispensed with on account of his quality from performing the functions of his post.

Thus the colonel, being usually captain of the first company of his regiment; that company is commanded by his deputy, under the title of captain-lieutenant.

So in England, as well as in France, the king, queen, dauphin, princes, &c. have usually the title of captains of the guards, gens d'armes, &c. the real duty of which offices is performed by captain-lieutenants.

CAPTAIN Reformed, one who, upon the reduction of the forces, has his commission and company suppressed; yet is continued captain, either as second to another, or without any post or command at all.

CAPTAIN of Militia, he who commands a company of the militia, or trained bands. See the article **MILITIA**.

CAPTAIN BASHAW, or **CAPONDAN BASHAW**, in the polity of the Turks, signifies the Turkish high-admiral. He possesses the third office of the empire, and is invested with the same power at sea, that the vizier has on shore.

CAPTAIN of a Ship of War, the officer who commands a ship of the line of battle, or a frigate which carries twenty guns or above. He ranks with a colonel in the army.

The charge and command of a captain, or commander of one of his Majesty's ships, is very great, various, and complicated, since he is not only answerable for any bad conduct in the military government, navigation, and equipment of the ship, but also for the ill management of his inferior officers, whose particular charges he is appointed to inspect and controul.

When he is informed of the ship's condition, which he is commissioned to govern, he is ordered to attend her constantly, and accelerate the necessary preparations to fit her for sea; indeed so strict are the injunctions laid on him by the lord-high-

admiral,

admiral, or commissioners of the admiralty, in these cases, that he is forbid to lie out of the ship from the day of his arrival aboard, till the day of his discharge, unless by particular leave from the Admiralty or his commander in chief.

He is ordered distinctly to survey all the military stores that are sent aboard, and to return whatever are found unfit for service; to use his utmost assiduity and constant application to procure his complement of men; and observe particularly to enter such men only as are fit for the necessary duty, that the government may be put, as little as possible, to unnecessary expence, and, when fully manned, to endeavour to keep the established number of men complete; in order to this he is ordered to muster them himself, if there be no clerk of the check or muster-master at the port. See those articles.

When employed in a cruising station, he is to keep the sea the full length of time required; but if he is compelled by inevitable necessity from any unforeseen accident to return to port sooner than the limited time, he is to make no unnecessary stay there: at this time he is to be very careful in the choice of a good anchoring situation, and to order the master, or other careful officers, to sound and discover the depths of water, and dangers of the coast.

He is to quarter the officers and men to the necessary places, according to their station and abilities, previous to any engagement; and to exercise them in the discipline of naval war, that they may be the more expert in the time of battle.

He is ordered particularly not to convert any of his Majesty's stores to private uses; nor are any stores to be transferred from their original design, but by the consent of his officers.

He is not to suffer the purser, by any means, to have more advantages, by the provisions of the people, than is consistent with honour, and the general rules of naval discipline.

And, lastly, he is ordered by the admiralty to shew a good example of honour and virtue to the officers and men, and to discountenance and suppress all dissolute, immoral, and disorderly practices; and also such as are contrary to the rules of discipline and obedience, and to correct those who are guilty of the same, according to the usage of the sea. See the article **CHAPLAIN**, to whom this duty is usually transmitted.

He is also instructed to carry no woman to sea, nor request any foreigners, who are officers or gentlemen, to serve in his ship, without orders from the Admiralty: to give timely notice to any merchant-ships, destined on the same road, when going to sea, and take them under his charge and protection, together with such as he meets at sea in his passage, at least as far as his way agrees with theirs. And at the time of his arrival in any port, or his return from abroad, he is to assemble his officers, and

draw up a detail of the observations that have been made during the voyage; or the qualities of the ship, as to her trim, ballast, stowage, and manner of sailing, for the information and direction of those who may succeed in command: and this account is to be signed by himself and officers, and to be returned to the commissioner of the navy residing at the port where the ship is discharged.

CAPTION, in law, is where a commission is executed, and the commissioners subscribe their names to a certificate, declaring when and where the commission was executed. It relates chiefly to commissions, to take answers in chancery, and depositions of witnesses, and take fines of lands, &c.

CAPTIVE, a slave or person taken by the enemy in war, or by a pirate or corsair. See the articles **SLAVE** and **PIRATE**.

CAPTIVITY, a punishment which God inflicted upon the Israelites for their vices and infidelities. The first of these captivities is that of Egypt, from which Moses delivered them; after which are reckoned six during the government of the judges: but the greatest and most remarkable were those of Judah and Israel, which happened under the kings of each of these kingdoms. It is generally believed that the ten tribes of Israel never came back again after their dispersion; and Josephus and St. Jerom are of this opinion: nevertheless, when we examine the writings of the prophets, we find the return of Israel from captivity pointed out in a manner almost as clear as that of the tribes of Benjamin and Judah.

The captivities of Judah are generally reckoned four; the fourth and last of which fell in the year of the world 3416, under Zedekiah; and from this period begin the seventy years captivity, foretold by Jeremiah.

CAPTURE, signifies particularly prizes taken by privateers, in time of war, which are to be divided between the captors. See the article **PRIZE**.

CAPUT, the head, in anatomy. See **HEAD**.

CAPUT CONCUENTIS, a muscle of the neck, otherwise called transversarius secundus. See **TRANSVERSARIUS**.

CAPUT DRACONIS, the dragon's-head, in astronomy, the ascending node of the moon. See the article **NODE**.

CAPUT DRACONIS is also a star of the first magnitude, in the head of the constellation draco. See the article **DRACO**.

CAPUT GALLINAGINIS, in anatomy, a kind of septum, or spongy border at the extremities of the apertures of each of the vesiculæ feminales, serving to hinder the seed coming from one side, from rushing upon, and so stopping the discharge of the other.

Some will have its use to be, to prevent the impulse of the seed from dilating the orifices of the vesiculæ,

vesiculae, and so oozing out, except when assisted by the compression of the surrounding parts, as in copulation; but this, according to others, is rather the office of a distinct caruncle, placed at each orifice, and acting as a valve.

CAPUT MORTUUM, in chemistry, that thick, dry matter, which remains after distillation of any thing, but especially of minerals.

The caput mortuum, called also *terra damnata*, is found in form of a friable, porous matter, without taste or smell: it is ranked among the chemical elements, and supposed to constitute the dry, fixed, earthy, and solid part of all bodies whatever. It is what the chemists call a passive element or principle, serving as the basis or support of the active ones.

CAR, or **CARR**. See the article **CARR**.

CARABE, or **KARABE**, in natural history, a name given to amber. See **AMBER**.

CARABINE, in military affairs, is a sort of musketoon, the barrel of which is rifled spirally from the breech to the mouth, so that when the ball which is forced into it is again driven out by the strength of the powder, it is lengthened about the breadth of a finger, and marked with the rifle of the bore.

The barrel of the carabine is three feet long, and the piece is four feet long, including the stock; it has an iron rammer, and the bullet is first driven into the mouth of the piece with a short iron pin, called a driver, striking it on the end with a small hammer made for that purpose.

The carabine has a much greater range than the fusi, or musket, because the rifle of the barrel impedes the ball, which by that means makes the greater resistance at the first inflammation of the powder, and giving time for the whole charge to take fire before it goes out of the bore, it is at length thrown out with a greater force than from the common musket.

CARABINEERS, or **CARABINIERS**, regiments of light-horse, carrying longer carabines than the rest, and used sometimes on foot.

CARACOL, in the manege, the half turn which a horseman makes, either to the right or left.

In the army, the horse always make a caracol after each discharge, in order to pass to the rear of the squadron.

CARACOL, in architecture, denotes a stair-case in a helix or spiral form.

CARACT, **CARAT**, or **CARRAT**, the name of that weight which expresses the degree of fineness that gold is of.

The mint-master, or custom, have fixed the purity of gold at twenty-four carats; though it is not possible so to purify and refine the metal, but it will want still about one fourth part of a carat in absolute purity and perfection. The carat is

divided into $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, and $\frac{1}{5}$. These degrees serve to distinguish the greater or lesser quantity of alloy therein contained: for instance, gold of twenty-two carats is that which has two parts of silver, or of any other metal, and twenty-two of fine gold.

CARACT is also a certain weight which goldsmiths and jewellers use wherewith to weigh precious stones and pearls.

This carat weighs four grains, but something lighter than the grains of other weights. Each of these grains is subdivided into $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, $\frac{1}{5}$, &c.

CARAGROUTH, in commerce, a silver coin of the empire, weighing nine drachms. It goes at Constantinople for one hundred and twenty aspers. There are four sorts of them, which are all equally current, and of the same value.

CARAITES, in the ecclesiastical history of the Jews, a religious sect among that people, who adhere closely to the text and letter of the scriptures, rejecting the rabbinical interpretations, and the cabala. The Calaites pass for the most learned of the Jewish doctors; they are chiefly to be met with in Poland, Muscovy, and the East; they are but few in comparison of the bulk of the Jews, who are of the party of the rabbins: the latter have so great an aversion for the Caraites, that they will have no alliance, nor even conversation with them: they treat them as bastards; and if a Caraites would turn rabbinist, the other Jews would not receive him.

CARANNA, a concrete resinous juice, exuding from a large tree, of which we have no particular account. It is brought from New Spain, and some other parts of America in little masses, rolled up in leaves of flax; externally of a dark brownish colour, internally brown with a cast of red, variegated with irregular white streaks; somewhat soft and tenacious when it first comes over, but in keeping grows dry and friable.

Caranna has been chiefly employed as an ingredient in vulnerary balsams, corroborant and discutient plaisters, and other external applications. It has very seldom been given internally, and is now, in this country, almost wholly in disuse.

CARAT, or **CARACT**. See the article **CARACT**.

CARAVAN, or **CARAVANNE**, in the East, signifies a company or assembly of travellers and pilgrims, and more particularly of merchants, who for their greater security, and in order to assist each other, march in a body through the deserts, and other dangerous places, which are infested with Arabs, or robbers.

There is a chief, or aga, who commands the caravan, and is attended by a certain number of janizaries, or other militia, according to the countries from whence the caravans set out; which number of soldiers must be sufficient to defend them, and conduct them with safety to the places for which

which they are designed, and on a day appointed. The caravan encamps every evening near such wells, or brooks, as their guides are acquainted with; and there is a strict discipline observed upon this occasion, as in armies in time of war. Their beasts of burden are most commonly camels, who are capable of undergoing a very great fatigue.

CARAVAN is also used for the voyages or campaigns which the knights of Malta are obliged to make at sea against the Turks and corsairs, that they may arrive at the commandments or dignities of the order.

The reason of their being thus called, is because the knights have often seized the caravans going from Alexandria to Constantinople.

CARAVANIER, a person who leads the camels, and other beasts of burden, who are commonly used in the caravans in the East.

CARAVANSERA, or KARAVANSERA, a place appointed for receiving and loading the caravans.

It is commonly a large square building, in the middle of which there is a very spacious court; and under the arches, or piazzas that surround it, there runs a bank, raised some feet above the ground, where the merchants, and those who travel with them in any capacity, take up their lodgings, as well as they can, the beasts of burden being tied to the foot of the bank. Over the gates that lead into the court, there are sometimes little rooms, which the keepers of the caravanseras let out at a very high price, to such as have a mind to be private.

These buildings are chiefly owing to the charity of the Mahometans: they are esteemed sacred dwellings, where it is not permitted to insult any person, or to pillage any of the effects that are deposited there.

CARAVANSERASKIER, the steward or keeper of a caravansera.

He keeps an account of all the merchandizes that are sold upon trust, and demands the payments of the sums due to the merchants for what has been sold in the caravansera, on the seller's paying two per cent.

CARAVAYAY, CARRAWAY, the English name of the carui of botanists. See the article CARUI.

CARAWAY, in botany. See the article CARUM.

CARBUNCLE, in natural history, a very elegant gem, whose colour is a deep red, with an admixture of scarlet.

This gem was known among the ancients by the name of anthrax. It is usually found pure and faultless, and is of the same degree of hardness with the sapphire: it is naturally of an angular figure; and is found adhering, by its base, to a heavy and ferruginous stone of the emery kind: its usual size is near a quarter of an inch in length, and two thirds of that in diameter in its thickest parts: when

held up against the sun it loses its deep tinge, and becomes exactly of the colour of a burning charcoal; whence the propriety of the name which the ancients gave it. It bears the fire unaltered, not parting with its colour, nor becoming at all the paler by it. It is only found in the East-Indies, so far as is yet known, and there but very rarely.

CARBUNCLE, or ANTHRAX, in surgery, an inflammation which arises, in time of the plague, with a vesicle or blister, almost like those produced by burning. This inflammation, for the most part, terminates in a sphacelus, and putrifies the subjacent parts down to the bone, they becoming as black as a coal. A carbuncle always breaks out very speedily, even in the space of an hour or two, attended with heat and pain: as soon as it is opened, it discharges a livid sanies, or sometimes a limpid water: it is black within, which is a sign that the sphacelus has seized the subjacent parts, and is making its progress; but the putrid flesh in those who recover suppurates, and parts from the sound. The size of these pestilential blisters is various, more or less; as is also their number in the patient; for there is no part of the body which they do not infect, and they generally appear in company with buboes.

Those carbuncles which arise in the face, neck, breast, or arm-pits, are observed to be of the worst kind; for they generally kill the patient. As to the internal treatment of carbuncles, the very same is to be observed in this case as has been recommended under the article *pestilential BUBOES*.

In the external treatment, some of the modern physicians use only scarification in this case, with very good success; others only open the eruptions with a pair of scissars, and having discharged the matter, they frequently wash the carbuncle with *sp. vin. campb.* or *sp. vin.* wherein has been digested a little theriaca: they afterwards apply a maturing cataplasm, which is to be continued till the carbuncle separates from the sound parts; then they cut it out all at once.

CARBUNCLE, in heraldry, a charge or bearing, consisting of eight radii, four whereof make a common cross, and the other four a saltier.

Some call these radii buttons, or staves, because round, and enriched with buttons, or pearled like pilgrims staves, and frequently tipped or terminated with flower-de-luces: others blazon them, royal sceptres, placed in saltier, pale and fesse.

CARCASE, in architecture, the shell or ribs of a house, containing the partitions, floors, and rafters, made by carpenters; or it is the timber-work, or as it were the skeleton, of a house, before it is lathed and plastered; it is otherwise called the framing.

CARCASS, in military affairs, is a sort of cartouch for the mortar; its figure is that of a spheroid, lengthened at one end, and flattened at the other; it

is composed of two arches of a circle, or rather an oval, of iron, which intersect each other at right angles, and terminate in a kind of little iron pan, or dish, which forms the flat end of the carcass, and is called its culot or breech.

The interior part of this carcass is filled with grenades, and pistol barrels, charged with leaden balls, as also with pitch, and whole powder, and the whole afterwards covered with okum dipped in pitch, and lacing, which last serves as a wrapper; a hole is made in this cloth, to put such a fuse through into the carcass, as is used in bombs, and the carcass is in the same manner discharged from a mortar.

It is said carcasses were invented towards the year 1672, and used by the French in the wars between France and Holland.

The carcass weighs about twenty pounds, is twelve inches high, and ten inches diameter in the middle. The use of this carcass is to set fire to the places on which it is thrown. The various parts of its composition cannot fail of causing great disorder where it falls; the pitch which is poured into it, so as to fill all the vacancies between the rest of its contents, renders the fire tenacious, and the small barrels it is charged with, and which do not go off all at one time, deter every one from coming near enough to extinguish it, and it is for that reason they are put in. But the use of this kind of fire-ball is notwithstanding abolished, if we may be allowed the expression, because it has been observed that its effect is very little superior to that of a bomb, and that it is notwithstanding attended with a much greater expence.

CARCINOMA, *καρκινωμα*, among physicians, the same with cancer. See the article **CANCER**.

CARDS, among gamesters, little pieces of fine thin pasteboard of an oblong figure, of several sizes, but most commonly in England three inches and an half long, and two and an half broad, on which are painted several points and figures.

The moulds and blocks for making cards are exactly like those that were used for the first books: they lay a sheet of wet or moist paper on the block, which is first slightly done over with a sort of ink made with lamp-black diluted in water, and mixed with some starch to give it a body. They afterwards rub it off with a round list. The court-cards are coloured by means of several patterns, filed stencils: these consist of papers cut through with a pen-knife, and in these apertures they apply severally, the various colours, as red, black, &c. These patterns are painted with oil-colours, that the brushes may not wear them out; and when the pattern is laid on the pasteboard, they slightly pass over it a brush full of colour, which, leaving it within the openings, forms the face or figure of the card.

CARD, among manufacturers, a sort of instru-

ment or comb, composed of a great number of small pieces or teeth of iron wire, incurvated or bent, like a hook, near the middle, and fastened very closely together by the bases or feet in rows.

CARD-MAKING, the business of making cards for the manufacturers.

A piece of thick leather, of the size intended for the card, is strained in a frame for that purpose, and then pricked full of holes, into which the teeth or pieces of iron wire are inserted. After which the leather is nailed by the edges to a flat piece of wood, in the form of an oblong square, about a foot in length, and half a foot in breadth, with a handle placed in the middle of one of the longer sides.

The teeth are made in the following manner: The wire being drawn of the size intended, a skain, or number of wires, are cut into proper lengths, by means of a gauge; and then doubled in a tool contrived for that purpose. After which they are bent into the proper direction by means of another tool, and then placed in the leather, as mentioned above.

CARDAMINE, lady's smock, in botany, a genus of tetradynamious plants, producing cruciform flowers, each consisting of four oval, oblong, open petals, terminating in erect ungues. The fruit is a long compressed cylindrical pod, composed of two spiral valves, with two cells, containing a number of roundish seeds; the common sort grows naturally in the meadows in many parts of England, which being eaten by way of salad in the spring, is supposed to be a good antiscorbutic.

CARDAMOM, in the *Materia Medica*, a dried fruit or pod, brought from the East-Indies; divided internally into three cells, in each of which are contained two rows of triangular seeds, of a brownish colour on the outside and white within. They are distinguished by the epithets *major* and *minor*.

CARDAMOMUM Minor, the lesser cardamom, has short triangular husks, scarce half an inch in length; the produce of a plant with reed-like stalks, and is described in the *Hortus Malabaricus*, under the name of *cleltari*.

These seeds, freed from the husks, are an elegant and useful aromatic, of a grateful smell and flavour, very warm, yet not fiery, or subject, like the spices of the pepper kind, to produce immoderate heat. The husks should be separated only at the time of use; for the seeds soon lose a part of their flavour, in being kept without this defence.

Their virtue is extracted not only by rectified spirit, but almost completely by water also, with this difference, that the watery infusion is cloudy or turbid, the spirituous clear and transparent; the colour of both is a pale yellow. Scarcely any of the aromatic seeds give out so much of their warmth to watery menstrua, or abound so much with gummy matter, which appears to be the principle by

which the aromatic part is made dissoluble in water: the infusion is so mucilaginous, even in a dilute state, as hardly to pass through a filter.

In distillation with water, a considerable quantity of essential oil separates from the watery fluid, of a pale yellowish colour, in smell exactly resembling the cardamoms, and of a very pungent taste: the remaining decoction is disagreeably bitterish, and mucilaginous, retaining nothing of the pungency or warmth, any more than of the peculiar flavour of the spice. On inspissating the tincture made in rectified spirit, a part of the flavour of the cardamoms arises with the spirit, but the greatest part remains behind concentrated in the extract; which smells moderately of the seeds, and has a pungent aromatic taste, very durable in the mouth, and rather more grateful than that of the seeds in substance.

Tinctures of this spice, both in rectified and proof spirit, are more agreeable than the watery infusions; and proof spirit impregnated with its flavour by distillation, more agreeable than the simple distilled water. A tincture of six ounces of the seeds in a quart of proof spirit, and a spirituous water more lightly flavoured with them, by drawing off a gallon of proof spirit from four ounces, are kept in the shops, and occasionally made use of as pleasant warm cordials, and for flavouring other medicines. It is observed, that none of the aromatics answer, in general, so well as the tincture of this spice, for rendering mineral waters and other saline liquors acceptable to the stomach.

CARDAMOMUM *Majus*, the greater cardamom, called also *grana Paradisi*, grains of Paradise. See *GRANA Paradisi*.

CARDIAC, an appellation given to such medicines as preserve, or increase the strength of the heart, and by that means the vital forces, though they do not immediately work upon the heart, nor are particularly appropriated to the corroboration of that part. This effect they perform either by replenishing the exhausted vessels with good humours, or exciting motion when it is required: therefore nutritives duly chosen, with respect to particular constitutions, belong to this class, as well as astringent corroboratives and stimulants. All the modern dispensatories are full of cardiacs or cordials, both of the dry and liquid kind; but the best are those which remove the disorder, of which lowness of spirits is the consequence; and next to these is wine, which administered in proper quantities, and more or less diluted, as circumstances require, will generally answer better purposes than more pompous cordials, whilst it is less capable of doing mischief.

CARDIACA, mother-wort, in botany, whose characters are; it hath a permanent root, from the head of which arises several stalks and leaves; the stalks are quadrangular, and of a reddish black co-

lour; furnished with leaves, placed opposite in pair at each joint on long foot-stalks; the leaves are venous and wrinkled, cut deeply into three sharp-pointed indented segments; the lower ones are larger than those on the stalks. The flower is labiated and monopetalous, with a narrow tube spreading at the brim; the upper lip is cylindrical, long, concave, hairy and obtuse at the point; the lower lip is shorter, reflexed, and divided in three parts. The pistillum arises from the calyx, attended with four embryos, which afterwards become four oblong smooth seeds, inclosed in the empalement; it is found wild on the sides of banks and in lanes in many parts of England.

It is said to cure convulsions, open obstructions of the viscera, and to kill worms, and some account it excellent in diseases of the spleen, and the hysterical passion; the leaves and tops have a moderately strong smell not very agreeable, and a very bitter taste. The dose of the leaves in powder is a dram, and must be taken in wine.

CARDIACUS PLEXUS, in anatomy, a plexus or piece of net-work, formed of a ramification of the par vagum, or eighth pair of nerves.

CARDIALGIA, in physic, a pain at the mouth of the stomach, or heart-burn.

The word is formed from *καρδια*, the heart, or rather the left orifice of the stomach, and *αλγος*, to burn.

The cardialgia is none of the least evils incident to mankind, but of the nature of those disorders which affect the mind as well as the body; nor is it a pain of the heart, as it is commonly reckoned, but of the stomach, which is a very nervous part, and of exquisite sensation, and principally affects its orifices, being seated near the pit of the stomach, and very pungent, attended with great anxiety, difficulty of breathing, loss of strength, restlessness, strainings to vomit, trembling and coldness of the extreme parts, and a slight lipothymy, and owing its original to a convulsion or inflation, and frequently communicating its ill effects, by consent of parts, to the whole nervous system.

The curative intentions are, first to temper and correct the peccant matter lodged about the stomach, and to remove it by proper discutients, or proper evacuants. Secondly, to alleviate and soothe the violent pains, which surprisingly impair the strength, lest an inflammation should succeed. Thirdly, to have a due regard to the primary and original disease, if the disorder be symptomatical. Fourthly, to restore and confirm the tone of the stomach and intestines, which have been weakened by the violence of the pains and spasms, by proper remedies.

The heart-burn is usually caused either by an alkaline or an acid acrimony prevailing in the stomach. If by a redundant acid, which is most generally the case, alkaline substances will cure the

present disorder, as testaceous powders, or a clove chewed in the mouth, and swallowed gradually: but if the disorder proceeds from an alcali, the cure will consist in exhibiting acceftent substances.

Galen recommends vinegar of squills, as a most effectual remedy for preventing the heart-burn: but Hippocrates, in the second of his Epidemics, orders hot bread with pure wine, to be given in this disorder. Perhaps the best medicine yet known for this disease, when it proceeds from an acid acrimony, is the magnesia alba.

CARDINAL, in a general sense, an appellation given to things on account of their pre-eminence: thus we say, cardinal winds, cardinal virtues, &c.

CARDINAL FLOWER, in botany. See the article RAPUNTUM.

CARDINAL VIRTUES, are these four, justice, prudence, temperance, and fortitude, upon which all the rest depend.

CARDINAL POINTS, in cosmography, are the east, west, north, and south. See the article POINT.

CARDINAL WINDS, those that blow from the cardinal points.

CARDINAL SIGNS, in the zodiac, are Aries, Libra, Cancer, and Capricorn.

CARDINAL, an ecclesiastical prince, in the Romish church, being one who has a voice in the conclave at the election of a pope.

The cardinals compose the pope's council, or senate; and there is, in the Vatican, a constitution of pope John, which declares, that as the pope represents Moses, so the cardinals represent the seventy elders. It was pope Pius IV. who first decreed that the pope should be chosen only by the college of cardinals; though some carry up this right as high as Nicolas II. in 1058. The cardinals began to wear the red-hat, at the council of Lyons, in 1243. Till the time of Urban VIII. they were styled only Most Illustrious: afterwards, by a decree of that pope, they had the title of Eminence given them.

The cardinals are divided into six classes, or orders, consisting of six bishops, fifty priests, and fourteen deacons, making in all seventy; which constitute what they call the sacred college. The number of cardinal-bishops has been always the same; but that of cardinal-priests and deacons is not fixed. Till the year 1125, the college consisted of fifty-two or fifty-three. The council of Constance reduced them to twenty-four, and Sixtus IV. raised them again to fifty-three. The six cardinal-bishops are those of Ostia, Porro, Sabina, Palestrina, Frascati, and Albano.

CARDING, the combing and preparing of wool, cotton, flax, &c. with the instruments called cards. See CARDS.

Before wool be carded, it must be greased with

oil, of which one fourth part of the weight of the wool is required, for that which is designed for making the wool of stuffs, and the eighth part for that of the warp.

CARDIROID CURVE, in geometry, a curve first proposed in the Mem. Acad. Scienc. 1705, by Monsieur Carré. It is formed thus: let the diameter AB, (Plate XXX. fig. 3.) of the circle AMBA, revolve about the point A, and AB produced; let B a MN, AD, MN, &c. be always equal to AB, then will the point a describe a curve, which from its figure resembling a heart, is called a cardioid.

From the construction it appears that AN = BA + AM, and that NAN is always double the diameter AB, and is bisected by the circle in M.

If we put AB = a, aE = x, EN = y, the equation of the curve will be expressed algebraically thus, $y^4 - 6ay^3 + 12x^2y^2 - 6ax^3y + x^4 = 12a^2y^2 - 8a^3y + 3a^2x^2$.

For the method of drawing tangents and other properties of this curve, see Phil. Transf. N^o. 461. Sect. 8.

CARDIOSPERMUM, in botany, a genus of octandrious plants, the flower of which consists of four obtuse petals, with eight awl-shaped filaments, topped with small antheræ. The fruit is a roundish inflated trilocular capsule, with three lobes opening at the top, each cell having one or two round seeds marked with a heart. To this genus Linnæus has joined the corindum of Tournefort and vesicaria of Rivini.

CARDO, in anatomy, a name given to the second vertebra of the neck.

CARDUUS, the thistle, in botany, a biennial plant, growing naturally in divers parts of England. This plant sends forth many long leaves near the ground, which are composed of several long segments, placed by pairs, and are joined to a winged border, running on each side of the mid-rib. The whole length of these segments are alternately pointing upwards; the under side of the leaves, and the margin of the mid-rib, are armed with long sharp spines standing every way. The following spring there arises from the center of the plant one strong channeled stalk four or five feet high, branching every way toward the top; the stalk and branches are garnished with the same shaped leaves as below, and each branch is terminated by a single head of purple flowers; each of these are compound, and formed of many hermaphrodite florets, included in a common imbricated ventricose calyx; the florets are monopetalous and funnel-shaped, and contain five short hairy stamina; the germen is oval, and afterwards becomes an oblong, four-cornered seed, crowned with down, and included in the calx.

Another species of the carduus, called in English the lady's thistle, grows wild in many places, and has a long thick fibrous root, and long broad sinu-

ated leaves, crenated on their edges with many hard, shining, smooth, stiff prickles, of a light green colour, and variegated with lines or stripes of white. The stalks come out as the other sort: these are streaked and covered with a hairy down; the tender leaves, after the prickles are taken off, are eaten by some as a salad, and are said to have the same virtues as the *carduus benedictus*; the seeds are excellent for the pleurisy, rheumatism, and pains in the breast, and are given in emulsions.

CARDUUS Benedictus, holy thistle, a plant with rough, narrow, jagged leaves, terminating in soft prickles, and large, hairy, branched stalks, leaning to the ground; on the tops of which grow large, scaly, prickly heads, including a number of yellow florets, which are followed by oblong striated seeds, inclosed in down. It is a native of Spain, and some of the islands of the Archipelago, and sown annually with us in gardens. This plant is classed by Linnaeus with the *CNICUS*, which see.

The virtues of this plant seem to be little attended to in the present practice. The nauseous decoction is sometimes used to excite vomiting, and a strong infusion to promote the operation of other emetics: but this elegant bitter, when extracted from the offensive parts of the herb, may be advantageously applied to other purposes. We have frequently observed excellent effects from a light infusion of *carduus*, in weakness of appetite and indigestion, where the stomach was injured by irregularities, and oppressed by viscid phlegm: nor have we found any one medicine of the bitter kind to fit so easily on weak stomachs, or to heat so little. These infusions, taken freely, promote the natural secretions: drank warm in bed, they commonly increase perspiration, or excite sweat; and as they act with great mildness, not heating or irritating considerably, they have been used, in this intention, in acute as well as chronic diseases.

CARDUUS FULLONUM, a name by which the diapicous, or teazel, is sometimes called. See the article *DIPSACUS*.

CAREENING, in naval affairs, heaving the ship down on one side by a strong purchase applied to her masts, which are properly supported for the occasion, to prevent their breaking with so great a strain.

Careening is used to heave the ship's side so low in the water, that her bottom being elevated above its surface on the other side, may be cleaned of any filth which adheres to it during a long voyage, as shells, ooze, sea-weeds, &c.

This is performed by applying flaming faggots, furze, or other such materials to the bilge; and the fire, thus catching on the tar, pitch, or other stuff, which had formerly been laid on the bottom to preserve it, continues burning till all the excrement is loosened and falls off from the bottom; after this it is covered with a composition of tallow,

fulphur, turpentine, &c. and one side being cleaned in this manner, the other is heaved out for the same purpose. When a ship is laid on a careen, every thing is taken out of her: a ship is also said to careen when she lies down at sea, as pressed with a weight of sail.

CARET, among grammarians, a character marked thus Λ , signifying that something is added on the margin, or interlined, which ought to have come in where the caret stands.

CAREX, in botany, a genus of plants: in the male flower there is no corolla; in the female there are no petals; but the nectarium is of an ovato-oblong form, inflated, bidentated at the top: there is no pericarpium; but the nectarium, growing large, contains a single ovato-acute triquetrous seed, with one of its angles less than the rest.

CARGO, in naval affairs, the merchant-goods whatever sort with which a ship is freighted, and proceeds from port to port.

CARIA, in zoology, a species of ant, common in the East-Indies, and larger than those with us.

They are very mischievous, living in large communities, and throwing up hills of earth five or six feet high.

CARICA, in botany. See the article *PAPAW*.

CARIES, in surgery, is properly a disorder in which the bone, from whatever cause, is deprived of its periosteum; and having lost its natural heat and colour, becomes fatty, yellow, brown, and at length black; this is the first and lightest degree of the disorder, and is what, according to Celsus, the ancients called *os vitiatum*, and the *nigrities ossium*. But the greater degree of this disorder is where the bone is eroded and eaten, and becomes uneven by reason of the number of small holes, of which it is full, when it discharges a filthy sanies, whose acrimony softens, relaxes, and destroys the fleshy parts that grow round it. This is a true caries or ulcer of the bone; and every bone of the body is subject to this disorder: and though this ulcer may appear to be ever so safely or happily healed, yet it too often happens, that after the cicatrix is formed, and has been so for some time, a new abscess will be made, the whole disorder will return afresh, and the acrimonious and corrupted matter, which continually issues out from the various bones, being collected within, will produce many grievous symptoms, and destroy the neighbouring flesh again.

Many methods have been attempted for the cure of a caries; the first and mildest is applied to the slightest degree of the disease, and is performed by the application of spirituous remedies, such as spirit of wine, Hungary-water; or by slight balsamics, such as the powder of birthwort, florentine iris, myrrh, or aloes. Either of these powders is to be sprinkled on the part, after the sanies has been carefully wiped away with dry lint, and this continued till the cure is perfected. In a caries that pene-

trates

trates somewhat deeper, stronger remedies take place, such as powder of euphorbium, or its essence, made in well rectified spirit of wine; or oil of cloves, cinnamon, or guaiacum; either of these may be touched on with a pencil, or laid upon dry lint, and applied: some also use the corrosive medicines, the phagadenic water, and spirit of vitriol, or of sulphur; and, in the place of these, a solution of quick-silver in aquafortis may be used with great success. When by these means an exfoliation of the bone has been produced, the business is then to treat it with balsamics.

A second method of cure for a greater degree of caries is perforating the bone with the trepan, and dressing the part afterwards, either with balsamics, or dry lint. By these means the exfoliation of the bone is forwarded, and new vessels push themselves through the foramina, which, joining with the neighbouring flesh, make a new covering for the bone.

The third method of cure is performed by the raspatory, or chissel, taking off the corrupted or vitiated part of the bone, till all beneath appears white, or ruddy, and sound: and the fourth, which is the most ancient, and the most speedy and certain method, is by the actual cautery, burning down the most vitiated part of the bone. This method, however, is not necessary, except in great degrees of this disorder; and in the performing it, great care must be taken not to injure the neighbouring soft parts. For this reason an assistant should always draw back the lips of the wound both ways, while the operation is performed; and if the opening be not wide enough, it should be previously opened and enlarged by sponge tents, or widened by the knife, till the bone lies fair, when the part must be carefully wiped with dry lint, to cleanse it from the fumes; and if there be any fungous flesh, that must be also removed.

One application of the cautery, when the disorder is considerable, will seldom prove sufficient; it usually requires to be repeated several times, at proper intervals; and if the caries be of such extent that one cautery will not cover it all over, the first must be applied to the middle, and the succeeding towards its edges. This operation is not attended with any great pain, if care be taken not to injure any of the adjacent soft parts; for the bones are in themselves free from any sense of pain. Where the cranium is the seat of this disorder, the cautery is attended with great hazard, as it is also in a caries of the ribs, or sternum, from the neighbourhood of parts of the utmost consequence to life. The carpus and tarsus also will very badly admit of cauterizing, because of the neighbourhood of the tendons and ligaments, which it is scarce possible to avoid injuring in the operation. After cauterizing the part, it is to be dressed with dry

lint only; or if the patient complain of great heat in the part, the lint may dipped in spirit of wine before it is applied: afterwards balsamics are to be applied till the part exfoliate, and then, if the cure be perfect, the vacuity will soon be filled with new found flesh. But if the bone remains bare, or the flesh it is covered with be soft and spongy, and does not adhere sufficiently to the subjacent bone, or where the bone remains discoloured; in either of these cases the cure will not stand, but the disorder will break out again, unless prevented. In these cases therefore the work must be all done over again, the spongy flesh removed, and the actual cautery again applied, otherwise the cure can never stand.

Heister's Surgery.

CARINA properly signifies the keel of a ship. See the article KEEL.

CARINA, in architecture, a name given by the ancient Romans, to all buildings in the form of a ship, from carina, the keel of a ship, as we still use the word nave for *navis*, a ship, the middle or principal vault of our churches, because it has that figure.

CARINA, in anatomy, a term used for the fibrous rudiments or embryo of a chick, appearing in an incubated egg.

The carina consists of the entire vertebrae, as they appear after ten or twelve days incubation.

CARINA, or keel, in botany, the lowest petal of a papilionaceous flower, often bipartite, placed under the vexillum, and between the alae, the lower part of which runs into a claw of the length of the calyx, and inserted in the receptacle.

CARIOUS, something partaking of the nature of a caries. See CARIES.

CARLINA, the Carline thistle, in botany, a genus of syngeneisous plants. The common sort grows naturally upon sterile ground in many parts of England; it hath long, narrow, with deep incisions, and placed in a circle round the root. They are rough and prickly like the other thistles, and of a pale green colour. It hath a compound flower, consisting of many hermaphrodite funnel-shaped florets. The seeds are pappous and downy at top. The root is thick, fibrous, perforated with small holes, reddish on the outside and whitish within; the smell is strong and fragrant, and the taste very penetrating and aromatic; the other species grow in Italy and Germany, and flower in June. Its root is most in esteem, and recommended for its alexipharmic qualities, in resisting infection, and expelling malignities; but the present medical practice takes little or no notice of it.

It is a native of the mountainous parts of Italy and Germany, from whence the dried roots are sometimes brought to us. These are about an inch thick, externally of a rusty or reddish brown colour, internally of a pale yellowish or brownish,

corroded as it were upon the surface, and perforated with small holes, so as to appear, when cut, as if worm-eaten.

The roots of Carline thistle have a moderately strong, not agreeable smell, and a weak, bitterish, subacid, somewhat aromatic taste. They are supposed to be diaphoretic, antihysterical, and anthelmintic. They have been greatly esteemed by foreign physicians, in acute malignant as well as in chronical diseases; and given in substance from a scruple to a dram, and in infusion from one to two drams and more.

CARLINE, or CAROLINE, a silver coin current in the Neapolitan dominions, and worth about four-pence of our money.

CARLINGS, in naval architecture, short pieces of square timber ranging fore and aft, or lengthwise, between the beams of a ship, into which they are scored.

CARMELITES, or WHITE-FRIARS, are an order of our Lady of Mount Carmel, making one of the four orders of mendicants. They pretend to derive their original from the prophets Elijah and Elisha.

CARMINATIVES, in pharmacy, are medicines appropriated to expel wind.

A great many seem to be strangers to this term, as it does not appear to carry in it any thing expressive of the medicinal efficacy of those simples which pass under its denomination. This term had certainly its rise, when medicine was too much in the hands of those jugglers, who, for want of true knowledge in their profession, brought religion into their party; and what through their ignorance they were not able to do by rational prescription, they pretended to effect by invocation and their interest with heaven: which cant being generally, for the surprize sake, couched in some short verses; the word *carmen*, which signifies a verse, was used also to mean an enchantment; which was frequently made use of to satisfy the people of the operation of a medicine they could not account for. And as those medicines now under this name are of quick efficacy, and the consequences thereof, in many instances, surprising; and the most violent pains, sometimes arising from pent-up wind, immediately ceasing upon its dispersion; such medicines as give relief, in this case, are more properly termed carminatives, as if they cured by enchantment.

How they expel wind may be conceived, when we consider that all the parts of the body are perspirable. Sanctorius, in his *Medicina Statica*, determines all we call wind in the bowels, to be such perspirable matter as makes its escape through the coats of the stomach and intestines. Between the several membranes likewise of the muscular parts may such matter break out, and lodge for some time. Now whatsoever will rarely and render such collections of vapour thinner, must conduce

to their utter discharge out of the body; and consequently remove those uneasinesses which arise from their detention. And as all those things that pass under this denomination are warm, and consist of very light subtle parts, it is easy to conceive how a mixture of such particles may agitate and rarefy those flatulencies, so as to facilitate their expulsion; especially considering those grateful sensations which such medicines give to the fibres, which cannot but invigorate their tonic undulations so much, that by degrees the obstructed wind is dislodged, and at last quite expelled: but if the obstruction be not great, the rarefaction of the wind, upon taking such a medicine, is often so sudden, and likewise its discharge, that it goes off like the explosion of gunpowder.

All the things under this class being warm and discutive, are much used in the composition of cathartics, of the rougher sort especially: for the irritation occasioned by those would be scarce tolerable, without the mitigation of such grateful ingredients. Many likewise of this sortment are in the composition of discutive topics.

CARMINE, a beautiful crimson colour, formed of the tinging substance of cochineal, brightened with aqua-fortis by a process similar to that used for dying scarlet in grain. It is of great advantage in painting, as well in water as varnish, both on account of its beauty and standing well; but it will not mix with oil so as to have the due effect in that kind of painting.

The compilers of the new French Encyclopedie have given two or three old recipes for the preparation of this colour; and afterwards recommended another, as preferable to them, taken from Kunkel, which on examination is only a process for making bad lake of scarlet rags: but rather than insert such imperfect instruction for the making an article of great consequence, as may delude those who are earnest in their pursuit of this art into a fruitless expence of time and money, we choose to be silent in this particular, instead of leading them into an error by groundless pretensions to the contrary.

CARNATION, *Dianthus*, in botany, a plant whose flower consists of five petals, whose ungues are longer than the calyx; the cup is a cylindraceous, tubulose, striated, permanent, perianthium, cut at the mouth in five parts; the filaments are awl-shaped, and ten in number; these are the length of the calyx, topped with oval, oblong, compressed antheræ. The germen is oval, and supports two subulate styles longer than the stamina, which are crowned with recurved acuminate stigma; the fruit is a cylindraceous capsule of one cell, which contains a number of compressed angular seeds. These are the characters of the plain single flowers, which among florists are despised, none being acceptable but those which produce double flowers, and

and these are not noticed, except they have peculiar appearances to recommend them. The principal properties in a good carnation are as follow :

1. The stem of the flower should be strong and able to support the weight of the flower, without lopping down. 2. The petals (or leaves) of the flower should be large, broad, stiff, laying flat, without any indentures on their edges; arising from the extremity to the center regularly, so as to form the whole as nearly hemispherical as possible. 3. The pod should be cylindrical, neither too short nor too long, for if it is too short the extreme petals will fall down and much diminish the beauty of the flower, and if too long, the flower will be contracted, which is disagreeable to a curious eye: it is also esteemed a good property if the flower expands without the pod bursting, which it is very apt to do; to remedy which, see the article *BLOWING A Flower*.

4. The colours should be bright, equally striped, on a pure white ground, for if there is one petal single coloured, it is called run, (in the florists language) and despised. The florists class carnations into five orders; the first they call flakes, these are of two colours only, and the stripes are large, going quite through the leaves; the second are called bizars, these have flowers striped or variegated with three or four different colours; the third are called piquees, these flowers should always have a white ground, and are spotted or pounced with different colours; the fourth are called painted ladies, having their petals of a red or purplish colour, striped and are white underneath; the fifth sort are called bursters; these, if managed properly, grow exceeding large, and makes a grand appearance; a kind of secondary pod arises in the middle, which should be carefully taken out when the flower is nearly expanded; this sort is not so much cultivated as formerly, the present taste being chiefly confined to (what the florists call) whole-blowing carnations. Of each of these orders there are numerous varieties, and principally of flakes and bizars, which are most esteemed. To enumerate the varieties of the chief flowers in any one of these orders, would be almost impossible, since every country produces new flowers every year from seeds; so that those flowers, which at their first blowing were greatly valued, are, when become common, little regarded, especially if they are defective in any one property: therefore where flowers are so liable to mutability, either from the fancy of the owner, or that better kinds are yearly produced from seeds, (which it may be remarked does not often happen) they always take place of older, or worse flowers, which are turned out to make room for them. These flowers are dignified with the greatest titles, such as emperors, kings, princes, dukes, dutchesses, earls, countesses, barons, with gentlemen and ladies out of number, which to enumerate (if it were

possible) would require not a small folio. These flowers are propagated either from seeds (by which new flowers are obtained) or from layers, for the increase of those sorts which are worthy of preservation. The seeds should be collected from the best flowers, and sown in the spring in large pots, or boxes, on light, rich earth, and covered about a quarter of an inch with the same. These should be situated where they can receive the morning sun only, observing to water them when necessary. In about a month the plants will come up, which will be fit to transplant in July, taking, if possible, the advantage of moist weather, placing them about three inches distance, in beds of light, rich earth, and kept watered and shaded in sunshine weather, till they have got good rooting. Here they may continue till September, when every other one should be taken up and transplanted into other beds, in order to give room for the remainder; here they may remain till flowering, when the goodness of them may be determined, observing, if the winter proves severe, to cover them occasionally with mats, &c. When they begin to blow, all the single flowers, and those of one colour, should be pulled up, and none but those which are good should be reserved, which, to increase, may be layed down as soon as possible, which is in June or July, according to the condition of the shoots; the method of doing which, see the article *LAYING*.

Florists transplant the layers, when they have got strong roots, into pots, in the size of which at first planting they differ. Some plant them in the large pots they are designed to blow in; others in small pots, which they shift in the spring into larger. This last method appears the most eligible, for if they are in small pots they stand in less compass, and are more easily protected from the severity of the winter; but those who plant them in large ones, shelter them with pots, which are open at the top and made for the purpose, for the cutting winds do them the greatest injury. In these pots are generally placed two plants.

Another method of increasing this plant, is by what is called piping (among florists); the operation is, to cut the shoots quite off through a joint, and sticking them in rich earth, under a glass air tight: with some this practice succeeds very well, but in general it is precarious; however, the plants raised this way commonly spindle higher than those raised by layers.

When carnations begin to spindle, they should be removed on a stage made for the purpose, which generally have cisterns of water round each post; this is necessary, in order to prevent insects, particularly ear-wigs, from getting to the flowers, which if they are suffered to do, will soon destroy them, there being a sweetness at the bottom of the petals which these vermin are very fond of.

Notwithstanding the most valuable flowers are planted

planted in pots, yet there are many planted in borders in the flower-garden, where they are some of its principal ornaments, during their continuance of flower when properly intermixed.

Spanish CARNATION, a name used in the West-Indies, for the poinciana of botanists. See the article POINCIANA.

CARNATION *Colour*, among painters, is understood of all the parts of a picture, in general, which represent flesh, or which are naked and without drapery.

CARNELIAN, *farda*, in natural history, a precious stone, of which there are three kinds, distinguished by three colours, a red, a yellow, and a white. Authors have attributed medicinal virtues to this stone, meaning the red carnelian; this therefore is to be understood the *farda*, or carnelian of the shops. It is very well known among us, and is found in roundish or oval masses, much like our common pebble; and is generally met with between an inch and two or three inches in diameter: it is of a fine, compact, and close texture; of a glossy surface; and, in the several specimens, is of all the degrees of red, from the palest flesh-colour to the deepest blood-red. It is generally free from spots, clouds, or variegations; but sometimes it is veined very beautifully with an extremely pale red, or with white; the veins forming concentric circles, or other less regular figures, about a nucleus, in the manner of those of agates.

The pieces of carnelian which are all of one colour, and perfectly free from veins, are those which our jewellers generally make use of for seals, though the variegated ones are much more beautiful. The carnelian is tolerably hard, and capable of a very good polish: it is not at all affected by acid menstrua; the fire divests it of a part of its colour, and leaves it of a pale red; and a strong and long continued heat will reduce it to a pale dirty grey.

The finest carnelians are those of the East-Indies; but there are very beautiful ones found in the rivers of Silesia and Bohemia; and we have some not despicable ones in England.

CARNIVAL, or CARNAVAL, a time of rejoicing, a season of mirth, observed with great solemnity by the Italians, particularly at Venice, holding from Twelfth-day till Lent.

CARNIVEROUS, an appellation given to animals which naturally feed on flesh, and thence called beasts or birds of prey.

The word is compounded of the Latin, *caro*, flesh, and *voro*, to devour.

CARNOSITY, a term sometimes used for an excrescence, or tubercle, in the urethra.

CARO MUSCULOSA QUADRATA, in anatomy, the same with the palmaris brevis. See the article PALMARIS.

CAROB-TREE, in botany. See the article CERATONICA.

CAROLOSTADIANS, in church history, an ancient branch of Lutherans, who denied the real presence in the eucharist. See the article EUCHARIST.

CAROLUS, an ancient English broad piece of gold, struck under Charles I. Its value has of late been at twenty-three shillings sterling, though at the time it was coined, it is said to have been rated at twenty shillings.

CAROLUS, a small copper coin, with a little silver mixed with it, struck under Charles VIII. of France.

The carolus was worth twelve deniers, when it ceased to be current.

Those which are still current in trade, in Lorraine, or in some neighbouring provinces, go under the name of French fols.

CAROTEEL, in commerce, an uncertain weight or quantity of goods: thus a caroteel of cloves is from four to five hundred weight; of currants, from five to nine; of mace, about three hundred; of nutmegs, from six to seven hundred and a half.

CAROTIDS, in anatomy, two arteries of the neck, which convey the blood from the aorta to the brain, one called the right carotid, and the other the left: they arise near each other, from the curvature of the aorta, and run upon each side of the arteria trachea, between it and the internal jugular vein, as big as the larynx, without any ramification; each of these is then ramified into two branches, one named internal, the other external. The internal carotid artery having passed the great canal of the apophysis petrosa of the os temporis, sends off a branch through the sphenoidal fissure, to the orbit of the eye, and soon afterwards another through the foramen opticum, by which it communicates with the external carotid. The external is the smallest; it runs between the external angle of the lower jaw, and the parotid gland; afterwards it ascends on the fore-side of the ear, and ends in the temples. All the ramifications of the carotids are covered by the pia mater, in the duplicature of which they are distributed, and form capillary, reticular textures, in great numbers; afterwards they are lost in the inner substance of the brain. See the article ARTERY.

CARUCAGE, or CARUAGE, a term in husbandry for the ploughing of ground, either ordinary, for grain, hemp, and flax; or extraordinary, for woad, dyers-weed, rape, &c.

CARP, in ichthyology, the English name of the cyprinus, with four cirri, or beards, and the third ray of the back-fins armed with small hooks.

CARPENTER, an artificer in wood, designed for the purposes of building.

Ship CARPENTER, an officer appointed to examine

examine into the condition of the ship's hull and masts ; and to keep the pumps in good order, which he is frequently ordered to examine : he is likewise to observe that the ships decks and sides are well caulked, and whether any thing gives way. It is also his duty, in the time of battle, to watch up and down in the lower apartments of the ship, to stop any holes that may have been made by balls in the sides, with shot-plugs : and likewise to fish, or otherwise secure the masts and yards.

As the carpenter and boatswain (who generally mess together) are distinguished, by their singular qualities, from the rest of the sea-officers in general, so are they from one another in particular : for at the same time that the latter is remarkable for a savage tone of voice, the former is equally characterized by a groveling inclination of his head, partly occasioned by carrying every day at noon a large quantity of useful timber out of the king's yards, which he was dextrous enough to convert into small pieces, and call his chips, and partly by not having been taught to dance till he was instructed by the sea-school-master ; who likewise taught him the use of Gunter's scale, since which time he has for ever distracted the boatswain with talking about the square and cube-roots.

The carpenter is generally possessed of a very crooked and perturbed spirit, owing certainly to having been pestered with a variety of knotty impediments, which greatly incumbered him, and at length made his temper as fowery as the purser's petty-warrant beer.

CARPENTRY, the art of cutting, framing, and joining large pieces of wood for the use of building. It is one of the arts subservient to architecture, and is divided into house-carpentry and ship-carpentry : the first is employed in raising, roofing, flooring of houses, &c. and the second in the building of ships, &c. The rules in carpentry are much the same with those of joinery ; the only difference is, that carpentry is used in the larger coarser work, and joinery in the smaller and curious. See **JOINERY**.

CARPET, a sort of covering of stuff, or other materials, wrought with the needle or in a loom, forming part of the furniture of a house, and is commonly spread over tables, or laid upon the floor.

Persian or Turkey carpets are those most esteemed ; though at Paris there is a manufactory after the manner of Persia, where they make them little inferior, not to say finer, than the true Persian carpets. They are velvety, and perfectly imitate the carpets which come from the Levant. There are also carpets of Germany, some of which are made of woollen stuffs, as serges, &c. and called square carpets : others are made of wool also, but wrought with the needle, and often embellished with silk ; and lastly, there are carpets made of dog's hair. We have likewise

carpets made in England equal to any brought from the East.

CARPINUS, horn-beam, in botany. See the article **HORNBEAM**.

CARPOBALSAM, in the materia medica, the fruit of the tree which yields the true oriental balsam.

The carpobalsam is used in Egypt, according to Prosper Alpinus, in all the intentions for which the balsam itself is applied : but the only use the Europeans make of it is in Venice-treacle and mithridate, and in these not a great deal ; for cubeb and juniper berries are generally substituted in its place.

CARPOCRATIANS, heretics who sprung up towards the middle of the second century, being a branch of the ancient Gnostics. They held a community of wives ; and maintained, that a man cannot arrive at perfection without having passed through all criminal actions ; laying down as a maxim, that there is no action bad in itself, but only from the opinion of men ; accordingly they are charged with committing the most infamous at their love-feasts. They attributed the creation of the world to angels ; they said that Jesus was born in a manner like other men ; they rejected the resurrection of the body ; and marked their disciples at the bottom of the right ear with a hot iron, or with a razor.

CARPUS, the wrist, in anatomy. See the article **WRIST**.

CARR, among the ancients, a kind of throne mounted on wheels, and used in triumphs and other solemn occasions.

CARRAC, the name of the vessels employed by the Portuguese in the East-India and Brazilian trade ; they are very large, and fitted for fighting as well as for burden.

CARRAT, or **CARACT**. See **CARACT**.

CARRIAGE, a mechanical vehicle for conveying, persons, goods, or matter of what kind soever from one place to another.

Their constructions and forms are different, according to the purpose for which they are required. If for land-carriage, the machines chiefly used in Europe are coaches, chariots, calashes, berlins, waggon, with four wheels ; chaises, carts, and drays, with two wheels, all drawn by oxen, horses, mules, buffaloes, &c. But those for water-carriage in general are ships, barks, boats, &c. For the nature and construction of each, see their respective name.

Letter or Bill of CARRIAGE, a writing given to a carrier or the master of any carriage, containing the number and quality of the pieces, bales, &c. of merchandizes, which he is entrusted with, that he may demand the payment of the carriage, and that the person to whom they are addressed may see whether they are delivered in the same number, and in as good condition as they were given to the carrier.

CARRIAGE of a cannon, is a sort of cart or dray, (see Plate XXVII. fig. 3.) composed of two

long pieces of wood, called sides, or cheeks, which are made in a bending form, so that, (Plate XXVII. fig. 4.) one end of them *b* rests on the ground, and the other *a* is supported by the axis or axle-tree of the wheels, from which it jets out about a foot. The cheeks are joined to each other by four pieces of wood, called cross-quarters or transoms; the first *a* is called the transom of the chace; the second *c* the transom of the bed; the third *d* the transom of the sight; and the fourth *g*, which fills all the space between those parts of the cheeks that rest on the ground, is called the transom of the lunet, or eye-hole. In the cheeks, between the part that is opposite to the transom of the chace, and that which is opposite to the axle-tree of the wheels of the carriage, are two semicircular notches, in which the trunnions of the cannon are placed; on the three first transoms *a c d* is placed a piece of wood of a proper thickness, on which the breech of the cannon rests; this plank is called the bed of the carriage.

When the cannon is to be carried into the field, or removed from one place to another, the limber (avaunt-train) or fore-carriage, is added to that part of the cheeks where the transom of the lunette is placed.

Besides the carriage now described, which is the most common, and called the wheel-carriage, there are fort-carriages, sea-carriages, and baltard-carriages, which have low solid wheels, that serve to move them on a rampart, or to and fro in other places of small extent.

CARRIAGE, in agriculture, a furrow for the conveyance of water to overflow and improve the ground. It is distinguished into two sorts; the main carriage, which should be made a convenient descent; and the lesser carriages, which should be shallow, and as many in number as possible.

CARROT, *Daucus*, in botany, a genus of pentandrious plants, producing umbelliferous flowers. The principal umbel hath an involucreum, which is polyphyllous and pinnated. The proper flowers consist each of five inflexed heart-shaped petals, and contain five capillary stamina. The germen supports two reflexed styles, topped with obuse stigma, and becomes afterward a small roundish striated fruit, divided in two parts, each having a single seed, convex and furrowed on one side, and plain on the other.

The common manured carrot hath leaves divided into a number of narrow segments; and the root, which is fleshy, is so well known that it requires no description. This plant is propagated by seed, and delights in a warm, light, sandy soil, which should be pretty deep, and well worked, that the roots may more easily run down; for if they meet with any obstruction, they are very apt to grow forked, and shoot out lateral branches, especially where the

ground is too much dunged the same year that the seeds are sown; therefore the properest land for carrots is ground that has been well dunged, and cropped at least a year before; (this is in respect to kitchen-gardens;) but where the soil is fresh and fitting for carrots, dunging is not necessary.

Carrots are sown at different times of the year, in order to be fit for use at various seasons: the first season is about Christmas, on warm borders, &c. The second is in February or March: this is designed for the principal crop. For a third or autumnal crop, June or July is the time; and at the end of August some may be sown, in order to stand the winter, by which method there may be produced early carrots in March following, before the spring sowing is fit to draw. Previous to sowing the seeds, they should be well rubbed in the hands, to prevent their adhering together, which they are apt to do by forked hairs on their borders: and at the time for sowing, a calm day should be chosen for the operation; for they being very light, it would be a difficulty to sow even, if the wind blew strong. When the seed is sown, they should be trod into the ground, and afterward raked smooth.

When the plants are come up, they should be hoed out singly, at the distance of four inches. This is absolutely necessary, as it not only destroys the weeds, but also gives the plants which are left good encouragement to grow.

The roots of carrots have been long cultivated in gardens for culinary uses; but has not till of late years been much cultivated in the fields for cattle; we shall therefore subjoin the following extract, from a pamphlet lately published by Mr. Robert Billing, farmer at Weasenham, in Norfolk, by desire of the society for the encouragement of arts, manufactures, and commerce at London.

Mr. Billing says, that the culture of carrots for the winter feed of cattle has been long practised in the eastern parts of Suffolk; but never in the county of Norfolk, where turnips has hitherto been preferred. The premium offered by the society of arts encouraged him to make trial of them in the latter county, and in 1763, he sowed thirty acres and a half in three fields; one of thirteen acres, one of half an acre, and one of seventeen acres. The piece of thirteen acres was a cold, loamy soil, shallow, and underneath it a loamy gravel; the half acre a mixed soil upon a moist clay; and the seventeen acres a light dry soil, newly improved with a marle, fourteen acres of which were a shallow black sand upon a kind of imperfect grit-stone, called in that county carr-stone.

Mr. Billing advises plowing the land for carrots early, before the winter begin, that the ground may have all the benefit of the frost for mellowing the soil, and fitting it in the spring for the reception of the seed. The ground for carrots, every body knows, cannot be made too fine.

He sowed four pounds of seed upon an acre, in the same manner as turnip seed is sowed, only passing it first through a fine chaff sieve, to make it separate.

He recommends late sowing as a means of checking the weeds and lessening the expence of hoeing; for as carrots lie long in the ground before coming up, the weeds are apt to get the better of them; but this seems to have little weight, the land being well cleaned, early sowing, in March, is most undoubtedly the most proper season; and every man's experience must direct him in the hoeing of them. He owns, that harrowing the weeds out, after the carrots come up, will not hurt the carrots.

Of the carrots on the thirteen acres, many, when dug up, measured two feet long, and from twelve to fourteen inches round, at the upper end. These were sown on wheat stubble, danged the year before; the half acre was clover laye danged for the carrots, and there they grew considerably bigger. This thirteen acres and a half produced two hundred and forty cart loads of carrots; and the seventeen acres about two hundred and seventy loads, in all five hundred and ten; equal in use and effect to near one thousand loads of turnips, or three hundred loads of hay, as experience has evinced, by the various ways in which they have been tried.

The season for drawing the carrots is a little after Michaelmas. Mr. Billing says, that the best way of drawing them is by a man with a four pronged fork, who breaks the ground about six inches deep, and a little boy follows him to pick them up; but this method being tedious in large plantations, he found it necessary to plow them up with a narrow-sheared wheel plow, which going slow, turned them up without injury to the carrots; and the cattle, being put into the field, eat them up without waste; the first plowing does not throw them all up: but those thrown up by a second and third plowing, are equally good with those thrown up at first.

With this crop of carrots Mr. Billing fattened thirty-three neat beasts, and forty-nine shearing weathers. At first, he gave the cattle with the carrots a mixture of cabbages, forty load of which grew on half an acre of arable. This forty load of cabbages he computes to be equal to eighteen loads of carrots; the cattle were fonder of these at first, but having gradually taken to eat the carrots, they soon preferred them. To the thirty-three neat beasts, and forty-nine weathers, he allowed one load of turnips when his cabbages were spent, and three loads of carrots each day, and they fattened as fast upon these as upon seven loads of turnips, as experience taught him. He computes the profits of this small stock to be about one hundred and twenty pound.

He also fed sixteen working horses with these carrots, without hay or corn, during the winter,

except when they carried corn to Brancaster, at sixteen miles distance, and to the team employed in this service, he allowed only a bushel of oats a day. Pease-straw, chaff, and carrots yielded all their ordinary food. For the horses, Mr. Billing had the carrots washed, their heads and tails chopped off, which served the hogs, and sometimes they had a cut or two besides. The sixteen horses eat two loads of carrots a week, equal to more than a load of hay.

Mr. Billing has not given us exact an account, as might be wished, of the manner of drawing his carrots, and feeding his cattle, though the omission does not proceed from design, but inadvertency. It should seem, that at first he pulled up his carrots, by a man and a boy, carried them to a feeding close, and dispersed them about for the cattle to pick up; but afterwards, finding perhaps, this way tedious, he made use of his plow, turned his cattle into the same field where the carrots grew, and left them to pick them up, dirty as they were, for their own subsistence. This seems to be implied, but here we are not told what quantity of ground he plowed up at a time; whether more than the cattle eat in a day; or whether those the horses eat were plowed up fresh, or whether he had any method of keeping them for future use after being dug or plowed up. It should seem by some expressions indeed, that he suffered them to continue in the ground all the winter, as, he says, they were difficult to be dug up, during a hard frost; but if carrots will keep without damage during the winter, it were easy to preserve a quantity to provide against the rigour of frosts, or other accidents, by the following method: about the beginning of November, when the green leaves are decayed, they should be dug up, and laid in sand, in a dry place, where the frost cannot come at them; and take them out from time to time occasionally as they are wanted.

Some of the largest and straightest roots may be reserved for seed, which may be planted in the middle of February, at about a foot distance; and in August the seeds will be ripe, when they should be cut, and kept in a dry place till wanted.

Botanists enumerate six other species of carrot; some of them are reserved by the curious for the sake of variety. The common wild carrot grows in many parts of England: the seeds of this sort are used in medicine. It is esteemed as a diuretic, and good against the stone and gravel: it is also useful in uterine and hysterical disorders.

Another sort, called candy carrot, the seed of which is long and slender at both ends, swelling at the middle, of a pleasant smell, and sharp hot taste. It grew originally in Candia, and other places in the Levant. The seeds only are used, being aperient and good in disorders of the kidneys. It is likewise accounted a good alexipharmic, and proper against the bites of venomous creatures; whence it is an ingre-

ingredient in mithridate and Venice-treacle. This lait is a species of the athamanta. See the article SPIGNEL.

CARROUSAL, a course of chariots and horses, or a magnificent entertainment exhibited by princes on some public rejoicing. It consists in a cavalcade of several gentlemen richly dressed and equipped, after the manner of ancient cavaliers, divided into squadrons, meeting in some public place, and practising juffs, tournaments, &c.

CART, a vehicle, mounted upon two wheels, drawn by one or more horses, used for the carriage of various sorts of heavy things. The word seems derived from the French *charrette*, which signifies the same; or rather the Latin *carreta*, a diminutive of *carrus*.

A cart differs from a wain in that the former is drawn by horses, and has two sides called trills or shafts; whereas the latter is drawn by oxen, and has a wain-cope.

Carts in London and Westminster are not to carry more than twelve facks of meal, or one chaldron of coals, on pain of forfeiting one of the horses. The wheels are to be of a certain thickness, without iron; and if any person ride in a cart, not having another to guide it, he shall forfeit ten shillings. The chief difficulty in constructing of wheel carriages, is properly fitting the wheels and axle, which ought to be done in such a manner that the carriage may move with the least power possible; but by the present construction of many wheel carriages, one would imagine they intended their cattle to draw by the ears or tail, instead of the proper place. See WHEEL-CARRIAGES, and WAGON.

CARTEL, in the marine, a ship provided in time of war to exchange the prisoners of any two hostile powers; also to carry any particular request or proposal from the one to the other: for this reason, she is particularly commanded to carry no cargo or arms, only a single gun for firing signals.

Our honest Americans, however, who have so forely grieved of late for paying a small part of the great taxes of this country, although demanded for their own particular protection, made not only no scruple to disobey and despise this regulation of cartels during the late war; but, on the contrary, gave continual supplies of provisions to our enemies in the West-Indies, and thereby recovered them and recruited their fallen spirits, at a time when they were gasping under the weight of our arms. With so much address, indeed, did these oppressed and unfortunate traders conduct this scheme, that ten or twelve cartels being laden at the same time with beef, pork, bread, flour, &c. sailed together for the French islands, and, in order to evade the strict examination of our ships of war, were provided with a guardian privateer, equipped by the same expert owners, to seize their own vessels, and direct

their course to the places of their first destination; but if they were examined by our ships of war, to an English port. But this clumsy trick did not long escape the vigilance of our naval-officers, who found that the fellows sent abroad by way of commanders or prize-masters were utterly ignorant, and incapable of piloting any ship; and of consequence only sent to elude their scrutiny.

The most bare-faced piece of effrontery however that was ever committed of this kind was the seizing an armed vessel, fitted in Philadelphia, to take these illegal cartels. She was commanded by a gentleman, whom the majority of the merchants in that city joined to oppose and distress. They employed a crew of ruffians, who seized his vessel openly in the most unwarranted and lawless manner, and brought her up in triumph to the town, when she had only five men aboard: and so inveterate was their hatred to the commander, that he was obliged to leave the country precipitately, as being in danger of his life.

CARTEL signifies also a letter of defiance, or a challenge, to decide a controversy, either in a tournament, or in a single combat. See the article DUEL.

CARTESIAN Philosophy, the system of physics advanced by Des Cartes, and maintained by his disciples the Cartesians.

M. Des Cartes, in order to account for the celestial appearances, supposes that the matter of the world was at first divided by the Almighty into innumerable little equal parts, each endued with an equal degree of motion, both about its own center, and separately, in such a manner, that this matter constituted a fluid. He also supposed, that several collections of this matter were endued with a motion about different points, as common centers; which points were placed at equal distances, in such a manner, that the matter round them constituted different vortices, as he calls them. He farther supposed, that the first particles of matter became, by those intestine motions, of a spherical figure, and consequently composed globules of several magnitudes; and these he calls the matter of his second element.

But the very small particles which were rubbed off by the aforesaid motions, from the first particles of matter; and driven violently many different ways, made up a new matter, which he calls his first element. And since there would be more of his first element than was sufficient to fill the vacuities between the globules of the second element, he supposes that the remaining part would be driven towards the centre, by the circular motion of these globules, which did, for that reason, recede from it: and this matter, being there amassed in a sphere, would, in the centre of every vortex, produce a body like the sun; which sun being thus formed, and moving about its own axis, with the common matter of the vortex, would necessarily throw out some parts of its matter, through the vacuities of the globules of the second element,

element, constituting the vortex; and this especially, at such places as are the farthest from its poles, receiving at the same time, by these poles, as much as it loses in its equatorial parts; and by this means it would be able to carry round with it those globules that are nearest with greater velocity, and those that are remote with less: so that those globules, which are nearest the centre of the sun, must be least; because, were they greater or equal, they would, by reason of their velocity, have a greater centrifugal force, and recede from the centre. And should it happen that any of these sun-like bodies in the centers of the several vortices should be so incrustated and weakened, as to be carried about the vortex of the true sun; should it happen to be of less solidity, or less motion, than the globules towards the extremity of the solar vortex, it would descend towards the sun, till it met with globules of the same solidity, and capable of the same degree of motion with itself; and being fixed there, it would for ever after be carried about by the motion of the vortex, without either approaching any nearer to, or receding farther from the sun; and so become a planet.

Supposing all this, we are next to imagine that our system was at first divided into several vortices, in the centre of each of which was a lucid spherical body; and that some of these, being gradually incrustated, were swallowed up by others, which were larger and more powerful, till at last they were all destroyed and swallowed up by the biggest solar vortex, except some few, which were thrown off in right-lines, from one vortex to another; and so became comets: and from hence it appears, that those planets which are nearest the sun, are less solid; and that is also Des Cartes's reason why we see always the same face of the moon; because the hemisphere, which is opposite to the sun and the earth, is somewhat more solid than the other; as also, because the matter of the first element, which makes up the body of the sun, moves with a greater velocity in the parts of the vortex, and the bodies swimming in it, than those that are remoter: therefore those planets which are nearer to the sun, must finish their periods sooner than those which are more remote from him. And the reason why the planets revolve round their axis is, because, according to this hypothesis, they were lucid, sun-like, and revolving bodies before.

Yet, notwithstanding all this fine chimera, it is; Certain, that a vortex, produced by the revolution of a sphere about its axis, must be propagated in infinitum, if nothing hinder it: and therefore, since there must be as many vortices as there are fixed stars, one vortex would certainly run into another, and every particle would be actuated by a motion compounded of that of all the central spheres; which is absurd, and contrary to that constancy, limitation, and uniformity, which is observed in the phenomena of the heavenly bodies.

2. Since the motion of the parts of the vortices nearest the centre is swifter than that of the more remote, they must press upon the exterior parts, and thereby perpetually impart something of their motion to them; and therefore those exterior parts of the vortex will be continually lessening some part of their motion, which being never restored, these parts must still move slower and slower, till at last all the motion will be quite destroyed.

3. According to this hypothesis, each planet is of the same density with the parts of the vortex in which it swims, being governed by the same laws of motion, and is, as it were, only some concreted parts of the vortex. But the times of the periodical motion of bodies, carried round by a vortex, are in a duplicate ratio of their distances from their centre; as Sir Isaac Newton hath demonstrated in Sect. IX. of his Principia. Whereas the squares of the times of the periodical revolutions of the planets are as the cubes of their mean distance from the centre, or from the sun: wherefore the planets cannot be carried round by a vortex.

4. If a vortex run out in infinitum, then would a body carried round by it certainly describe a perfect circle, unless something solid hindered it; and therefore the greater the distance between those solid bounds, or the larger the basin be which contains the vortex, in respect of the orbit of the body carried round in it, the nearer would this orbit be to a circle; that is, the excentricity of the planets nearest the sun would be less than that of those which are more remote. Whereas the direct contrary to this is true in fact, the excentricity of Mercury being greater than that of Saturn.

5. A body, carried round in a vortex of the same density with it, would necessarily describe a circle, to whose plane the axis of the central body, producing the circulation of the fluid, would be perpendicular: and yet there is not one planet to the plane of whose orbit the sun's axis is perpendicular.

6. The comets have their orbits, not only oblique to, but sometimes at right angles with, the plane of the ecliptic; sometimes the course of these comets is diametrically opposite to that of the sun: they persevere in their motion, without any change. By lines drawn from them to the sun, they describe equal areas in equal times; and sometimes they enter into the vortex of the sun. All which would be impossible, if the solar vortex moved round forcibly enough to carry these vast bodies of the planet along with it.

CARTHAMUS, bastard saffron, in botany, a genus of plants whose flower is composed of several hermaphrodite florets, each of which are monopetalous, and funnel-shaped; and contain five short capillary filaments, topped with cylindrical, tubulose antheræ: it is destitute of a pericarpium; but the calyx incloses a single, oblong, angular seed.

There are several species of carthamus; but the
6 K common

der the name of antophyllus, is marked on the top with the remains of the flower; it about the size and shape of an olive, and contains, under a thin blackish shell, a hard kernel of the same colour, which has a deep longitudinal seam on one side. The cloves are said to be cured by exposing them to smoke, and afterwards drying them in the sun.

The clove has a strong agreeable smell, and a bitterish, hot, very pungent taste: it is one of the hottest and most acrid of the substances of the aromatic class, and as such is often used, not only internally, but as an external stimulant. The antophyllus has the same kind of flavour with the clove itself; but being far weaker in smell as well as in taste, it is very rarely applied to any medicinal purposes, and is now scarcely ever to be met with in the shops.

The clove is remarkably disposed to imbibe humidity; and when robbed of its active parts, by infusion in menstrua or distillation, and afterwards mixed with fresh cloves, it regains from them a considerable share both of taste and smell. The Dutch, through whose hands this spice is brought to us, have often practised this abuse; which, however, may be easily discovered; for those cloves which have once lost their virtue, continue always not only weaker than the rest, but likewise of a much paler colour.

Tinctures of cloves in rectified spirit, are of a dark reddish brown colour, of no great smell, but of a highly acrid taste: if the quantity of spirit be considerable, it leaves the clove deprived of all its virtue. On inspissating the filtered tincture, the spirit which distils, is found to have very little impregnation from the spice: the remaining extract, nevertheless, does not discover so much smell as the clove in substance, but its taste is excessively pungent and fiery. The quantity of this burning extract amounts to about one-third the weight of the clove.

Digested or infused in water, they impregnate the liquor more strongly with their smell than they do spirit, but not near so much with their taste: after repeated infusion in water, they impart still a considerable tincture to rectified spirit. In distillation with water, they give over, very slowly, near one-sixth their weight of essential oil; when carefully distilled, colourless; by age, changing to a yellow, and at length to a reddish brown colour; when drawn with a strong fire, proving often of this colour at first; smelling strongly of the cloves; but in taste only moderately pungent, much less so than the spirituous extract. Neither the remaining clove nor decoction have any considerable taste; the pungency of this spice seeming to depend, not on the volatile or fixed parts separately, but on the combination of the two.

CARYOPHYLLUS *Ruber*, the clove July-flower, or gilli-flower, in botany, is the name of a plant

with many smooth, round, jointed-stalks, and grassy leaves of a bluish-green colour, standing in pairs at the joints: the flower is composed of five petals, narrow at the bases, broad and jagged at the top, set in an oblong cylindrical cup, which is covered at the bottom with four short scales, forming as it were a secondary cup: after the flower has fallen, the calyx becomes a covering to a number of small, flat, wrinkled, black seeds. It is perennial, and said to have been a native of Italy.

Several varieties of these flowers are cultivated in gardens; but the sort principally used in medicine are of a deep crimson colour, and of a pleasant aromatic smell, somewhat resembling that of the clove described in the preceding article. They are chiefly valued for the fine smell, which is readily extracted by infusion in water, and dissipated even by light coction. Three pounds of the fresh flowers, clipped from their heels, communicate, by infusion in a close vessel for a night, a grateful and moderately strong smell, and a deep red colour, to eight or nine pints of water; which, with a proper quantity of fine sugar, forms a very agreeable syrup.

On distilling the fresh flowers with water, the distilled liquor proves considerably impregnated with their fragrance. Rectified spirit, digested on the flowers, receives a much paler tincture than the watery liquors, but extracts the whole of their active matter. In distillation the spirit elevates much less than the water.

CARYOTA, in botany, a genus of plants; the male and female flowers of which are produced in separate parts of the same spadix; the corolla is divided into three hollow, lanceolated segments; the stamina are numerous filaments, longer than the corolla; the antheræ are linear; the corolla in the female flower is divided into two very small acuminate segments; the fruit is a round berry, containing a single cell; the seeds are two, large, oblong, rounded on one side, and flattened on the other.

CASCABLE, the knob or button at the end of the breech of a cannon. See the article **CANNON**.

CASCADE, a steep fall of water from a higher into a lower place.

CASCANS, in fortification, holes in form of wells, serving as entries to galleries to give vent to the enemies mines.

CASCARILLA, or **ELEUTHERIA**. See the article **ELEUTHERIA**.

CASE, *Casus*, among grammarians, implies the different inflexions or terminations of nouns, serving to express the different relations they bear to each other, and to the things they represent.

There is great diversity among grammarians, with regard to the nature and number of cases; they generally find six, even in most of the modern lan-

languages, which they call the nominative, genitive, dative, accusative, vocative, and ablative; but this seems in compliance with their own ideas of the Greek and Latin, which they transfer to their own languages. The termination is not the sole criterion of a case; for though some authors reckon five cases of nouns in the Greek, and fix in the Latin, yet several of these cases are frequently alike: as the genitive and dative singular of the first and fifth declensions of the Latin; the dative and ablative plural of all the declensions, &c. the genitive and dative dual of the Greek, &c.

The English and many other modern languages express the various relations, not by changes in the terminations, as the ancients, but by the apposition of articles; it is certainly wrong to say, that *of a father* is the genitive case of *father*, and to a *father* the dative; for *of* and *to* are no part of the word *father*, they are only articles or modifications, which shew the different relation of the word *father*.

CASE, among printers, denotes a sloping frame, divided into several compartments, containing a number of types or letters of the same kind.

From these compartments the compositor takes out each letter as he wants it, to compose a page or form. Thus they say a case of Pica, of Greek, &c.

CASE-HARDENING, a method of preparing iron, so as to render its outer surface hard, and capable of resisting any edged tool.

This is a lesser degree of steel-making, and is practised by baking, calcination, or cementation in an oven, or other close vessel, stratified with charcoal and powdered hoofs and horns of animals, so as to exclude the air. See **STEEL**.

CASE-SHOT, in the military art, musket-ball, stones, old iron, &c. put into cases, and shot out of great guns.

CASEMATE, or **CAZEMATE**, in fortification. See the article **CAZEMATE**.

CASEMENT, or **CASEMATE**, in architecture, a hollow moulding, which some architects make one-sixth of a circle, and others one-fourth.

Casement is likewise the name of that part of the window hung with hinges, and which opens in the same manner as a door, before the invention of sashes, and still to be found in most antique buildings.

CASERN, in fortification, lodgings built in garriſon-towns, generally near the rampart, or in the waste places of the town, for lodging the soldiers of the garriſon.

There are usually two beds in each casern for fix soldiers to lie, who mount the guard alternately; the third part being always on duty.

CASES RESERVED, in the polity of the Roman church, atrocious crimes, the absolution of which is referred by the superiors to themselves or their vicars.

CASH, in the commercial style, denotes the stock

of money any merchant, trader, or banker has at his disposal, in order to trade.

CASH-BOOK. See the article **BOOK-KEEPING**.

CASHEW-NUT, in botany. See the article **ANACARDIUM**.

CASHIER, a person who is entrusted with the cash of some public company. See the articles **CASH** and **COMPANY**.

CASIA, in botany, the same with **OSYRIS**. See **OSYRIS**.

CASING of *Timber-work*, is plaistering a house all over on the outside with mortar, and then striking it while wet by a ruler with the corner of a trowel, or the like, to make it resemble the joints of free-stone. This is chiefly, or ought to be done upon heart-laths, because the mortar will decay those made of sap in a very little time; and though it be more work to lath it with heart-laths, yet it is necessary, because the mortar requires the laths closer together than loam. They commonly lay the mortar on two thicknesses, viz. the last before the first is dry.

CASK, a vessel of capacity for preserving liquors of divers kinds, and also sometimes dry goods, as sugar, almonds, &c.

A cask of sugar is a barrel of that commodity, containing from eight to eleven hundred weight. A cask of almonds is about three hundred weight.

A cask in slaves, that of which all the slaves are ready prepared, and want only to be joined and hooped. They are often shipped thus on board the vessels designed for the American islands, because they take less room, and can be easily made up there.

CASSAVI, or **CASSADA**, the same with the *jatropha* of Linnæus. See the article **JATROPHA**.

Of the root of this plant, which is oblong and thick, the Americans make a kind of bread, said to be a wholesome and nourishing food.

CASSIA, *Caryophyllata*, the bark of a tree of the clove kind, brought from the island of Cuba, Jamaica, and other parts of the West-Indies; rolled up in quills, like cinnamon, but somewhat thinner, rougher on the outside, and of a darker rusty brown colour.

This bark is a warm aromatic, nearly of the same kind of smell and taste with the clove spice, but weaker, and with a little admixture, as it were, of the cinnamon flavour. It agrees nearly with cloves also in regard to the solubility and volatility of its active principles. Tinctures of it in rectified spirit, smell and taste strongly of the bark: the watery infusions are considerably impregnated with its smell, but have very little of its taste. On inspissating the spirituous tincture, the spirit which distils has little or nothing of its flavour: the remaining extract smells lightly of the bark, and proves in taste very hot and pungent, though much less so than the spirituous extract of cloves. In distillation with water, it yields a very small portion of essential

oil, nearly similar in flavour to oil of cloves, but more pungent than the genuine oil of that spice: the remaining decoction is ungratefully austere and bitterish.

A bark of the same kind is sometimes brought from the East-Indies under the name of culildawan, or culilawan, a Malaccan compound word, of which the Latin *cortex caryphylloides*, or clove bark, is said to be a translation. That distinguished in Europe by the name of calilawan, is thicker than the other, and in colour approaches somewhat more to cinnamon, but scarcely differs in smell or taste.

The same with this appears likewise to be the carabacium of Baglivi; which he describes as being in taste like cloves, but very temperate and grateful, and in colour having a great resemblance to cinnamon; and which, he says, he made use of with great benefit in decoction, for correcting the acrimony and scorbutic dissolution of the lymph, and for strengthening the stomach and promoting digestion.

CASSIA Fistularis, a hard woody cylindrical pod of a tree resembling the walnut, which grows spontaneously in Egypt and the warmer parts of the East-Indies, and has been thence introduced into the West.

The pods or canes are about an inch in diameter, and a foot or more in length; externally, of a dark brown colour, somewhat wrinkled, with a large seam running the whole length upon one side, and another less visible on the opposite one; internally, of a pale yellowish colour, divided by thin transverse woody plates into a number of little cells, containing each a flattish oval seed, with a soft black pulp.

The pulp of cassia, whether moist or dry, dissolves both in water and in rectified spirit. It is usually extracted by boiling the bruised pods in water, and evaporating the strained solution to a due consistence: the exhaling vapour carries off nothing considerable of the cassia. As it is very apt to grow sour in keeping, only small quantities should be prepared at a time.

Cassia, in doses of a few drams, is a gentle laxative; of good use in costive habits, in inflammatory cases where purgatives of the more acrid or irritating kind can have no place; and, as Geoffrey observes, in the painful tension of the belly which sometimes follows the imprudent use of antimonials. It is rarely given in such doses as to have the full effect of a cathartic; the quantity necessary for this purpose, an ounce and a half, or two ounces, being apt to nauseate the stomach, and produce flatulencies and gripes, especially if the cassia is not of a very good kind: mild aromatics, and dilution with warm liquors, are the best correctives.

CASSIA Lignea, the bark of a tree of the cinnamon-kind, brought from the East-Indies; exactly

resembling cinnamon in appearance, but distinguishable by its breaking short or smooth, while cinnamon breaks fibrous or shivery, like wood.

This bark resembles cinnamon in aromatic flavour as well as in external appearance; but differs in being weaker, or containing less active matter, and in its abounding with a viscous mucilaginous substance. Chewed, it dissolves as it were in the mouth into a kind of slime: powdered and boiled in water, it renders a considerable quantity of the fluid thick and glutinous, so as to concrete on cooling into the consistence of a jelly.

Cassia lignea was employed by the ancients as a succedaneum to cinnamon, of which it was reckoned equivalent to half its own quantity. At present it is not unfrequently mixed with that spice in the shops, but is scarcely ever made use of under its own name.

CASSINE, the cassia-berry-tree, in botany, a genus of plants, the flower of which is patent, divided into five suboval, obtuse segments larger than the cup; the fruit is a roundish berry with three cells, containing solitary suboval seeds. This plant is used in South America in the same manner as tea.

CASSIOPEA, in astronomy, a constellation of the northern hemisphere, situated next to Cepheus, and opposite to the great bear on the other side of the pole.

In the year 1572, there appeared a comet in this constellation, which continued visible about eighteen months and then disappeared again. This comet appeared to the naked eye about the magnitude and brilliancy of Jupiter; which made some imagine it only to be a new star that made its appearance and then vanished again; but such must be very superficial, or little practiced in astronomy or astronomical observations. However, it greatly alarmed the astronomers of that age, many of whom wrote dissertations upon it, to prove that it was the same comet that appeared to the magi, or wise men of the East, at the birth of Christ.

In fabulous history, we are told, that Cassiopea was the wife of Cepheus and the mother of Andromeda, whom Perseus married, and for his sake was translated into heaven, as some write. Others say, that her beauty being singular, she became so exceeding proud, that she preferred herself before the Neriads, who were the nymphs of the sea; for which cause they placed her in the heavens with her head downwards; so that in their apparent revolution she might seem to be carried or hurled headlong, for an example to all such who should, in the pride of their hearts, advance themselves above their superiors.

We fancy were all the ladies in these days that are found guilty of this crime, placed in heaven in the same position, our astronomers royal would never be at a loss for objects to put all the un-

formed

C A S

formed stars into constellations. The stars of this constellation, according to Ptolemy, are thirteen, in Tycho twenty-eight, and in the British Catalogue fifty-five, as follow, with their places, &c.

CASSOCK, or CASSULA, a kind of robe or gown, wore over the rest of the habit, particularly by the clergy.

The word cassock comes from the French *casaque*, an horseman's coat; some derive that again from the garment of the Cossacs.

CASSOWARY, in ornithology, makes a distinct genus of birds, of the order of the gallinæ; the characters of which are these: its feet have each three toes, all placed forward; and its head is ornamented with a kind of bony comb and naked wattles.

There is only one species of this genus, which is a robust, large, and thick bird, measuring four feet and an half when it stretches out its neck.

CASSMUNAR, in the materia medica, is the root of an East-India plant, of which we have no certain account; brought over in irregular slices of various forms, some cut transversely and others longitudinally: the corticle part is marked with circles, and of a dusky brownish colour: the internal part is paler, and unequally yellow.

This root was introduced some time ago by Marloe, as a medicine of uncommon efficacy in hysteria, epileptic, paralytic, and other nervous disorders. At present it is sometimes employed as a stomachic; but its use is not yet become so general as it seems to deserve. It is an elegant mild aromatic, moderately warm, lightly bitterish; in smell somewhat resembling ginger.

CASTANEA, the chestnut-tree, in botany, a genus of trees, whose characters are: the flower is of the amentaceous kind, being composed of a number of stamina, arising from a five leaved cup, and fixed to a slender capillament, or axis. These are the male flowers, but the fruit grows on other parts of the tree; these are roundish, echinated, and open into four parts, and contain chestnuts with their kernels.

M. Tournefort has enumerated four, and Mr. Miller five species of castanea.

These trees are propagated by planting them in February, in beds of fresh, undunged earth: the best nuts for sowing are such as are brought from Portugal and Spain, and are commonly sold in winter for eating, provided they are not kiln-dried, which

which is generally the case of those brought from abroad; which is done to prevent their sprouting or rooting in their passage; therefore, if they cannot be procured fresh from the tree, it will be much better to use those of the growth of England, which are full as good to sow, for timber or beauty, as any of the foreign nuts, though their fruit are much smaller; these should be preserved until the season for sowing, in sand, where mice, or other vermin, cannot come to them, otherwise they will soon destroy them. Before you set them, it will be proper to put them into water, to try their goodness, which is known by their ponderosity; those of them that swim upon the surface of the water should be rejected, as good for nothing; but such as sink to the bottom you may be sure are good.

In April these nuts will appear above ground; you must, therefore, observe to keep them clear from weeds, especially while young: in these beds they may remain for two years, when you should remove them into a nursery, at a wider distance. The best season for transplanting these trees is either in October, or the latter end of February; but October is the best season: the distance they should have in the nursery, is three feet, row from row, and one foot in the rows.

After having remained three or four years in the nursery, they will be fit for transplanting, either in rows, for avenues to a house, or in quarters, for wilderness plantations; but if you intend them for timber, it is much the better method to sow them in furrows, as is practised for oaks, &c. and let them remain unremoved; for these trees are apt to have a downright tap root, which being hurt by transplanting, is often a check to their upright growth, and causes them to shoot out into lateral branches, as is the case with the oak, walnut, &c.

CASTANET, a musical instrument of the pulsative kind, wherewith the Moors, Spaniards, and Bohemians, accompany their dances, sarabands, and guitars, serving only to direct the time.

It consists of two little round pieces of wood, dried and hollowed, in the manner of a spoon; the concavities whereof are placed one on another, fastened to the thumb, and beat, from time to time, with the middle finger, to direct their motions and cadences: they may beat eight or nine times in the space of a measure, or second of a minute.

CASTELLAN, the name of a dignity or charge in Poland: the castellans are senators of the kingdom, but senators only of the lower class, who, in diets, sit on low seats, behind the palatines, or great senators. They are a kind of lieutenants of provinces, and command a part of the palatinate under the palatine.

CASTILLAN, or **CASTILLANE**, a gold coin, current in Spain, and worth fourteen rials and sixteen deniers.

CASTILLAN is also a weight used in Spain for weighing gold. It is the hundredth part of a pound Spanish weight.

What they commonly call a weight of gold in Spain, is always understood of the castilian.

CASTING, in foundry, the running of a metal into a mould, prepared for that purpose.

CASTING of Lead, is the using a frame, or mould, covered with sand, to cast the lead into sheets.

CASTING of Metals, of Letters, Bells, Figures, &c. See the article **FOUNDRY**.

CASTING in Sand and Earth, is the running of metals between two frames, or moulds, filled with sand or earth, wherein the figure that the metal is to take has been impressed *en creux*, by means of the pattern.

CASTING, among sculptors, implies the taking casts and impressions of figures, busts, medals, leaves, &c.

The method of taking off casts of figures and busts, as at present practised, is most generally by the use of plaster of Paris; or, in other words, alabaster calcined by a gentle heat. The advantage of using this substance preferably to others, consists in this, that notwithstanding a slight calcination reduces it to a pulverine state, it becomes again a tenacious and cohering body, by being moistened with water, and afterwards suffered to dry; by which means either a concave or a convex figure may be given by a proper mold or model to it when wet, and retained by the hardness it acquires when dry: and from these qualities, it is fitted to the double use of making both casts and molds for forming those casts. The plaster is to be had ready prepared for those who make it their business to sell it; and the only care is to see that it is genuine.

CASTLE-WARD, or **CASTLE-GUARD**, a tax laid on such as dwell within a certain distance of a castle, towards the maintenance of those that watch and ward the castle: the word is sometimes used for the circuit itself inhabited by such as are subject to this service.

CASTLE-WORK, service or labour done by inferior tenants for the building and upholding of castles of defence, towards which some gave their personal assistance, and others paid their contributions. This was one of the three necessary charges to which all lands among our Saxon ancestors were expressly subject.

CASTOR. See **BEAVER** and **CASTOREUM**.

CASTOR, in astronomy, the name of one of the twins in the constellation Gemini; as likewise of the star marked alpha by Bayer in the same constellation, or the sixty-sixth, according to the British order. See the catalogue of Gemini for Castor's place.

CASTOR and **POLLUX**, two meteors which sometimes, in a storm at sea, appear sticking to some part of

of the ship, in the shape of two fire-balls: when only one is seen, it is more properly called Helena. The two together are adjudged to portend a cessation of the storm; but one alone portends ill, and that the severest part of the tempest is yet to come: both these balls are by some called Tyndarides.

CASTOREUM, CASTOR, the inguinal glands of the castor or beaver, a four footed amphibious animal, frequent in several parts of Europe, and in North-America. These glands are of different shapes and sizes, covered with a thick skin, including an unctuous liquid matter, which in keeping grows dry and hard: on cutting the dry cods, as they are called, they are found full of a brittle friable substance, of a brownish red colour, interspersed with fine membranes and fibres exquisitely interwoven. The best castor comes from Russia, in large round, hard cods; an inferior sort, smaller and moister, from Dantzick; the worst of all from New England, in longish thin cods.

Russia castor has a strong not agreeable smell, and a biting bitterish nauseous taste: the other sorts are weaker than that of Russia, yet more ungrateful. It is generally looked upon as one of the capital nervine, antispasmodic, and antihysterical medicines: its virtues have undoubtedly been much exaggerated; but though they are not near so great as they have by most writers been represented, they appear nevertheless to be considerable. The common dose is from two or three grains to a scruple; though it has been sometimes taken by drams, and these doses very often repeated.

Castor is commonly joined in prescription with the deobstruent fetid gums, volatile alkaline salts, the volatile oily spirits, and other materials of similar intention. The volatile oily spirits are well adapted also as menstrua for dissolving the active matter of the castor, at the same time that they prove in many cases excellent additions to its virtue, as particularly in some hysterical disorders, and the several symptoms which accompany them: in this view, an ounce of Russia castor, and half as much asafetida, are digested about six days, in a close vessel, with a pint of the volatile spirit.

CASTRATION, in surgery, the operation of gelding. See **SARCOCELE**.

CASU CONSIMILI, in law, a writ of entry granted where a tenant, by coftsely or for life, aliens either in fee, in tail, or for the term of another's life. It is brought by him in reversion against the person to whom such tenant does so alien to the prejudice of the reversioner, in the tenant's like-time.

CASU PROVISO, in law, a writ of entry founded on the statute of Gloucester, where a tenant in dower aliens the lands she so holds in fee, or for life; and lies for the party in reversion against the alienee.

CAT, Felis, a well known quadruped, of the

order of the feræ, or beasts of prey. See the article **FELIS**.

CAT, in the marine, a sort of taicle, or complication of pulleys, to draw the anchor perpendicularly up to the cat-head.

CAT-MINT, in botany, the English name of the cataria of botanists.

CAT of the Mountain, Catus Pardus, an animal of the cat-kind, about the size of a mastiff, variegated with longitudinal black streaks on the upper-part of the body, and black spots on the under-part.

CATABIBAZON, in astronomy, the moon's descending node; also called the dragon's-tail.

CATACAUSTICS, or **CAUSTICS**, in the higher geometry, are curves formed by reflected rays. Mr. Mac Laurin defines them thus: rays of light being supposed to issue from a given point, and to be reflected by a given curve, so as to make the angle of reflection equal to the angle of incidence, a curve that touches all the reflected rays, is called the caustic by reflection. Thus, let *S* (Plate XXX. fig. 4.) be the given point from which the rays issue, which is therefore called the focus of the incident rays; *SL* any incident ray, *PLP* the tangent at *L*, *LC* the ray of curvature at *L*, *Lm* the reflected ray constituting the angle *CLM* equal to *CLS*; then, if the reflected rays always touch the curve *hmc*, it is the caustic by reflection. Let *SP*, perpendicular to the tangent *LP*, meet it always in *P*, a point of the curve *DP*; let *HME* be the curve by the evolution of *DP* is described; and let *PM* touch *HME* in *M*; join *SM*, and produce it to *m*; so that *Sm* be equal to *QSM*: then *m* shall be a point in the caustic of the curve *BL*, when *S* is the radiating point. For, because *MP* is perpendicular to the curve *DP*, the angle *MPS* is equal to the complement of *SLP*, or to *LSP*; and *SL* is bisected by *MP* in *K*; therefore *Sm* is to *SM* as *SL* is to *SK*. *Lm* is parallel to *KM*, the tangent of *HME*: but the figure *hmc* is similar to *HME*, and similarly situated; therefore *Lm* is the tangent of *hmc*. Because *Lm* is parallel to *PM*, the angle *mLC* is equal to *MPS*, or *LSP*, or *CLS*; therefore, when *SL* is the incident ray, *Lm* is the reflected ray, and *m* is a point to the caustic.

Again, let *Lf* be taken on the reflected ray equal to *LS*; and *CR* being perpendicular from the center of curvature on this ray in *R*, bisect *LR* in *q*; and *qf*, *qR*, and *qm* shall be in continued proportion. For *fQ*, *fL* and *2PM* are in continued proportion. Let *CI* be perpendicular to *SL* in *I*, and *IL* be bisected in *Q*; when *S* is on the concave side of the curve, and *LS* is greater than *LQ*, *PM* is equal to the sum of *PK* (or *SK*) and *KM*, and *2PM* is equal to the sum of *fL* and *Lm*; therefore *fQ* is to *qL* or *qR* as *fL* is to *LM*, or as *qR* is to *qm*. When *S* is betwixt *Q* and *L*, *2PM*

2 P M is equal to the difference of $L m$ and $L f$, and $f q$ is to $q L$, as $f L$ is to $L m$, or as $q L$ or $q R$ is to $q m$. In like manner it appears, that when S is on the convex side of the curve $f q$, $q R$ or $q L$, and $q m$ are in continued proportion. When the incident ray is perpendicular to the curve (as in *fig. 5*) the reflected ray coincides with the incident ray; f with S , R and C , and $q m$, $q C$, $q S$ are in continued proportion. In general the rectangle $f q m$ is equal to the square of $q R$ or $q L$; and when the incident rays are parallel, the point must coincide with q and $L m$, and be equal to one half of $L R$. When $L S$ is equal to one half of $L I$, and S is on the concave side of the curve, f coincides with q , and the reflected ray $L m$ becomes an asymptote of the caustic.

Again, let $B L$ be a circle, (*fig. 6*.) C the center, $C B$ the radius that passes through S , the radiating point; bisect $B C$ in q . Let $q S$, $q C$, and $q H$, be in continued proportion: when $C S$ is less than one half of $C B$, the curve $D P$ has no point of contrary flexure, and the caustic has no asymptote. When $C S$ is equal to one half of $C B$ the diameter, through S is the asymptote to the caustic. When $C S$ is greater than one half of $C B$, but less than $C B$, the caustic meets $C B$ produced beyond B , the part of the curve $D P$, adjoining to B , is convex towards S ; P is a point of contrary flexure, when $S L$ is one fourth part of the chord $L Z$ that passes through S , and the reflected ray is then an asymptote of the caustic.

Again, let $S A$ (*fig. 4*.) be a right line given in position, and $L m$ shall be to $S L$ as the fluxion of the angle $A S L$ to the fluxion of $2 A S P$ — $A S L$. Hence $L m$ is to $S L$ in an invariable ratio; because the angle $A S L$ is to $A S P$ in an invariable ratio, only, in the parabola; S being the focus the fluxion of $A S L$, is equal to the fluxion of $2 A S P$, and the reflected rays are parallel to each other, and to the axis of the figure. It may not be amiss to give an example of describing the caustic by reflection to a given curve.

Let the curve be the logarithmic spiral as represented by $A C D$, (*fig. 7*.) and suppose the rays of incidence to issue from the luminous point A its center, and let it be required to describe the catacaustic $A F K$ by reflection.

Let the line $C H$ be drawn perpendicular to the curve in the point C , and $A H$ perpendicular to the ray of incidence $A C$, then the point H will be in the evoluta of the curve, and consequently $A C$ will be equal to y the abscissa of the curve, which is

equal to a ; whence $C F = \frac{a y}{2 y - a}$ will be equal to y , and the triangle $A C F$ will be an isosceles triangle; and because the angle of incidence $A C V$ is equal to the angle of reflection $F C S$; therefore the angle $A F C$ is equal to $A C V$; and this angle $A C V$, being a constant quantity, by the nature of

the curve; therefore the angle $A F C$ will be a constant quantity, and the caustic by reflection $A F K$ will be a logarithmic spiral, differing from the given spiral only in position.

When the given curve is a geometrical one, the caustic will be so too, and the caustic will always be rectifiable. The caustic of a circle is a cycloid, formed by the revolution of a circle along a circle. The caustic of the vulgar semi-cycloid, when the rays are parallel to the axis thereof, is also a vulgar semi-cycloid, formed by the revolution of a circle on the same base.

CATACHRESIS, in rhetoric, a trope which borrows the name of one thing to express another. Thus Milton, describing Raphael's descent from the empyreal Heaven to Paradise, says,

“Down thither prone in flight

“He speeds, and through the vast ethereal sky

“Sails between worlds and worlds.”

CATACOMB, a grotto or subterraneous place for the burial of the dead.

The term is particularly used in Italy for a vast assemblage of subterraneous sepulchres, three leagues from Rome, in the Via Appia, supposed to be the sepulchres of the ancients. Others imagine these catacombs to be the cells wherein the primitive Christians hid themselves. Each catacomb is three feet broad, and eight or ten high, running in form of an alley or gallery, and communicating with one another.

Some authors suppose them to have been the puticuli mentioned by Festus Pompeius, into which the Romans threw the bodies of their slaves, to whom they denied the honours of burying; and Mr. Monro, in the Philosophical Transactions, gives it as his opinion, that the catacombs were the burial-places of the first Romans, before the practice of burning the dead was introduced; and that they were dug in consequence of these opinions, that shades hate the light, and love to hover about the places where their bodies were laid.

CATACOSTICS, an appellation given to the doctrine of reflected sounds. See ECHO.

CATADIOPTICAL TELESCOPE, that otherwise called a reflecting one. See the article TELESCOPE.

CATADROME, an engine like a crane, used by builders in raising weights.

CATADUPA, a water-fall, or cataracl. See the article CATARACT.

Hence the inhabitants about the cataracls of the Nile were called catadupi by the ancients.

CATAPALCO, in architecture, a decoration of sculpture, painting, &c. raised on a timber-scaffold, to shew a coffin or tomb in a funeral solemnity.

CATALEPSY, *Catalepsis*, in physic, a kind of apoplexy; or a disease wherein the limbs are easily flexible,

flexible, and continue in whatever position they are placed.

The word is derived from *καταλαμβάνω*, to seize, or interrupt.

The natural causes which generally bring on the paroxysms of a catalepsia, are a peccancy of the thick and viscid humours, and intense cold; and the accidental are violent commotions of the mind, grief, terror, joy, fear, and sadness.

As to the prognostics of a catalepsia, if it is produced by the passions of the mind, or profound meditations, it is seldom attended with dangerous consequences: but, on the contrary, when it proceeds from a thick, viscid, and impure blood, or from a suppression of accustomed evacuations of blood, it is highly dangerous; for it either terminates in melancholy, or is changed into an epilepsy; or, lastly, terminates in a violent apoplexy, and kills the patient. Nor is the congelation brought on by extreme cold of less danger; since, if seasonable relief is not afforded, sudden death ensues.

In the cure of this terrible disorder, two curative intentions are principally to be regarded. The first is to relax the spasmodic stricture of the small nervous fibres in the brain. The second is cautiously to remove the material or secondary causes which contribute to the production of this constriction. The former is principally to be answered during the paroxysm, but the latter when the person is out of it.

CATALLIS CAPTIS NOMINE DISTRICTIO, in law, a writ which lies where a house is within a borough, for rent issuing out of the same: and this writ warrants the taking of doors or windows by way of distress.

CATALLIS REDENDIS, a writ that lies where goods being delivered to a person to keep until a certain day, are not on demand delivered on that day.

CATALOGUE, a list or enumeration of the names of several books, men, or other things, according to a certain order.

CATALOGUE of Stars, an enumeration of the constellations, with the stars belonging to each, put down in a list according to their place, or order of passing the meridian, with their number, both formed and unformed, as likewise their magnitude, variations, &c. or whatever may be of use to the practical astronomer, for his more readily applying any, or such of them as is most suitable, to adjust the motions of the planets, comets, &c.

Pliny informs us in his Natural History, that Hipparchus of Rhodes, observing the appearance of a new star, began to think there might be changes amongst the fixed stars; he therefore began to construct a catalogue of them, that in time to come, if any new stars should appear, or any of those already observed should vanish or diminish, such changes could not escape unnoticed to after-ages.

The most ancient catalogue is that of Ptolemy, which contains 1026 stars. These were chiefly copied from Hipparchus, only he corrected their places by his own observations, made in the beginning of the reign of Antoninus Pius, about the year 140.

According to the learned Hyde, the Arabians were the next after Ptolemy, who made a catalogue of the stars; he mentions several, and published the most considerable among them in Arabic, with a Latin translation: it was made by Ulug Beigh, grandson to Tamerlane, from his own observations made at Scamercand. The number of stars in this catalogue were 1022, and their places settled to the year 1437.

The third, who made a catalogue from his own observations, was Tycho Brahe, who determined the places of 777 stars for the year 1600: which Kepler, from other observations of Tycho's, afterwards increased to 1000, which he published with the Rudolphine tables.

At the same time, William, landgrave of Hesse, with the assistance of Rothmannus and Justus Byrgius, settled the places of 400 fixed stars by his own observations, which Hevelius prefers to those of Tycho. Ricciolus, in his *Astronomia Reformata*, determined the places of 101 stars for the year 1700, from his own observations. Dr. Halley, in the year 1677, at the island of St. Helena, observed 350 southern stars, not visible in our horizon. The same labour was repeated by F. Noel in 1710, who published a new catalogue of the same stars, settled for the year 1687. The next was J. Hevelius, who made a catalogue of 1888 fixed stars, whereof 950 had been observed by the ancients, 350 by Dr. Halley, and 603 by himself.

The largest and most complete is the British catalogue constructed by Mr. Flamsteed; it contains 2936 stars, their places being rectified to the year 1680; but in this Dictionary to the year 1770, and from more accurate observations.

Bayer, in his *Uranometria*, published a catalogue of 1160 stars, though not from his own observations, but chiefly compiled from those of Ptolemy and Tycho. What makes this catalogue valuable is, that each star in every constellation is marked with some letter; so that the biggest star in every constellation is denoted by the first letter of the Greek alphabet, and the next biggest by the second, &c.; but if the constellation contains a greater number of stars than there are letters, than those that remain are marked by the Roman alphabet: by this means every star is easily distinguished.

CATAMENIA, in medicine, the same with menses. See **MENSES**.

CATANANCHE, in botany, a genus of plants producing compound flowers. The proper flower is monopetalous, ligulated, linear, longer than the calyx, truncated and quinque-dentate. The ger-

men is situated below the flower, and becomes afterwards a solitary compressed seed, crowned with a little cup of four or five hairs.

CATAPACTYME, a festival kept by the Peruvians in the month of December, in honour of the sun the father, the sun the son, and the sun the brother.

CATAPAN, a name given by the Greek emperors to the governor of Puglia and Calabria in Italy. They succeeded the exarchs of Ravenna; and Du Cange is of opinion, a chronological table of these governors might be very serviceable for understanding the Byzantine historians.

CATAPASM, among ancient physicians, signifies any dry medicine reduced to powder, in order to be used by way of inspiration in the whole body, or any part of it. Some cataplasms are appropriated to ulcers, some to the skin: the former cicatrize, the later are deterfive. We learn from Pliny, that cataplasms of roses were used to restrain sweat, and to dry the body after bathing.

CATAPHONICS, the science which considers the properties of reflected sounds. See the article **ECHO**.

CATAPHORA, in medicine, the same as coma. See the article **COMA**.

CATAPHRACTA, in antiquity, a kind of coat of mail, which covered the soldier from head to foot.

Hence cataphracti were horsemen armed with the cataphracta, whose horses, as Sallust says, were covered with linen full of iron plates disposed like fishscales.

CATAPHRYGIANS, ancient heretics, who took their name from the country of Phrygia. They supposed the Holy Spirit had abandoned the church, and therefore that Montanus, as a prophet, and Priscilla and Maximilla, as true prophetesses, were to be consulted in every thing relating to religion. See the article **MONTANIST**.

CATAPLASM, in pharmacy, an external soft kind of medicine of the consistence of pretty thick panada, and prepared of ingredients of different virtues, according to the intention of the physician.

The word is formed from *κατα*, with, and *πασσων*, to anoint.

CATAPULTA, in antiquity, a military engine contrived for throwing of arrows, darts, and stones upon the enemy. Some of these engines were of such force, that they would throw stones of an hundred weight. Josephus takes notice of the surprising effects of these engines, and says, that the stones thrown out of them beat down the battlements, knocked off the angles of the towers, and would level a whole file of men, from one end to the other, were the phalanx never so deep.

CATARACT, in hydrography, a precipice in the channel of a river, caused by rocks, or other

obstacles, stopping the course of the stream, from whence the water falls with a great noise and impetuosity: such are the cataracts of the Nile, the Danube, Rhine, and the famous one of Niagara in America.

CATARACT, in medicine and surgery, a disorder of the humours in the eye, by which the pupilla that ought to appear transparent and black, looks opaque, grey, blue, brown, &c. by which vision is variously impeded, or totally destroyed.

The ordinary and most common cause of cataracts, is from an opacity in the crystalline lens: it appears that it may sometimes be caused by a membrane in the aqueous humours, which cause was the only one ascribed to cataracts till the present century.

Cataracts have been distinguished by surgeons and oculists into various species, as into recent and inveterate, incipient and confirmed, mature and immature, simple and complicated, immovable and shaking, milky and purulent, true and spurious, and into curable and incurable. There is scarce any disorder, the event of which is more uncertain than that of a cataract: medicines will generally have little or no effect when the disorder is confirmed, or inveterate, notwithstanding what some may boast of their wonderful arcana for this purpose: almost the sole relief is therefore had from the surgeon's hand and instruments. For the process of this operation, see the article **COUCHING of Cataracts**.

Though most people reject all methods of treating cataracts by medicines as useless and trifling, yet there are some cases in this disorder which ought to be recommended to the care of the physician, who by directing a proper regimen and course of physic, adapted to the patient's habit, age, and other circumstances, may by the assistance of nature remove cataracts beyond expectation.

CATARRH, in medicine, a distillation or deffluxion from the head upon the mouth and aspera arteria, and through them upon the lungs.

The cause of this disorder proceeds from the lymph, or mass of blood, most frequently in the winter time, as it commonly arises from a cold. If it is attended with a fever, as it almost always is, in some degree, it is called a catarrhus fever.

The catarrhus suffocatus is a violent and suffocating cough, excited either by an excessive catarrh, or cold; by the rupture of a vomica in the lungs; by a polypus driven from the heart in the pulmonary artery; or sometimes by a spasmodic constitution of the nerves, as it happens in some hysterical cases.

Catarrhus disorders, as well as all other feverish indispositions, are to be treated in a mild and gentle manner; and the patient is to be kept moderately warm, either in bed, or by means of a fire: he is to abstain from medicines which are too hot, drastic, and productive of commotions; as also from a hot regimen.

regimen. The diet is to be spare, and the drink tepid and wholesome: the most proper is excocticated barley, with shavings of hartshorn, raisins, and liquorice root.

When the effervescence is violent, a few grains of nitre may be advantageously mixed with the bezoardic powders; and emulsions must be plentifully drank: when during this disorder, the faces are indurated, and the patient costive, besides water-gruel, decoctions of manna, &c. are to be drank; and nothing is more proper than emollient clysters.

Some distinguish catarrhs into three kinds, calling it bronchus, when the humours of the head fall upon the jaws; coryza, when they fall upon the nostrils; and rheum, when they fall on the breast. See the articles BRONCHUS, CORYZA, and RHEUM.

CATASTASIS, *καταστασις*, in poetry, the third part of the ancient drama, being that wherein the intrigue, or action, set forth in the epitasis, is supported and carried on, and heightened, till it be ripe for the unravelling in the catastrophe. Scaliger defines it, the full growth of the fable, while things are at a stand in that confusion to which the poet has brought them.

CATASTROPHE, in dramatic poetry, the fourth and last part in the ancient drama, or that immediately succeeding the catastasis: or, according to others, the third only; the whole drama being divided into protasis, epitasis, and catastrophe; or, in the terms of Aristotle, prologue, epilogue, and exode.

The catastrophe clears up every thing, and is nothing else but the discovery or winding up of the plot. It has its peculiar place, for it ought entirely to be contained, not only in the last act, but in the very conclusion of it; and when the plot is finished, the play should be so also. The catastrophe ought to turn upon a single point, or start up on a sudden.

The great art in the catastrophe is, that the clearing up of all difficulties may appear wonderful, and yet easy, simple, and natural.

It is a very general, but very preposterous artifice of some writers, to shew the catastrophe in the very title of the play. Mr. Dryden thinks that a catastrophe resulting from a mere change in sentiments and resolutions of a person, without any other machinery, may be so managed as to be exceeding beautiful. It is a dispute among the critics, whether the catastrophe should always fall out favourably on the side of virtue, or not. The reasons on the negative side seem to be the strongest. Aristotle prefers a shocking catastrophe to a happy one. The catastrophe is either simple or complex; the first is that in which there is no change in the state of the principal persons, nor any discovery or unravelling, the plot being only a mere passage out of agitation into quiet repose. In the second, the principal persons undergo a change of fortune, in the manner already defined.

CATCH, or CATCHES, in mechanics, those parts which lay hold of others by hooking or catching hold of them.

CATCH-FLY, in botany, a perennial plant, producing gramineous leaves, which come out of the root without order, and lay near the ground: between these come up straight single geniculated stalks, about a foot and a half high; from each joint come out two leaves placed opposite, and like the lower ones; the stalk is terminated in a loose spike of red-purple flowers: these appear in May or June.

The double sort of catch-fly is very common in gardens: it is a plant which will bear the severest of our winters; and is easily propagated by parting the roots in autumn. For the generical characters of this plant, see the article Lychnis, of which it is a species.

CATCH-WORD, among printers, that placed at the bottom of each page, being always the first word of the following page.

CATECHISM is defined in the Liturgy of the church of England, an institution to be learned of every person before he brought to be confirmed by the bishop.

The catechisms of the primitive church usually began with the doctrine of repentance and remission of sins, the necessity of good works, and the nature and use of baptism; then followed the explanation of the several articles of the creed, to which some added the doctrine of the immortality of the soul, and an account of the canonical books of Scripture.

The time appointed for catechizing are Sundays and holidays. Every parson, vicar, or curate, are enjoined upon every Sunday and holiday, to teach and instruct the youth, and ignorant persons of his parish, in the catechism set forth in the book of Common-Prayer; and that under the penalty of a sharp reproof for the first omission, suspension for the second, and excommunication for the third.

CATECHIST, an officer in the primitive Christian church, whose business it was to instruct the catechumens in the first principles of religion, and thereby prepare them for the reception of baptism.

This office might be performed by an ecclesiastic of any order, and it was sometimes done by the bishop himself.

CATECHU, in the materia medica. See TERRA Japonica.

CATECHUMEN, a candidate for baptism, or one who prepares himself for the receiving thereof.

The catechumens, in church history, were the lowest order of Christians in the primitive church. They had some title to the common name of Christian, being a degree above pagans and heretics, though not consummated by baptism. They were admitted to the state of catechumens by the imposition of hands and the sign of the cross. The children

children of believing parents were admitted catechumens as soon as ever they were capable of instruction: but at what age those of heathen parents might be admitted is not so clear. As to the time of their continuance in this state, there were no general rules fixed about it; but the practice varied according to the difference of times and places, and the readiness and proficiency of the catechumens themselves.

CATEGOREMA, among logicians, denotes much the same with predicament or category. See the article **CATEGORY**.

CATEGORICAL, whatever partakes of the nature of a category. Thus, a categorical order requires the substance to go before the accident. And categorical answers are pertinent and precise replies to the facts or objections proposed. See the article **CATEGORY**.

CATEGORY, κατηγορία, in logic, a series or order of all the predicates or attributes continued under any genus.

The school philosophers distribute all the objects of our thoughts and ideas into certain genera or classes, not so much, say they, to learn what they do not know, as to communicate a distinct notion of what they do know; and these classes the Greeks called categories, and the Latins predicaments.

Aristotle made ten categories, viz. quantity, quality, relation, action, passion, time, place, situation, and habit, which are usually expressed by the following technical distich:

*Arbor, sex, servus, ardor, refrigerat, ustos
Ruri cras stabo, nec tunicatus ero.*

But as the series of categories is entirely arbitrary, some philosophers think all nature may be better considered under these seven things; spirit, matter, quantity, substance, figure, motion, and rest: and others make but two categories, substance and accident.

CATENARIA, the name of a curve line, formed by a rope hanging freely from two points of suspension, whether the points be horizontal or not. The nature of this curve was sought after in Galileo's time; but little was done concerning it till the year 1696, when Mr. Bernoulli proposed it as a problem to the mathematicians of Europe. This catenary is a curve of the mechanical kind, and cannot be expressed by a finite algebraic equation.

If you suppose a line heavy and flexible, firmly fixed to the points AB (Plate XXX. fig. 8.) the extremes thereof, then its own weight will bend it into the curve ACB, called the catenary, whose fundamental property will be this, viz. $bc : Bd :: a : CB$, when DB, dc , are parallel to the horizon CD, perpendicular to AB, and Bb parallel to CD, and the points D and d , infinitely near to one another, and a be any given quantity. The demonstration of this property, as also of

many others, may be seen in what was published by Dr. Gregory in the year 1696: see also its construction and nature by Mr. J. Bernoulli, in the Acta Eruditorum, 1691, page 277.

Mr. Cotes, in his *Hærmonia Mensurarum*, gives the following concise, and yet plain, account of the nature of the catenarian curve. Let BAC (Plate XXX. fig. 9.) be a very slender chain, or rather mathematical line, flexible throughout by any small force, which can neither be extended or contracted. This suspend by its ends B, C, by the force of its own weight, equally diffused throughout all its equal particles, is stretched into the curve BPAC, it is required to find any points of this curve.

If a plane be supposed to pass through both its ends, B, and C, perpendicular to the horizon, it is evident that all the points of the proposed curve are situated in this plane, and so that each will descend as low as it can. Through its lowest point A draw AQ perpendicular to the horizon, and let PoQ drawn from any point P be perpendicular to it, and through p , being the nearest point to P possible, let $p\phi$ be drawn parallel to AQ; call $AQ = x$, $PQ = y$, and the arch $AP = z$; then will the very small lines $p\phi$, ϕP , and pP , be to one another, as $\dot{x}$, $\dot{y}$, $\dot{z}$. Then because the arch AP is sustained in equilibrio, by the force of its weight, whose direction is parallel to the line ϕp , by the force of the contiguous arch AC, drawing according to the direction of the tangent at A, parallel to the little line $p\phi$, and by the force of the contiguous arch PB, drawing in the direction of the line pP ; it is evident from mechanics, that these forces are to one another as ϕp , ϕP , and pP , or as $\dot{x}$, $\dot{y}$, $\dot{z}$. Therefore if the weight of the arch AP be expressed by its length z , and the given force drawing the arch AC, be compounded by a given length a , it will be $\dot{x} : \dot{y} :: \dot{z} : a$; and so $\dot{x} : \sqrt{\dot{x}\dot{x} + \dot{y}\dot{y}} :: \dot{z} : a$;

$\sqrt{aa + zz}$. Therefore $\dot{x} = \frac{az}{\sqrt{aa + zz}}$; and so

$a + x = \sqrt{aa + zz}$; wherefore $z = \sqrt{a + x^2} - \sqrt{aa + zz}$. Wherefore, if the right-line QA be continued downwards to D; so that DA be a , and the tangent AE be taken = to the arch AP and DE be joined, this will be equal to DQ. Wherefore if AE, the length of any arch AP, be given; as also AQ, the height of the said arch; there will be given AD = a , by joining QE and bisecting the same at right-angles; for the perpendicular will pass through the point D in the line QA continued, and AD being given, we from thence can find the line AE, the length of any arch AP, whose altitude AQ is given, by describing a circle from the center D, with the radius QA, which cuts AE in E; and these are the mutual relations of the parameter AD, the arch AP, and its altitude AQ. The next is to determine its breadth, and

and from what has been already advanced, we find

$$j = \frac{ax}{z} = \frac{ax}{x_2 \sqrt{2a + x}}, \text{ and the fluent of this last}$$

expression will be a hyperbolic space, which space may be measured by the logarithms: so that PQ will be the logarithm of the ratio between DE + EA and DA, or of AP + AQ to AP - AQ, which ratio is equal to the former, when the length of the line AD is equal to $e, 434294481903$. So that AD being given or found as above, if any point Q be taken in the axis AQ, so many correspondent points P of the curve will be had.

CATERPILLAR, *Eruca*, in zoology, the name of the butterfly-class of insects, in their reptile or worm-state.

It is well known that all winged insects pass through a reptile state, before they arrive at perfection: this great change from a worm to a fly, or butterfly, was formerly esteemed a real metamorphosis of one animal to another; but later discoveries have put it beyond all doubt, that the embryo butter-fly, with all the lineaments of its parent, is contained within the external cases, or coverings, of the caterpillar. When the included animal has acquired a sufficient degree of strength, these coverings are thrown off, and it appears in its genuine or most perfect form of a fly, or butter-fly. See FLY and BUTTER-FLY.

It is necessary, however, before the animal can get rid of these coverings, that it pass through a state of rest, called by naturalists the nymph or chrysalis-state. See the article NYMPH.

Whoever desires to have a more full account of these animals in their reptile and chrysalis-state, may consult the second volume of Reaumur's History of insects.

CATERPILLAR-EATERS, small worms bred from the eggs of certain flies, lodged in bodies of larger caterpillars.

CATERPILLAR-SHELL, the English name of the verrucose turbo, with a broad and depressed mouth. See TURBO.

CATERPILLAR-PLANT, in botany. See the article SCORPIURUS.

CATESBÆA, in botany, a shrub which grows naturally in the Bahama islands. It rises with a branching stem to the height of ten or twelve feet, which is covered with a pale russet bark. The branches come out alternately from the bottom to the top, and are furnished with small leaves like those of the box-tree, coming out in clusters round the branches at certain distances. The flowers, which are of a dull yellow colour, come out single from the side of the branches, hanging downward. Each of these are about six inches long, monopetalous, and funnel-shaped, very narrow at their base, but widening upward towards the top, where it is divided into four parts, which spread open, and is

reflexed backward. The germen is roundish, and when the flower is decayed, becomes an oval fleshy berry, with one cell, containing several angulated seeds. This plant is raised here from seeds; but being tender, it requires a hot-house in this climate to preserve it.

CATHÆRETICS, in pharmacy, the same with scarphagous medicines, or those of a caustic nature, serving to eat off proud flesh.

CATHARINE, or *Knights of St. CATHARINE*, a military order, instituted for the security of travellers who come to visit the tomb of this saint. The knights received, as a badge of their dignity, a broken wheel with a sword stained with blood. They took vows to guard the body of this saint, to secure the roads for pilgrims, to defend the rights of the church, to obey their superiors in all things, and follow the rule of St. Basil.

CATHARISTÆ, in church-history, a branch of the Manichees, so called from certain purifications which they were obliged to practise: they are also said to have held it unlawful to eat flesh.

CAT-HARPINGS, in naval affairs, ropes which draw in the shrouds parallel to the yards, that the yards may be more easily braced sharp for a side-wind. See the articles BRACE and CLOSE-HAULED.

CATHARTICS, in medicine, remedies which promote evacuation by stool. They are the same with what are commonly called purgatives.

Cathartics may be divided into two classes; 1. The ecoprotic or milder. 2. The drastic, or rougher. See ECCOPROTIC and DRASTIC.

They are likewise divided according as they are supposed to purge bile, pituita, melancholy, and ferocities, into cholagogues, phlegmagogues, melanagogues, and hydragogues. See CHOLAGOGUES, &c.

Cathartics operate by vellicating and irritating the fibres and membranes of the stomach and intestines. As the peristaltic motion of the guts is such as propels continually their contents, from the pylorus down to the rectum, every irritation either quickens that motion, in its natural order, or occasions some little inversion of it; in both, what but slightly adheres to the coats, or inner membranes, will be loosened and shook off, and carried forwards with the contents; and, being also more agitated, will be rendered more fluid: hence it appears how a cathartic hastens and increases the discharge by stools. But the same manner of operation carries its effects much farther in proportion to the force of the stimulus; for where it is great, the appendices of the bowels, and even all the viscera in the abdomen, will by a consent of parts, that is, a communication of nerves, be pulled or twitched, so as to affect their respective juices, in the same manner as the intestines themselves affect their contents. The consequences, therefore, must be, that a great part will be drained back into the intestines, and make a part of what they

they discharge. Another way of promoting the discharges by stool, and from fusion, is to mix such particles with them as prevent their running into viscid cohesions, and by degrees divide and break them when in contact; whence they are rendered fitter to run off by the most convenient outlets.

CAT-HEAD, in naval architecture, a fort of square beam of oak, projecting like a crane over the ship's bows, so as to keep the anchor clear of the ship when it is drawing up by a tackle, the block of which is called the cat-block: the rope which passes through the several sheaves of the block is called the cat-fall.

CATHEDRA, among ecclesiastical writers, denotes a bishop's see, or throne.

CATHEDRAL, a church wherein is a bishop's see or seat.

A cathedral was originally different from what it is now, the Christians, till the time of Constantine, having no liberty to build any temple. By their churches they only meant their assemblies; and by their cathedrals, nothing more than consistories.

CATHETER, in surgery, a fistulous instrument, usually made of silver, to be introduced into the bladder, in order to search for the stone, or discharge the urine when suppressed.

The catheter may be introduced with much more ease in women than in men, as the urethra in the first is much shorter, wider, and in a straighter course.

In both sexes, however, this instrument cannot be easily passed, but by one that is previously acquainted with the anatomical structure of the parts.

To prevent repeating the operation of passing the catheter when the retention of urine will follow in a short time, modern surgeons have, instead of the common or rigid catheter, provided a flexible catheter, made of flattened silver, convoluted in a particular manner to give a continual passage to the urine.

CATHETUS, in geometry, a line falling perpendicularly on another line or surface: thus the catheti of a right-angled triangle are the two sides that include the right-angle, or more properly that side or leg which is supposed to be perpendicular to the horizon, or that which is called the perpendicular, which is always determined by its position.

CATHETUS, in architecture, a perpendicular, or plumb line, falling from the extremity of the under side of the cimatum of the Ionick capital, thro' the center of the volute: or, in other words, that which is supposed to pass directly through the middle of a cylindrical or round body, as a baluster, or column, &c.

CATHETUS of Incidence, in catoptrics, a right line drawn from a point of the object perpendicular to the reflecting line.

CATHETUS of Reflection, or of the Eye, a right line drawn from the eye, perpendicular to the reflecting line.

CATHOLIC, in a general sense, denotes any thing that is universal or general.

CATHOLIC CHURCH. The rise of heresies induced the primitive Christian church to assume to itself the appellation of Catholic, being a characteristic to distinguish it from all sects, who, though they had party-names, sometimes sheltered themselves under the name of Christians.

The Romish church distinguishes itself now by the name of Catholic, in opposition to all those who have separated from her communion, and whom she considers as only heretics and schismatics, and herself only as the true and Christian church. In the strict sense of the word, there is no Catholic church in being; that is, no universal Christian community.

CATHOLIC KING, a title which hath been hereditary to the kings of Spain ever since Alphonsus.

CATHOLICON, in pharmacy, a kind of soft purgative electuary, so called, as being supposed an universal purger of all humours.

CATKIN, **KATKIN**, the same with an amantaceous flower. See **AMENTACEOUS**.

CATLIN, among surgeons, a knife for cutting off corrupted parts of the body.

CATOCHE, or **CATOCHEUS**, in medicine, a disease by which the patient is rendered, in an instant, as immovable as a statue, without either sense or motion, and continues in the same posture he was in at the moment he was seized. The proximate cause of this disease is the immobility of the common sensory, from the time of the first attack, and therefore is an absolute rest of the blood in the brain, of the glands of the brain, and of all its emissories. This disease is generally preceded by obstinate intermitting fevers; by a dry, lean, melancholy temperament of body; by a retention of the menses and hæmorrhoids; by sudden frights; by a profound, constant, and fixed meditation on one subject. It is often cured by exciting a copious hæmorrhage from the nose; but the particular method of cure is various, according to the different causes: the patient should be excited with things that greatly strike the senses, such as light, noise, stimulating things, volatile salts, pain, friction, continual agitations, by promoting the menstrual flux, by sternutatories, and emetics, by blisters, by illuses, by setons, by a moistening diet.

It seldom changes to any other disease, and sometimes it has been succeeded by an epilepsy, convulsions, madness, or an atrophy, which have ended in death.

CATOPTRICS, is that part of optics that treats of reflex vision, and explains the laws and properties of reflection, chiefly founded upon this truth, that the angle of reflection is always equal to the angle of incidence; and from thence deducing the magnitudes, shapes, and situation of the

appear-

appearances of objects seen by the reflection of polished surfaces, and particularly plane, spherical, conical, and cylindrical ones.

CATOPTRIC CISTULA, a machine, or apparatus, whereby little bodies are represented large, and near ones extremely wide, and diffused through a vast space, with other agreeable phenomena, by means of mirrors, disposed by the laws of catoptrics, in the concavity of a kind of a chest.

Of these there are various kinds, accommodated to the various intentions of the artificer: some multiply the object, some deform them, some magnify, &c. The structure of one or two will sufficiently shew how an infinite variety may be made.

To make a catoptric cistula to represent several different scenes of objects, when looking at different foramina or poles.

Provide a polygonous cistula, or chest of the figure of the multilateral prism ABCDEF, Plate XXX. fig. 10. and divide its cavity by diagonal planes EB, FC, DA, intersecting each other in the center into as many triangular locules or cells as the chest has sides. Line the diagonal planes with plane mirrors; in the lateral planes make round holes, thro' which the eye may peep into the locules of the chest. The holes are to be covered with plane glasses ground within-side, but not polished, to prevent the objects in the locules from appearing too distinctly.

In each locule are to be placed the different objects, whose images are to be exhibited; then cover up the top of the chest with a thin transparent membrane, or parchment, to admit the light properly, and the machine is compleat: for, from the laws of reflection, it follows, that the images of objects placed within the angles of mirrors are multiplied, and appear some more remote than others; whence the objects in one locule will appear to take up more room than is contained in the whole chest: therefore by looking through one hole only, the objects in one locule will be seen, but those multiplied and diffused through a space much larger than the chest: thus every new hole will afford a new scene. According to the different angles the mirrors make with each other, the representations will be different; if they be at an angle greater than a right one, the images will be monstrous. The parchment that covers the machine may be made pellucid by washing it several times in a very clear lye, then in fair water, and bracing it tight and exposing it to the air to dry. If it be desired to throw any colour on the objects, it may be done by colouring the parchment. Zahnus recommends verdigrease ground in vinegar for green; decoction of brasil wood for red, &c. He adds, it ought to be varnished to make it more pellucid.

To make a catoptric cistula to represent the objects within it prodigiously multiplied, and diffused through a vast space.

Make a polygonous cistula, or chest as before, but without dividing the inner cavity into any apartments or locules, (Plate XXX. fig. 11.) line the lateral planes CBHI, BHLA, ALMF, &c. with plane mirrors, and at the foramina or apertures, pare off the tin or quicksilver, that the eye may see through; place any object in the bottom MI, as a bird in a cage, &c. Here the eye looking through the aperture *hi*, will see each object placed at bottom vastly multiplied, and the images removed at equal distances from one another. Hence, were a large multangular room in a prince's palace lined with large mirrors, over which were placed pellucid glasses to admit the light, it is evident the effect would be very surprizing and magnificent.

This is a very diverting and useful part of knowledge: the phenomena arising from the effects of the instruments that have been invented in this art are surprizing, even to those who knew the reasons of the phenomena they exhibit: but many of those who are ignorant thereof, have thought that those wonderful phenomena were produced by divination; and those crafty knaves, called conjurors or cunning men, have often had recourse to catoptric instruments, to help on the business of more profoundly deceiving ignorant people that came to them to foretell events.

CATOPTRIC DIAL, a dial that exhibits objects by reflected rays. See REFLECTING DIAL.

CATOPTRIC TELESCOPE, a telescope that exhibits objects by reflection. See the article REFLECTING TELESCOPE.

CATTLE, *Pecora*, an order of quadrupeds, for the characters of which, see the article PECORA.

Black CATTLE, the same with the ox-kind. See the article BOS.

CATUS-PARDUS, or **CATUS MONTANUS**, in zoology. See the article CAT of the Mountain.

CAVA, or **VENA CAVA**, in anatomy, a vein arising with a large sinus from the right auricle of the heart. It there sends out a vein to the heart itself, called the coronary vein, and is divided into two trunks, a superior and an inferior; from the superior trunk of the vena cava there arise the following veins; the azygos, the bronchial, the mediastinal, the superior diaphragmatic, and the subclavians: the inferior trunk of the vena cava is remarkable for the valves, and from this arise the diaphragmatic, or inferior phrenic veins, the renal veins, the spermatic, the sacra, and the iliacs. See VEIN, and each of these under its proper head.

CAVALIER, in fortification, an elevation of earth, of different shapes, situated ordinarily in the gorge of a bastion, bordered with a parapet, and cut into more or less embasures, according to the capacity of the cavalier.

Cavaliers are a double defence for the faces of the opposite bastion: they defend the ditch, break the besiegers galleries, command the traverses in dry moats, scour the salient angle of the counter-scarp, where the besiegers have the counter-batteries, and inflade the enemies trenches, or oblige them to multiply their parallels: they are likewise very serviceable in defending the breach, and the retrenchments of the besieged, and can very much incommode the intrenchments which the enemy make, being lodged in the bastion.

CAVALIER, in the manege, one that understands horses, and is practised in the art of riding them.

CAVALRY, a body of soldiers that charge on horseback, and may properly be called the right arm of the army: they are of great service in disturbing the enemy by their frequent excursions, in intercepting convoys, and destroying the country.

The cavalry is divided into squadrons, and encamp on the wings of the army. Too great a number of cavalry may prove prejudicial to an army; for as they consume a great deal of forage, they may oblige a general to decamp from an advantageous post.

CAVAZION, or **CAVASION**, in architecture, the hollow trench made for laying the foundation of a building, which, according to Palladio, ought to be one-sixth part of the whole building.

CAUCALIS, in botany, a genus of plants, the universal flower of which is difform and radiated; the proper flower of the disk is male, small, composed of five inflexocordated equal petals; the proper flavour of the radius is hermaphrodite, and composed of five inflexocordated unequal petals, the exterior one being larger than the rest and bifid: the fruit is of an oblate-oblong figure, striated longitudinally, with rigid scabrous bristles: the seeds are two, oblong, convex on one side and armed with prickles in order of the striae, and plane on the other side.

There are several species of this genus, five or six of which grow wild in England, and are most of them biennial.

CAUDA, in a general sense, denotes the tail of an animal. See the article **TAIL**.

CAUDA DRACONIS, in astronomy, the dragon's tail, known by this character γ , which is the name of the moon's descending node. See the article **NODE**.

CAUDA LEONIS, the lion's tail in astronomy, a star of the first magnitude in the constellation leo. See the article **LEO**.

CAVEA, or **CAVEER**, or **CAVIARY**, the spawn,

of hard roes of sturgeon, made into small cakes, an inch thick, and of an hand's breadth, salted, and dried in the sun. This sort of food is in great repute throughout Muscovy, because of their three Lents, which they keep with a superstitious exactness; wherefore the Italians settled at Moscow drive a very great trade in this commodity throughout that empire, because there is a prodigious quantity of sturgeon taken at the mouth of the Wolga, and of the other rivers which fall into the Caspian sea. There is a pretty large quantity of this commodity consumed in Italy; and they are very well acquainted with it in England and France, where it is reckoned no despicable dish.

The French and Italians get the cavear from Archangel, but they seldom get it at the first hand, for they commonly buy it of the English and Dutch.

CAVEAT, in law, a kind of process in the spiritual courts, to stop the proving of a will, the granting letters of administration, &c. to the prejudice of another. See **PROBATE**.

It is also used to stop the institution of a clerk to a benefice.

CAVEATING, in fencing, is the shifting the sword from one side of that of your adversary to the other.

CAVEDO, in commerce, a Portuguese long measure, equal to 27, $\frac{1}{1000}$ English inches.

CAVERNOSÉ, among anatomists, an appellation given to several parts of the body, on account of their spongy structure: thus the cavernosa corpora of the penis are two spongy bodies, made up of a number of small caverns or cells. These are the two bodies which constitute the penis; they arise distinct and separate on each side of the ossa pubis, as it were from peculiar thalami: after this they join, and, in that original state, are carried into the glans. If any liquid matter be impelled into these, or if they be inflated, the penis becomes rigid. These two bodies are also termed corpora spongiosa.

CAVESON, or **CAVEZON**. See the article **CAVEZON**.

CAVETTO, in architecture, a round concave moulding, which has a quite contrary effect to the quarter round; the workmen call it mouth, when in its natural situation; and throat, when turned upside down. The cavetto is but half a scotia, and therefore should not be confounded with it, as some architects do.

CAVEZON, in the manege, a sort of noseband, either of iron, leather, or wood, sometimes flat, and at other times hollow or twisted, clapped upon the nose of a horse, to wring it, and so forward the supplying and breaking of the horse.

An iron cavezon is a semicircle or band of iron, consisting of two or three pieces joined by hinges, and mounted with a head-stall, a throat-band, and

two straps or reins, with three rings; one rein passes through the middle ring, when we mean to make a horse work round a pillar; through the two side-rings we pass the two reins, which the rider holds in his hand, or makes fast to the saddle, in order to keep the horse's head in subjection, &c.

CAVIN, in the military art, a natural hollow, fit to lodge a body of troops: if there happen to be any near a place besieged, it is of great use to the besiegers; for by the help of such a place they can open the trenches, make places of arms, or keep guards of horse, without being in danger of the enemy's shot.

CAUK, or **CAWK**, a term used among miners, for a coarse sparry stone, of a white colour, found in the lead-mines. See the article **SPAR**.

CAUL, in anatomy, a membranaceous part of the abdomen, covering the greatest part of the guts, usually furnished with a large quantity of fat, placed under the peritonæum, and immediately over the intestines, called by some authors rete, or reticulum, from the number of holes appearing in it, when raised, and giving it the resemblance of a net: but it is most frequently called omentum. See the article **OMENTUM**.

CAUL is also a little membrane, found on some children, encompassing the head when born.

Some take this to be only a fragment of the membranes of the foetus, which generally break at the birth of the child.

CAULICOLES, or **CAULICOLI**, are eight lesser branches or stalks in the Corinthian capital, springing out from four greater or principal cauls, or stalks.

The eight volutes of this order are sustained by four cauls, or primary branches of leaves, and from which these caulicoles, or lesser foliage arise.

CAULIFEROUS, an appellation given to such plants as have a perfect caulis, or stem. See the article **CAULIS**.

CAULIFLOWERS, in gardening, a much esteemed species of the brassica, or cabbage. These plants, like the cabbage, are propagated from seed, and are produced here in great quantities in May, June, and July, far superior to those raised in any other part of Europe; also considerable numbers are produced in autumn, which if the season proves mild continue good till December. The season for sowing is the month of August, even on a particular day with some, generally the twentieth; for if the seeds are sown a week sooner, it is a great chance if they do not run before the proper season for flowering, and if sown so much later, they will be too small at the season for planting out. An old cucumber, or melon bed, is best to receive the seeds, lightly covering them with rich earth, observing to water and shade them in hot weather, to promote their vegetation. In about a week the plants will appear, when the coverings should be taken off by

degrees, for they should not be exposed to the sun too much at first. In about a month after sowing, the plants will be fit to be pricked out on another old bed, at the distance of about two inches, observing to water and shade them till they have got fresh root, after which too much wet should be avoided, as it would greatly damage them. On this bed they may continue till the middle of October, when they should be removed to where they are to stand the winter. Those for the first crop are generally planted under bell or hand-glasses, two under each. Others are reserved under cucumber frames, and transplanted in a good rich land, about the latter end of February, and some are placed under a south wall, where, if the winter is not very severe, they escape pretty well in common. These must be planted out in the spring, at about two feet and a half asunder, which is the proper distance for the others.

In the month of January, it is not amiss to sow on a slight hot-bed, hardening the plants by degrees: these make not a bad substitute, when the others might either by running, or other accidents, have failed; but in case it has not so happened, these will come in after the others, whereby their season is lengthened.

The time for sowing cauliflower seeds, which are to be expected in autumn, is about the middle of May, which being transplanted, &c. will produce very good flowers, from Michaelmas until Christmas, if the season is favourable.

When cauliflowers begin to fruit, they must be carefully watched, and some of the inner leaves broke over them, in order to shade them from the sun, which would otherwise turn them yellow. Some of the closest and largest should be reserved for seed, and when they shoot out for blowing, should be fastened to sticks to prevent their being blown down, and when the seed is ripe, should be cut, dried, and laid by till wanted. For the general characters of this species, see the article **CABBAGE**.

CAULINE, in a general sense, denotes anything belonging to the caulis or stalk of plants. See the article **CAULIS**.

CAULINE LEAF, among botanists, that growing from the stalk of a plant.

CAULIS, among botanists, denotes the stalk of herbaceous plants: this, in trees, is called *caudex*, or trunk; and, in grasses, *culmus*, or stem.

CAULKING, amongst shipwrights, the act of driving a quantity of oakum, i. e. old ropes untwisted and softened, into the seams of the planks, or between them where they are joined, in order to keep out the water: after the oakum is driven very hard into these seams, it is covered with hot melted pitch, to prevent the water from rotting it.

CAUSA MATRIMONII PRÆLOCUTI, in common law, a writ that lies where a woman gives land

land to a man in fee, to the intent he shall marry her, and she refuses to do it in a reasonable time, being thereunto required by the woman: and in such case, for not performing the condition, the entry of the woman into the lands again has been adjudged lawful.

The husband and wife may sue this writ against another who ought to have married her.

CAUSA NOBIS SIGNIFICES, in law, a writ directed to the mayor of a town, &c. who being by the king's writ commanded to make seisin of lands to the king's grantee, delays so doing. This writ requires him to shew cause why he makes delay.

CAUSALTY, among metaphysicians, the action or power of a cause in producing its effect.

It is a dispute among the school-philosophers, whether and how the causality is distinguished from the cause and the effect? Some hold it a mode or modal entity, superadded to the cause, &c. others contend for its being the cause itself. See the article **CAUSE**.

CAUSALTY, among miners, denotes the lighter, sulphureous, earthy parts of ores, carried off in the operation of washing.

This, in the mines, they throw in heaps upon banks, which, in six or seven years, they find it worth their while to work over again. See **ORE** and **WASHING**.

CAUSE, *Causa*, that from whence any thing proceeds, or by virtue of which any thing is done: it stands opposed to effect. We get the ideas of cause and effect, says Mr. Locke, from our observation of the vicissitude of things, while we perceive some qualities or substances begin to exist, and that they receive their existence from the due application and operation of other beings. That which produces is the cause, and that which is produced, the effect: thus fluidity in wax is the effect of a certain degree of heat, which we observe to be constantly produced by the application of such heat.

First CAUSE, that which acts of itself, and of its own proper power or virtue: God is the only first cause in this sense.

Second CAUSES, are those which derive the power and faculty of action from a first cause: these are improperly called causes, in regard they do not, strictly speaking, act at all, but are acted on: of this kind are all those that we term natural causes.

Philosophers are divided as to the action whereby second causes produce their effects: some maintain, that the causality cannot be produced, since it is that which produces: others will have them to act truly by their action; but they are at a loss still about that action: some do not allow that corporeal substances can produce any thing but accidents: the system of Avicenna is, that God produces, immediately, a most perfect spiritual substance; this

produces another, less perfect; that, a third; and thus to the last; which last produces all the corporeal substances; and those corporeal substances, accidents: as to the manner of the agency, some maintain, that the substantial form of second causes produces forms, and the accidental ones, accidents: others, that forms produce other forms; and others, that accidents alone are capable of producing accidents and forms.

Causes are distinguished, by the schools, into efficient, material, final, and formal.

Efficient CAUSES are the agents employed in the production of any thing.

Material CAUSES, the subjects whereon the agents work, or the materials whereof the thing is produced.

Final CAUSES are the motives inducing an agent to act; or the design and purpose for which the thing was done.

Lord Bacon says, that the final cause is so far from being serviceable, that it corrupts the sciences, unless it be restrained to human actions: however, continues he, final causes are not false, nor unworthy of inquiry in metaphysics: but their excursions into the limits of physical causes hath made a great devastation in that province; otherwise, when contained within their own bounds, they are not repugnant to physical causes.

Formal CAUSE, the change resulting from the action; or that which determines a thing to be this, and distinguishes it from every thing else: thus, the soul is held the formal cause of man.

Causes are again distinguished into physical and moral.

Physical CAUSE, that which produces a sensible corporeal effect; as the sun is the physical cause of light; others define it, that which produces its effect by a physical virtue.

The Cartesians resolve all physical causes into occasional ones.

Occasional CAUSES, therefore, are only the occasions, not the direct causes of their effects. See the article **OCCASION**.

The soul, say these philosophers, is not able to act on the body, nor the body reciprocally on the soul: to keep up an intercourse between them, God, on occasion of the motion of the body, impresses a sensation on the soul, and on occasion of a sentiment of the soul, impresses a motion on the body: the motions therefore of the soul and body are only occasional causes of what passes in the one or in the other: thus, say they, the stroke or percussion is only the occasional cause of the motion produced in the body struck: it is God who is the direct efficient cause, &c.

Moral CAUSE, that which produces a real effect, but in things immaterial; as repentance is the cause of forgiveness. A moral cause is also defined, that which determines us, though not necessarily to do, or

or not to do any thing; as advice, intreaties, commands, menaces, &c.

It is to be observed, that in this sense, a moral cause is only applicable to a free intelligent agent: it is also observable, that the latter notion of a physical, as well as a moral cause, is the most just, clear, and distinct.

Causes are again distinguished into universal, or particular; principal, or instrumental; total, or partial; univocal, equivocal, &c.

CAUSE, among civilians, the same with action. See ACTION.

CAUSEWAY, or CAUSEY, a massive body of stones, flakes, and fascines; or an elevation of fat viscous earth, well beaten; serving either as a road in wet marshy places, or as a mole to retain the waters of a pond, or prevent a river from overflowing the lower grounds.

CAUSTICS, in physic, an appellation given to medicines, of so hot and fiery a nature, that being applied, consume, and, as it were, burn the texture of the parts like hot iron.

Caustics differ from cauteries, in that they perform their effects slower, and with less force and pain: they are used to eat off proud fungous flesh; they also penetrate within hard callous bodies, and liquify the humours; and are particularly applied in abscesses and imposthumations; to eat through to the suppurated matter, and give it vent; sometimes also to make issues, in parts where cutting is difficult or inconvenient.

Caustics are generally divided into four sorts, the common stronger caustic, the common milder caustic, the antimonial caustic, and the lunar caustic.

The stronger caustic is prepared, by boiling to a fourth part any quantity of the lees of almond-soap, adding lime, that has been kept in a vessel pretty close stoppt for several months; the lime is a to be added till all the liquor is absorbed, and the whole reduced to a paste, which is to be kept in a vessel well stoppt.

The common milder caustic is prepared, by taking equal parts of soft soap, and fresh quick-lime, and mixing them at the time of using.

The antimonial caustic is prepared thus: take of antimony one pound, of corrosive sublimate, two pounds; and being reduced separately into powder, mix them well, and distil them in a retort with a wide neck, in a gentle heat of sand; let what ascends into the neck of the retort be exposed to the air, that it may run into a liquor.

The method of preparing the lunar caustic is as follows: dissolve pure silver by a sand-heat, in about twice its weight of aquafortis; then dry away the humidity with a gentle fire; afterwards melt it in a crucible, that it may be poured into proper moulds, carefully avoiding over much heat, lest the matter should grow too thick.

CAUSTIC CURVE, in the higher geometry, a curve found by the concurrence or coincidence of the rays of light, reflected from some other curve. See CATACAUSTIC and DIACAUSTIC.

CAUSTIC GLASSES, the same with burning-glasses. See BURNING-GLASS.

CAUSUS, or BURNING-FEVER, a species of continual fever, accompanied with a remarkable inflammation of the blood. The principal symptoms are a heat almost burning to the touch, the breath extremely hot, a dryness of the whole skin, the tongue parched and rough, and an unquenchable thirst. See FEVER.

CAUSWAY, or CAUSEWAY. See the article CAUSEWAY.

CAUTERIZATION, the application of cauteries to any part of the body. See the next article.

Cauterization with moxa is wonderfully extolled by some as the most effectual means to extirpate the gout; but it is at present in disuse, and not without reason; for, besides the acute pain which it creates, it is frequently found to have little or no effect. This cauterization, however, is said to be at present in use among the Arabians; and the Japonese and Chinese have it in so great esteem, that it makes one of their chief remedies.

CAUTERY, in surgery, a medicine for burning, eating, or corroding any solid part of the body.

Cauteries are distinguished into two classes, actual and potential: by actual cauteries are meant red-hot instruments, usually of iron, which are applied to many parts and disorders: and by potential cauteries are understood certain kinds of corroding medicines. See the article CAUSTICS.

Cauteries have manifold uses; for they not only destroy the dead parts of carious bones, remove cancers, schirri, excrescencies, carbuncles, and mortified parts; but they are also used to make issues and setons, to stop hæmorrhages in wounds and amputations; and, lastly, to remove an amaurosis, epilepsy, sciatica, with pains in the teeth and other parts.

For the right application of cauteries, various observations are necessary: 1. The size and figure of the cautery should correspond to that of the disordered part. 2. It is necessary to secure the sound parts from the cautery, to prevent giving more than necessary pain. 3. When the instrument is sufficiently hot, it is to be applied, and strongly impressed upon the disordered part, till the bottom of it appears found. To effect this more speedily, it will be necessary to have several cauteries in readiness, a caution more especially to be observed in carious bones and large hæmorrhages.

Several physicians have observed, that cauteries have succeeded in apoplexies, when all other remedies have failed. But for the part to which the cautery

is to be applied, there are various opinions ; some prefer the occiput ; some the nape of the neck, between the first and second vertebrae ; some the meeting of the coronal and sagittal sutures ; and others pitch upon other parts. Misticchellius, an Italian writer, asserts, that no part can be so proper for cauterizations in apoplexies, as the soles of the feet.

CAUTING-IRON, in farriery, an iron with which farriers cauterize or sear those parts of an horse that require burning.

CAUTION, *Cautio*, in the civil and Scotch law, denotes much the same with what, in the law of England, is called bail. See the article **BAIL**.

CAUTIONE ADMITTENDA, in law, a writ which lies against a bishop that holds an excommunicated person in prison for contempt, after he has offered sufficient caution or security to obey the orders of the church. On receipt of this writ, the sheriff warns the bishop to take caution.

CAXOU, among miners, denotes a chest of any ore ready prepared for refining.

CAZEMATE, or **CASEMATE**, in fortification, a certain retired platform in the flank of a bastion, for the defence of the moat and face of the opposite bastion. Sometimes there are three such platforms one behind another, the uppermost of which is on the terre plain of the bastion, which makes the other two be called *places basses*, or low places. They are covered from the enemy's batteries by a work of earth added to the angle of the shoulder, of a circular and sometimes of a square form, called shoulder, orillon, or epaulement. See **ORILLON**, &c.

It is very seldom that cazemates are used now a-days, because the enemies batteries are apt to bury the cannon they contain under the ruins of their vaults ; besides that, the smoke with which they are continually filled, renders them insupportable to the engineers. It is for this reason that the latter engineers make them open at top, contenting themselves with fortifying them with a parapet.

CASEMATE is also used for a well with several subterraneous branches dug in the passage of the bastion, till the miner is heard at work, and air given to the mine.

CAZERN. See the article **CASERN**.

CEANOTHUS, in botany, a genus of pentandrious plants, whose flower consists of a monophyllous turbinate calyx, with five roundish equal petals, which spread open, and are less than the cup. It contains five erect subulated filaments, topped with roundish antheræ. The fruit is a dry berry, with three cells, each containing an ovated solitary seed.

CEDAR of Barbadoes. See **JUNIPERUS** and **MAHOGONY**.

CEDAR of Busaco. See the article **CUPRESSUS**.

CEDAR of Virginia and Bermudas. See **JUNIPERUS**.

CEDAR of Libanus, a large coniferous tree, which pushes out branches at the distance of ten or twelve feet from the ground : these are large and spreading. Its leaves are acute and ever-green, standing upright. The fruit, which grows erect, are like those of the pine-tree, of which it is a species ; except that it is more obtuse, and its rind thinner and smoother.

There are still some cedars on mount Libanus, but in small number, above and to the east of Biblos and Tripoli. There are none to be seen any where else on those mountains. But it is very probable that there were a great many more formerly, since their timber was used in so many considerable works. There are some cedars also growing in several parts of Africa, in the Isle of Cyprus, and in that of Crete or Candia. Josephus, the Jewish historian, asserts, that Solomon planted so large a quantity of cedars in Judea, that they were as numerous as the sycomore-trees, which are very common in that country.

Mr. Miller observes, that what we meet with in the Scripture of the lofty cedars can be no ways applicable to the stature of this tree ; since by the experience of those we have now growing in England, as also from the testimony of several travellers who have visited those few remaining trees on Mount Libanus, they are not inclined to grow very lofty, but, on the contrary, extend their branches very far : to which the allusion made by the Psalmist agrees very well, when he is describing the flourishing state of a nation : " They shall spread their branches like the cedar trees."

The wood of this famous tree is accounted proof against all putrefaction of animal bodies. This wood is also said to yield an oil, which is famous for preserving books and writings ; and the wood is thought to continue above a thousand years sound. It is likewise recorded, that, in the temple of Apollo at Utica, there was found timber of near two thousand years old. And the statue of the goddess, in the famous Ephesian temple, was said to be of this material also, as was most of the timber-work of that glorious structure.

This sort of timber is very dry, and subject to split ; nor does it well endure to be fastened with nails ; therefore pins of the same wood are much preferable.

Bastard CEDAR, in botany, the English name of the theobroma. See the article **THEOBROMA**.

White CEDAR, a name given to a species of cupressus. See **CUPRESSUS**.

CEDRELA, in botany, a genus of pentandrious plants, whose flower is pentapetalous, and funnel-shaped, with five subulated filaments, topped with oblong antheræ. The fruit is a roundish woody quinquelocular capsule, with five deciduous valves, and contains a number of fleshy seeds.

CEDRIA, among physicians, the gum or resin which

which issues from the cedar. Its good qualities consist in its being fat, thick, transparent, and that, when poured out, it falls by equal drops.

CEGINUS, in astronomy, a fixed star of the third magnitude, in the left shoulder of the constellation Bootes. For its right ascension, declination, variation, &c. see the constellation **BOOTES**.

CELLING, in architecture, is the lathing and plastering at the top of a room, upon the underside of the joists, but up for that purpose, and called ceiling-joists, if it be in a garret. These plastered ceilings are much used in England, beyond all other countries, and they have these conveniences with them; they make the room much lighter, are excellent against raging fire, they stop the passage of the dust, and lessen the noises overhead, and in summer-time they make the rooms somewhat cooler.

CELANDINE the Greater, *Chelidonium*, in botany, a plant with fibrous hairy roots. The leaves are of a bright green colour on the upper side, and bluish underneath; these are longish and divided to the rib into roundish indented portions, of which those at the extremities are much larger than the others: these leaves contain a bright yellow juice, as does likewise the stalks, which are knotty, fistulous, brittle, and branched, with leaves alternately placed. The flowers are yellow and tetrapetalous, coming out in clusters. The filaments are plain and numerous, topped by oblong, compressed, twin anthers; and the fruit is a cylindraceous pod of one or two valves, containing a number of ovated, shining, black seeds. This plant flowers in May, and grows naturally in many parts of England; it is by all allowed to abound with a sharp acrid salt, and is therefore recommended as a powerful aperient and attenuant: it is judged to be a specific against the jaundice, scurvy, and all obstructions and disorders of the viscera.

Half a dram, or a dram of the dried root in powder, or an infusion in wine or water of a dram, or a dram and a half of the fresh root, or three or four drops of its saffron-coloured juice, in any convenient vehicle, are directed for a dose; but great caution is requisite in the internal use of a medicine so acrimonious and irritating.

Among us it is chiefly used by common people for some external purposes, as the destroying warts, cleansing foul sores, and removing clouds, films, and specks from the eyes. For this last intention the juice should be largely diluted in milk, it being of itself much too sharp to be applied with safety to so tender an organ.

CELANDINE the Lesser, or pilewort, in botany, a small plant with roundish, smooth, shining, green leaves, set in long pedicles, and slender procumbent stalks, bearing bright gold coloured flowers. The root consists of slender fibres, with a number of tubercles, or little knobs among them. It is perennial, flowers in April, and grows wild in hedges

and moist meadows. The leaves of this plant are reckoned antiscorbutic, and the roots are celebrated as a specific against the piles, though perhaps without any good foundation. For the generical characters of this plant, see the article **RANUNCULUS**, of which it is a species.

CELARENT, in logic, a mode of syllogism, wherein the major and conclusion are universal negative propositions, and the minor an universal affirmative. As

CE No man that is a hypocrite can be saved:

LA Every man who with his lips only cries Lord, Lord, is a hypocrite:

RENT Therefore, no man who with his lips only cries Lord, Lord, can be saved.

CELASTRUS, in botany, a genus of plants, whose corolla consists of five equal, oval, patent, sessile petals, with their ends turned back: the fruit is a coloured, oval capsule, obtusely trigonal, gibbous, formed of three valves, and containing three cells, in each of which are small, oval, coloured seeds, smooth, and half covered by a calyptra, which is also coloured, and has an unequal rim, divided into four segments.

CELERIAC, in botany, a species of the apium. It differs from the common celery, by having a turnip-shaped root, which is the part used in cookery: also it is distinguished by the colour of the stalks, which are brown; whereas those of common celery are green when not blanched.

CELERY, *Apium*, in botany, a well-known plant, much used in soups, and for other culinary purposes, propagated by seeds, which should be sown at two or three different times. The first sowing may be in March, on a gentle hot bed, the next in April, and the last sowing in May. When the plants of the first sowing are of sufficient size to prick out, some beds of rich earth should be prepared to receive them. Here they may continue until May or June, when they may be transplanted into trenches, (well prepared with rotten dung) where they are to perfect themselves for use; these trenches should be made about three feet asunder, and as the plants advance in height, the earth should be carefully laid up against them at different times, in dry weather, in order to whiten and make them more tender, observing not to cover their hearts. Those of latter sowing are to be managed in the same manner, allowing for the different time. This plant is a common winter salad, and much esteemed for its generical characters. See the article **PARSLEY**.

CELERITY is the velocity or swiftness of any body in motion; and it is defined to be an affection of motion, by which any moveable body runs thro' a given space in a given time. See **VELOCITY** and **MOTION**.

CELESTINS,

CELESTINS, in church-history, a religious order of Christians, reformed from the Bernardins by pope Celestin V. Their rules are divided into three parts; the first, of the provincial chapters, and the elections of superiors; the second contains the regular observances; and the third, the visitation and correction of the monks.

The celestins rise two hours after midnight to say mattins: they eat no flesh at any time, except when they are sick: they fast every Wednesday and Friday, to the feast of the exaltation of the Holy-cross; and from that feast to Easter, every day.

CELIAC, or **COELIAC PASSION**, a sort of diarrhæa, or flux of the belly, wherein the aliment comes away either crude or chylified, instead of excrements. See the article **COELIAC**.

CELIBACY, the state of unmarried persons, to which, according to the doctrine, or at least the discipline, of the church of Rome, the clergy are obliged.

In the church of England, the marriage of the clergy was generally practised to the end of the tenth age, and in a great measure to the beginning of the twelfth.

That celibacy has no pretence of divine or apostolical institution, seems no difficult point to prove: whence it is, at first, hard to conceive from what motive the court of Rome persisted so very obstinately to impose this institution on the clergy. But we are to observe, that this was a leading step to the execution of the project formed of making the clergy independent of princes, and rendering them a separate body, to be governed by their own laws. In effect, while priests had children, it was very difficult to prevent their dependence upon princes, whose favours have such an influence on private men; but having no family, they were more at liberty to adhere to the pope.

CELIODOGRAPHY, κηλυσ, a spot, and γραφω, I describe. See **SUN**, **MOON**, &c.

CELL, *Cella*, a little apartment or chamber, such as those wherein the ancient monks, solitaries, and hermits lived in retirement.

Cells are still retained in divers monasteries. Thus the dormitory is frequently divided into so many cells. The Carthusians have each a separate house, which serve them as a cell.

The hall wherein the Roman conclave is held is divided by partitions into divers cells for the several cardinals to lodge in.

CELLS are also the little divisions in honeycombs, which are always regular hexagons. See **COMB**.

CELLS, in botany, the hollow places between the partitions in the pods, husks, and other seed-vessels of plants. According as there is one, two, three, &c. of these cells, the vessel is said to be unilocular, bilocular, trilocular, &c.

CELLS, in anatomy, little bags or bladders where fluids or other matters are lodged, called *loculi*, *cellulæ*, &c.

CELLAR, the lowest room in a house, the arches of which are mostly level with the surface of the ground on which the house stands, or but very little higher. In ancient writers, cellar denotes the same with *cella*, viz. a conservatory of eatables or drinkables. A cellar differs from a vault, as the latter is supposed to be deeper than the vault. See **VAULT**.

CELOSIA, in botany, a genus of plants, the flower of which consists of five lanceolated, acuminate, erect, rigid, and permanent petals; the fruit is a globose capsule, surrounded with a corolla, with one cell opening horizontally, and containing several roundish emarginated seeds.

A species of this genus is the *amaranthus* coxcomb, a well-known beautiful plant; it is a native of China, and is here one of the principal ornaments of the flower-garden. As the raising and management of this differs so little from the *amaranthus*, we must refer the reader to that article. See **AMARANTHUS**.

CELSIA, in botany, a genus of plants, the flower of which is monopetalous, with a plain limb and roundish segments: the fruit is a roundish capsule, compressed at the top, acuminate, adhering to the cup, with two cells, containing several small angulated seeds.

CELTIS, the lote or nettle-tree, in botany, a genus of polygamious plants, whose flowers are male, hermaphrodite, and apetalous. The hermaphrodite consists of a monophyllous calyx, divided into five parts, and contains five short filaments topped with thick quadrangular antheræ. The fruit is a globose, unilocular drupe, inclosing a roundish nut.

CEMENT, or **CÆMENT**, in the general sense, any glutinous substance capable of uniting and keeping things together in close cohesion.

Cements require to be of various compositions and different with respect to the nature of the ingredients, according to the different manner in which they are to be applied, and the substances they are to conjoin. The kinds of cement used for common purposes pass under the denomination of glue, size, paste, and lutes. See **GLUE**, **SIZE**, **PASTE**, and **LUTES**.

CEMENTATION, or **CÆMENTATION**, in a general sense, the corroding of metals in a dry form, by means of the fumes of acid salts.

It is performed in the following manner. After the copper has been separated as much as possible by copelling, a stratum of salts of about half an inch in thickness is spread in the bottom of the cement-pot; over this are laid thin plates of gold, then another stratum of salts, and so on alternately, till the pot be filled within half an inch of the
brim.

brim. This being done, the pot is covered up, and encompassed with fire, which should be made gradually fiercer and fiercer; and in sixteen or twenty hours after they have been red-hot, entirely removed, that every thing may cool by degrees. Then the pots are to be opened, the salts taken out, and if it is grown too hard, to be softened by a sprinkling of hot water. The plates of gold must be washed in hot water, and the water renewed, till it be free from all saline taste; for the salts, together with the metal they have corroded, will be contained in the plates of gold. The gold must be tried with the touch-stone, or some more certain method, to know if it has the degree of fineness required; and if it is not pure enough, it must be cemented a second time, and, if necessary, with stronger salts.

CEMETERY, *Coemeterium*, a place consecrated, or set apart for burying the dead. See the article **CEMETERY**.

CENEGILD, an expiatory mulct that was formerly paid by one who killed another, to the kindred of the deceased.

CENOBITE, or **COENOBITE**. See the article **COENOBITE**.

CENOTAPH, *νεκροταφιον*, in antiquity, a monument erected in honour of the dead, but not containing any of their remains. Of these there were two sorts. One erected for such persons as had been honoured with funeral rites in another place; and the second sort, for those that had never obtained a just funeral.

The sign whereby honorary sepulchres were distinguished from others, was commonly the wreck of a ship, to denote the decease of the person in some foreign country.

CENSER, a sacred instrument made use of in the religious rites of the ancients. It was a vase, containing incense to be used in sacrificing to the gods. There is the representation of one in Montfaucon's *Antiquities*, under the figure of a shallow cup with a lid to it, and chains running through small handles. Censers were likewise in use among the Jews, as we find in 1 Kings vii. 50. "Solomon, when he prepared furniture for the temple of the Lord, among other things made censers of pure gold." The censer is also used in Romish churches.

CENSOR, in Roman antiquity, a magistrate, whose business it was to reform the manners, and to value the estates of the people.

There were two censors first created in the 311th year of Rome, upon the senate's observing that the consuls were generally so much taken up in military actions, as to have no leisure to attend to private affairs. At first they were chosen out of the senate, but after the plebeians had got the consulate open to them, they soon arrived at the censorship. The censors degraded senators upon occasion, made the *princeps senatus*, inspected the management of

private families, relating to education and expence; and, in short, had authority to reprimand and correct any irregularity, and to take care that persons, both in public and private capacity, behaved themselves in a becoming manner. Cicero reduces their functions to the numbering of the people, the correction and reformation of manners, the estimating the effects of each citizen, the proportioning of taxes, the superintendence of tribute, the exclusion from the temples, and the care of the public places.

The office was so considerable, that none aspired to it till they had passed all the rest; so that it was looked on as surprising, that Crassus should be admitted censor, without having been either consul or pretor. It was held at first five years; but Mamercus *Emilius* shortened the term to eighteen months.

After the censors were elected in the comitia centuriaria, they proceeded to the Capitol, where they took an oath not to manage either by favour or disaffection, but to act equitably and impartially through the whole course of their administration: and notwithstanding their great authority, they were obliged to give an account of their management to the tribunes and *ædiles curules*. In process of time, the dignity of this office dwindled very much; under the emperors it sunk to nothing, as their majesties engrossed all the branches of that jurisdiction. The republic of Venice has at this day a censor of manners of their people, whose office lasts six months.

CENSORS of Books are a body of doctors or others established in divers countries to examine all books before they go to press, and to see they contain nothing contrary to faith and good manners.

CENSURE, a judgment which condemns some book, person, or action, or more particularly a reprimand from a superior. Ecclesiastical censures are penalties by which, for some remarkable misbehaviour, Christians are deprived of the communion of the church, or prohibited to execute the sacerdotal office.

CENSUS, among the Romans, was an authentic declaration, made by the several subjects of the empire, of their respective names and places of abode, before proper magistrates in the city of Rome, called censors, and in the provinces censitors, by whom the same were registered.

This declaration was accompanied with a catalogue, or enumeration, in writing, of all the estates, lands, and inheritances they possessed; their quantity, quality, place, wives, children, tenants, domestics, slaves, &c.

The census was instituted by king Servius, and was held every five years. It went through all the ranks of people, though under different names: that of the common people was called census, or lustrum; that of the knights, census, recensio, recognition; that of the senators, lectio, relectio.

Hence, also, census came to signify a person who had

CEN

had made such a declaration ; in which sense it was opposed to incensus, a person who had not given in his estate or name to be registered.

The census among the old Romans was held, as is commonly thought, every five years ; but this must not be taken to be precisely true : on the contrary, Dr. Middleton has shewn, that both the census and lustrum were, for the most part, held irregularly and uncertainly, at very different and various intervals of time.

The census was an excellent expedient for discovering the strength of the state : by it they learned the number of the citizens, how many were fit for war, and who for offices of other kinds ; how much each was able to pay of taxes towards the charge of the war.

The census, according to Salmastius, was peculiar to the city of Rome. That in the provinces was formerly called *profectio* ; but this distinction is not every where observed by the ancients themselves.

CENT, from *centum*, a hundred, used in commerce, to express the profit, loss, interest, brokerage, &c. Thus, a merchant, or tradesman, we say, gained five, ten, or twenty per cent. by such a commodity, which means nothing more, than that he gained five, ten, or twenty pounds by every hundred pounds he laid out in that commodity. Likewise, when a person lends out a sum of money upon interest, it is usual to say, he has lent it out at five per cent. &c. which is nothing more than that the lender is to receive five pounds per year for every hundred pounds he lends, and in proportion for any other quantity. Again, when we employ a broker, factor, &c. to negotiate any business, &c. it is usual to allow such factor, or broker, a fee or perquisite of one-eighth per cent. one-fourth per cent. &c. according to agreement ; which signifies, that the broker is to receive one-eighth of a pound, viz. 2s. 6d. for every hundred pounds he negotiates on your account, &c. We likewise say, the exchange of such a country is so much per cent. Thus we may say, the exchange at Barbadoes at present is thirty-five per cent. which means, that the currency of that island differs from sterling thirty-five pounds in the hundred.

CENTAUR, or **HIPPOCENTAUR**, in ancient poetry, denotes a fabulous kind of animal, half man, half horse.

The Thessalians, who first taught the art of breaking horses, appearing on horse-back to make only one body with the animal on which they rode ; gave rise to the fiction of the hippocentaur.

CENTAUR, or *Centaurus*, in astronomy, a constellation of the southern hemisphere near the Wolf, and by some joined with the Wolf, and called *Centaurus cum Lupo*, but we shall give them separate. In fabulous history we have various opinions with regard to this constellation. Some will have it to be Typhon ; others Chiron, the schoolmaster of

CEN

those three excellent men, Hercules, Achilles, and Æsculapius : unto Hercules he read astronomy, to Achilles music, and to Æsculapius physic, and for his upright life, they say, was turned into this constellation. However, Virgil calls Sagittarius by the name of Chiron, and we rather think it is that sign into which Chiron is translated. Near the hind feet of this constellation are four stars, forming by their position a cross, and by sailors are called the Crofters ; these are not visible in England, nor are many of those in the Centaur. The five below are all that have been observed with any accuracy at the Observatory, though there are more that rise above our horizon, yet they are so small, and it is commonly so hazy in this climate near the earth, that they become invisible.

Order.	Magn.	Name.	Right Ascension.	Distance from Nor. Pole.	Var. in Right Ascen.	Var. in Declination.
1	4.5	<i>i</i>	202.59.59	121.48.56	48.2	18.8

4	4.5	<i>k</i>	204.50.0	120.43.40	48.5	17.8
5	2.3	<i>θ</i>	208.8.38	125.9.4	50.2	17.5

CENTAURIUM Majus, great centaur, in botany, a large plant, with the leaves composed of oblong serrated segments set in pairs on a middle rib, which is edged, in the intermediate spaces, with a serrated margin : the stalk divides, towards the upper-part, into several branches, bearing on the tops round soft fealy heads, from which come forth bluish flosculi, followed by down inclosing the seeds. It is perennial, a native of the southern parts of Europe, and raised with us in gardens.

The root of this plant, of a dark blackish colour on the outside, is internally reddish, and yields, when fresh, a juice of a deep red. It has a slight smell, not agreeable ; and in chewing discovers a viscous sweetness and roughness, with some degree of acrimony. It is reckoned aperient and corroborant, and supposed to be particularly useful in alvine fluxes ; in which intention it has by some been greatly recommended, though apparently much inferior to the root, whose place it was employed to supply, to wit, the true rhapontic. Among us it has long stood discarded from practice, and is now dropped by the colleges both of London and Edinburgh.

CENTAURIUM Minus, lesser centaur, in botany, a small plant, with three-ribbed, somewhat oval leaves, set in pairs on the stalks ; which divide, towards the top, into several branches, bearing umbel-like clusters, of bright red, funnel-shaped flowers, cut into five acute segments, followed by little oblong capsules full of very small seeds. It is annual.

grows wild in dry pasture grounds, and flowers in July.

The leaves and tops of centaury are strong bitters, of scarcely any smell or particular flavour. The seeds also are very bitter; the petals of the flowers, and the roots, almost insipid. The flowery tops are generally made choice of, and are of considerable estimation in the present practice as corroborant stomachic bitters.

CENTER, or **CENTRE**, in a general sense, signifies that point which is equally distant from the extremities of a line, superficies, or solid.

The word is formed from the word *κεντρον*, a point.

CENTER of Attraction, in the new astronomy, is that point towards which the revolving planet or comet is impelled or attracted by the impulse of gravity.

CENTER of a Circle, is a point within the same, from whence all lines drawn to the circumference are equal.

CENTER of a Conic Section, is the point where all the diameters meet.

CENTER of a Dial, is that point in the dial where a line drawn parallel to the axis of the earth intersects the dial planes.

CENTER of an Ellipse, is that point where the transverse and conjugate diameters intersect each other.

CENTER of the Equant, in the old astronomy, is a point in the line of the aphelion, being so far distant from the center of the eccentric towards the aphelion, as the sun is from the center of the eccentric towards the perihelion.

CENTER of gravity is that point about which all the parts of a body, in any situation, balance each other, or are in equilibrio. The particular properties of the center of gravity are as follow:

First, If a body be suspended by this point, as the center of motion, it will remain at rest in any position indifferently. 2. If a body be suspended by any other point, it can rest only in two positions, viz. when the center of gravity is exactly above or below the said point of suspension. 3. When the center of gravity is supported, the whole body is kept from falling. 4. Because this point has a constant endeavour to descend to the center of the earth; therefore, 5. When the point is at liberty to descend, the whole body must descend, or fall either by sliding, rolling, or tumbling down. 6. The center of gravity in regular, uniform, homogenous bodies, as squares, circles, spheres, &c. is the middle point in a line, connecting any two opposite points or angles. 7. In a triangle, it is in a line, drawn from any angle bisecting the opposite, one third of the length of that line, distant from the side, or base bisected. 8. In human bodies, the center of gravity is situated in that part which

is called the pelvis, or in the middle between the hips.

Hence the solutions of many very curious phenomena will be evident, with the least attention; and as the center of gravity is of the greatest consequence to be well understood, being the sole principle of all mechanical motion, it may not be amiss to shew the method of finding that point in any line, figure, or body, which we shall first do theoretically, and then a few examples of performing the same mechanically.

Let MN (Plate XXX. fig. 10.) be any figure or solid body, regular or irregular; C it's center of gravity; and suppose it to be suspended in C upon the horizontal line SC, and the axis of suspension to pass through S, parallel to the horizon and perpendicular to SC. Let all the infinitely small particles of the body be reduced to the line SC, situated respectively in planes perpendicular to SC; and let the magnitude of every two particles of the body taken on different sides of C (as *a* and *g*, *b* and *h*, *d* and *i*, &c.) be reciprocally as their distances from C; then is C still the center of gravity of each corresponding two, as it is of the whole MN. Therefore we have $Caxa = Cg \times g$, that is $SC - Sa \times a = Sg - SC \times g$, or $a + g \times SC = Sa \times a + Sg \times g$. In like manner $b + h \times SC = Sb \times b + Sh \times h$, and $d + i \times SC = Sd \times d + Si \times i$, &c. whence $a + b + d + e + g + h + i + k \times SC = Sa \times a + Sb \times b + Sd \times d + Se \times e + Sg \times g + Sh \times h + Si \times i + Sk \times k$, &c. consequently $SC = \frac{Saxa + Sg \times g + Sb \times b + Sh \times h \&c.}{a + g + b + h \&c.}$

Now if any one of the variable distances, as *Sb* be called *x*, the body MN, *s*; then will $Sb \times b = xs$, and the sum of all the $Saxa + Sb \times b \&c. =$ sum of all the xs , or the fluent of xs : and the sum of all the $a + b + g \&c. =$ sum of the *s*, or the fluent of *s* that is the body MN; therefore $SC = \frac{\text{fluent of } xs}{\text{fluent of } s}$. Therefore

body MN or *s*.
To find the center of gravity; let *s* = line, surface or solid: multiply the fluxion of the line, surface, or solid (*s*) by the distance (of the center of gravity of the generating point, line, or plane) from the axis of suspension; and find the fluent *z*; then $\frac{z}{s} =$ distance of the center of gravity from the point of suspension.

Example I. Let SB be a right line or cylinder, S the point of suspension; SB = *x*; then $z = xs$, and $z = \frac{1}{2}xx$; therefore $\frac{z}{s} = \frac{1}{2}x$, for the distance of the center of gravity SC.

Example II. In the triangle SQD, (fig. 12.) whose point of suspension is S, let SF bisect the

opposite side QD, then the center C is in the line SF; draw AE parallel, and SG perpendicular to QD, put SF = a, SB = x, SI = v, SG = b, QD = b, AE = y. By similar triangles $v = \frac{bx}{a}$, and $\dot{v} = \frac{b\dot{x}}{a}$, $y = \frac{bx}{a}$; then $\dot{z} = x\dot{v} = \frac{bbx\dot{x}}{aa}$; and $z = \frac{bbx^2}{2aa}$. Also $\dot{s} = y\dot{v} = \frac{bbx\dot{x}}{aa}$, and $s = \frac{bbx^2}{2aa}$. Therefore $\frac{z}{s} = \frac{2}{3} \frac{x}{a}$, and when $x = a$, $\frac{z}{s} = \frac{2}{3} a = SC$.

Example III. Let AM (fig. 13.) be the arch of a circle, s its center, AD = b, SE = r, SB = x, AM = v, BM = y. It is evident the center of gravity of any arch AEG is in the line SE that bisects it. Whence $\dot{z} = x\dot{v}$ (by the nature of the circle) = $r\dot{y}$; and $z = -ry$; and the fluent corrected is $z = by - ry$. Whence $\frac{z}{s} = \frac{rb - ry}{v}$, and when $y = 0$, $\frac{z}{s} = \frac{rb}{v} = SC$, the distance of the center of gravity of the arch AEG from S.

Example IV. For the sector of a circle MmS, (fig. 14.) whose center and point of suspensions S; let arch Mm = c, radius SM = r, Mm = a, SQ = x, QDq = v. Then Qq = $\frac{ax}{r}$, and by the last example, the distance of the center of gravity of the arch QDq from S is = $\frac{ax^2}{rv}$, therefore $\dot{z} = \frac{ax^2\dot{x}}{r}$, and $z = \frac{ax^3}{3r}$; therefore $\frac{z}{s} = \frac{ax^3}{3r \times \frac{1}{2} xv} = \frac{2ax^2}{3rv} = \frac{2ax}{3c}$; and when $x = r$, then SC = $\frac{2ar}{3c}$.

Example V. For the circular area PQD, (fig. 15.) Let SD or SE = r, SQ = b, PQ = c, SB = x, PA = v, AB = y, by the nature of the circle $y = \sqrt{rr - xx}$; then $\dot{z} = yx\dot{x} = x\dot{x}\sqrt{rr - xx}$, and $z = -\frac{1}{3} \times \sqrt{rr - xx}^{\frac{3}{2}}$; corrected $z = \frac{rr - bb}{3} - \frac{rr - xx}{3} = \frac{c^3 - y^3}{3}$. Also $s = \text{area PABQ} = \frac{vr \times xy - cb}{2}$; $\frac{c^3 - y^3}{3}$. Also $s = \text{area PABQ} = \frac{vr + xy - cb}{2}$; whence $\frac{z}{s} = \frac{2}{3} \times \frac{c^3 - y^3}{vr + xy - cb} = SC$. And the distance of the center of gravity of the whole PADQ from S is = $\frac{2c^3}{3vr - 3cb}$.

Again in respect of the axis of suspension SD; since the center of gravity of the describing line y,

is in the middle of BA, therefore $\dot{z} = \frac{1}{2} y \times \dot{x} = \frac{rr\dot{x} - x^2\dot{x}}{2}$, whence $z = \frac{r^2x}{2} - \frac{x^3}{3}$. But (in Q, $x = b$, $z = 0$) the fluent corrected is $z = \frac{3rrx - 3rrb - x^3 + b^3}{6}$; therefore $\frac{z}{s} = \frac{1}{3} \times \frac{3r^2x - 3r^2b - x^3 + b^3}{vr + xy - cb}$; and when $x = r$, $\frac{2r^3 - 3r^2b + b^3}{3rv - 3cb} = \text{distance of the center of gravity of the semi-segment PADQ from QD}$.

Example 6. In the parabola $rx = yy$, (fig. 16.) let SP = x, PM = y, then in respect of the axis of suspension ST, $\dot{z} = yx\dot{x} = x\dot{x}\sqrt{rx}$; and $z = \frac{2}{3} x\dot{x}\sqrt{rx}$; and $s = \frac{2}{3} xy = \frac{2}{3} x\sqrt{rx}$; therefore $\frac{z}{s} = \frac{3}{2} x$ the distance of the center from ST.

Again in regard to the axis of suspension SP, because the center of gravity of the describing line is in the middle of MP, therefore $\dot{z} = \frac{1}{2} y\dot{x} = \frac{y^3\dot{y}}{r}$, and thence $z = \frac{y^4}{4r}$; and $s = \frac{2y^2}{3r}$. Therefore $\frac{z}{s} = \frac{3}{2} y$, the distance from SP.

Example VII. For the hyperbolic area BCMP, (fig. 17.) between the asymptotes. Let SP = b, BC = c, SP = x, PM = y, $cb = xy$. Then in regard to the axis SD, $\dot{z} = yx\dot{x} = cb\dot{x}$, and $z = cbx$, but in B, $x = b$, therefore by correction $z = cbx - b^2$. And $\frac{z}{s} = \frac{cbx - b^2}{\text{area BCMP}}$.

Again for the axis of suspension SP, $\dot{z} = \frac{1}{2} y\dot{x} = \frac{cbb}{2xx}\dot{x}$, and $z = \frac{-cbb}{2x}$; corrected $z = \frac{cb}{2} \times c - y$ and $\frac{z}{s} = \frac{cb \times c - y}{2 \text{ area BCMP}}$.

Example VIII. Let AMB (fig. 18.) be an ellipsis, S the center, AS = a, SB = b, SQ = y, QM = x = $\frac{a}{b} \sqrt{bb - yy}$, then for the elliptic space, $\dot{z} = xy\dot{y} = \frac{ay\dot{y}}{b} \sqrt{bb - yy}$; and $z = -\frac{a}{3b} \times \sqrt{bb - yy}^{\frac{3}{2}}$, corrected $z = \frac{abb}{3} - \frac{a}{3b} \times \sqrt{bb - yy}^{\frac{3}{2}}$. Thence $\frac{z}{s} = \frac{ab^3 - a \times \sqrt{bb - yy}^{\frac{3}{2}}}{3b \times \text{area SAMQ}}$.

Likewise for the distance from SB, $\dot{z} = \frac{1}{2} x\dot{y} = \frac{aay}{2} - \frac{aay^2}{2bb}$, and $z = \frac{aay}{2} = \frac{aay^2}{2bb}$; whence $\frac{z}{s} = \frac{3bb^2y - aay^2}{6bb \times \text{area SAMQ}}$.

Example IX. Let SMP (fig. 16.) be the hyperbolic space, transverse = 2a, conjugate = 2b, SP = x, PM = y = $\frac{b}{a} \sqrt{2ax + xx}$, whence

$$\text{whence } xx = 2aa + \frac{aa}{bb} yy - \frac{2aa}{b} \sqrt{bb + yy},$$

$$xx = \frac{aa}{bb} yy - \frac{aayj}{b\sqrt{bb+yy}}; \text{ whence } z = yxx$$

$$= \frac{aa}{bb} y^2 j - \frac{aay^2 j}{b\sqrt{bb+yy}}, \text{ and } z = \frac{aay^3}{3bb}$$

$$- \frac{aay}{2b} \sqrt{bb+yy} + \frac{aab}{2} \times 2.30258 \log.$$

$$y + \sqrt{bb+yy}; \text{ whence } \frac{z}{s} = \frac{z}{\text{area SMP}}$$

= distance from ST.

Then for the distance from SP, we have $z = \frac{yyx}{2} = \frac{bbx}{2aa} \times \frac{2ax + xx}{xx}$, and the

$$\text{fluent } z = \frac{bbxx}{2b} + \frac{bbx^3}{6aa}; \text{ therefore } \frac{z}{s}$$

$$= \frac{3abbxx + bbx^3}{6aa \times \text{area SPM}}.$$

Example X. For the surface of a right cone, (fig. 19.) let SD = f, c = circumference of the base, axis SB = d, SM = v, SF = x. Then it is plain it's center of gravity is in the axis SB.

$$\frac{cx}{d} = \text{circumference of the circle MQ; and}$$

$$\text{by similar triangles } v = \frac{fx}{d}; \text{ therefore } z =$$

$$\frac{cx^2 v}{d} = \frac{cfx^2 x}{dd}; \text{ and } z = \frac{cfx}{3dd}; \text{ also } s =$$

$$\frac{cxv}{2} = \frac{cfxx}{2dd}; \text{ therefore } \frac{z}{s} = \frac{3}{2} x = SC.$$

Example XI. For the cone (or pyramid) SDE, (fig. 19.) let the base = b, the rest as in the last example; then the circle MQ = $\frac{bxx}{dd}$; and

$$z = \frac{bx^3}{dd}, \text{ and } z = \frac{bx^4}{4dd}; \text{ also } s = \frac{bx^3}{3dd};$$

therefore $\frac{z}{s} = \frac{4}{3} x = SC$ the distance of the center of gravity from S.

Example XII. Let SMD (fig. 20.) be a sphere, SP = y, radius = r, c = 3.1416, then y = $\sqrt{2rx - xx}$, and $z = cj^2 xx = 2crxx$; therefore $z = \frac{2crx^3}{3} - \frac{cx^4}{4}$; and s =

$$= crx^2 - \frac{cx^3}{3}; \text{ therefore } \frac{z}{s} = \frac{8rx - 3xx}{12r - 4x}$$

for the distance of the center of gravity from S.

Example XIII. For the spheroid SMD, (fig. 20.) whole center is C, let SC = a, CF = b, SP = x, PM = y, c = 3.1416, then yy = $\frac{bb}{aa} x$

$$2ax - xx; \text{ and } z = cyyxx = \frac{cbb}{aa} x$$

$$2axx - x^2 x; \text{ and } z = \frac{cbb}{aa} \times \frac{2}{3} ax^3 - \frac{1}{4} x^4;$$

$$\text{and } s = \frac{cbb}{aa} \times \frac{ax^2 - \frac{1}{3} x^3}{12ax - 3xx}; \text{ and } \frac{z}{s} =$$

Example XIV. To find the center of gravity of the solid SBDm, (fig. 21.) generated by a partial revolution of the parabola SMD about the axis SB. Let s be the point of suspension, let SB = d, BD = b, SP = x, PM = y, ax = yy, arch Dd = c; then arch Mm = $\frac{cy}{b}$; therefore

$$z = \frac{cyy}{2b} x = \frac{cax^2}{2b}; \text{ and } z = \frac{cax^3}{6b};$$

$$\text{and } s = \frac{cax^2}{4b}, \text{ therefore } \frac{z}{s} = \frac{2}{3} x, \text{ the distance}$$

from ST.

Example XV. Let the hyperbola CM (fig. 22.) revolve round the asymptote SP, and describe an hyperboloid CMB: let SB = b, BC = d, SP = x, PM = y, c = 3.1416. bd = xy; and $z = cyyxx = \frac{bbddcx}{x}$, whence z =

$$bbddc \log. x: \text{ and corrected } z = bddc \log. \frac{x}{b}; \text{ also } s = cyyx = \frac{cbbddx}{xx}; \text{ and } s =$$

$$\frac{cbbdd}{x}, \text{ and corrected } s = cbbdd \times \frac{x-b}{bx};$$

$$\text{therefore } \frac{z}{s} = \frac{bx}{x-b} \times \log. \frac{x}{b} = \text{distance}$$

of the center of gravity of the solid from SA.

To find the center of gravity of bodies mechanically. First let AB (Plate XXXI. fig. 1.) be a body whose center of gravity is to be found. If it be suspended by any part, as A, so as to move freely on the pin at A, and a plumb-line AP hangs from the same pin, its center of gravity must be under, or rather behind that line, because it will fall below the center of motion A. Let the line AB, (fig. 2.) be marked upon the body as in figure, and then suspend the body of any other part, as F, provided that the center of motion be not in the line AB, hang on the plummet at F, and the line FD under the plumb-line, FP will cut the line AB, and shew the center of gravity to be at C; for since it must be both in the AB, and in the line FD, it can only be in the point C, where they intersect.

Let it be remarked, that we have not here considered the thickness of the body; but if we suppose it a piece of board, as the figure represents; then we must only make the experiment on the other side, and as we shall find another point C, just opposite to the first point C. The line which joins these two points is called the axis of gravity, and the middle of that line the center of gravity.

Any body that we consider in mechanics, is only an aggregate of several other bodies or parts; so that the center of gravity of a body, is only the common center of gravity of all the parts; and

consequently several bodies are united in any machine; or if there be any combination of bodies to be sustained, regard is no longer had to the particular centers of gravity of the several bodies which make up the compound, but only to the common center of gravity of the whole. Thus a windmill must be supported under the common center of gravity of all its parts, and its line of direction must fall along the axis of the post round which it moves: and crane upon a wharf, or a dock, where the whole machine turns round, must have the line of direction in its axis.

Let the line *AB*, *fig. 3*, present an even rod or wire, divided into two equal parts at the point *C*, its center of gravity will be at *C*; and if two equal bodies, equally heavy, be thrust on at each end, so as to have their centers of gravity at the same distance from *C*, they will be in equilibrio at the said point *C*, which will then become the common center of gravity, and continue so, whether the bodies approach nearer to, or recede farther from it, in proportion to their masses. The same will happen if the bodies are unequal, as *A* and *b*, *fig. 4*, whose masses are to each other as two and one, provided that the greater body be at *A*, twice as near to the common center of gravity *c*, than the lesser body *b*. And *c* will be the center of gravities of those bodies, though they should move to immense distances from each other, provided their distances from the said point *c*, are reciprocally as their masses, as we said before.

So that when two bodies approach towards, or recede from each other, with velocities reciprocally proportionable to their masses, their center of gravity will remain at rest. And if the bodies being made fast upon the wire, the center of gravity be sustained on a pivot, how swift soever the bodies be made to turn round the center of gravity, and each other, the center of gravity will remain at rest, and the bodies will describe similar circles about it and each other, as in the figure, the one never overpowering the other. If they be carried forward in any manner by any external force acting upon them, in proportion to their masses, their centers of gravity will go forward uniformly in a right line, and move just as if the two bodies were united in one at the said center. And if they be projected, their center of gravity will move in the same curve as projectiles do, whether in their motion they turn round each other, or not. This is evident in the motion of an arrow, of a chain-shot, or bar-shot, and of a stick thrown from the hand, the center of gravity of any of those bodies moving in the same manner as a single ball would do. So the moon and earth, in their motion round the sun, do neither of them describe the *magnus orbis*; but their common center of gravity describes it in the same manner that they would do if they were both united in that point, or in the same manner that the earth alone is

supposed to do it, when these inequalities of motion are overlooked; and provided that their distances from the common center of gravity be reciprocally proportionable to their masses, their distances from each other may be greater or less in any proportion. If there were no other bodies in our system but the earth and moon turning round each other, their center of gravity would always remain at rest.

But since the large body of the sun, by the power of attraction, commands the earth and moon to revolve about itself, it will follow, that the point *c*, (*fig. 5*.) (supposing *A* the earth, and *B* the moon) is that which must describe the *magnus orbis* about the sun, because no other point between *A* and *B* can keep at the same distance from the sun, on account of the mutual revolution of those bodies about that point, at the same time they are carried about the sun.

But to illustrate this farther, let *S* (*Plate XXXI. fig. 5*.) be the sun, and *CDEF*, a part of the earth's annual orbit, *A* and *B* the earth and moon in her conjunction at *C*, in her quadrature at *D*, in her opposition at *E*, and in her last quarter at *F*. During all these motions from *C* to *F*, it is evident that the center of the earth describes an irregular curve *ADAF*, but the center of the moon one, much more so, as being at very unequal distances from the sun *S*, continually increasing and decreasing, and that the point *C* is that alone which is at an equal distance at all times, and therefore describes the circular orbit about the sun.

If three or more bodies united to, or acting upon one another, in any manner proportionable to their masses, be carried about their common center of gravity, that point will be at rest for the same reason, as it will happen in respect of two bodies; because any number of bodies may, in this respect, be reduced to two. Thus, in our system, where the sun and our planets move round their common center of gravity, that center is at rest in the middle of the system. Though we commonly consider the sun as immovable in the middle of the system, because as it has vastly more matter than all the planets together, that center will be always very near the sun's center; which may easily be found by comparing their quantity of matter and distances, thus. Let *ABC* (*fig. 6*.) represent the sun's body on *I* its center. Now since the bulks and distances of the four first planets, viz. Mercury, Venus, the Earth, and Mars, are very inconsiderable in regard of the sun, they would not, if placed in the right line *CG*, remove the common center of gravity between the sun and themselves far from the center of the sun suppose to *L*. But when we come to Jupiter, his bulk and distance give him a considerable momentum, which well, if placed in the same line *CG*, remove the center of gravity from *L* to *I*, a point without the

the surface of the sun's body. Lastly, if we consider Saturn placed in the line CG , with all the rest, his momentum from his great distance and bulk, will be considerable enough to bring the common center of gravity from I to H , at such a distance CK , from the sun's surface as is equal to eight-tenths of the sun's semidiameter SC , or $SC:CK::10:8$. Now it is this point K , which is the fixed and immovable center of the system, about which the sun as well as all the planets move. Thus we see the center of gravity of any body, or system of bodies, is not within the body itself, or any one of the combined bodies; yet we are to have the same regard to its support, descent, or motion, in any direction, as if it was.

Several odd phenomena depend upon the principle of the center of gravity. As for example, the double cone or spindle $ACBD$, (Plate XXXI. *fig. 7.*) being laid on at E , upon the lower parts of the rulers EF , will, of itself move towards EF , though those ends are raised up to the heights FG by the two screws FG , and by that means will seem to move upwards. How high FG may be in proportion to the bigness of the spindle $ABCD$, is easily demonstrated from the rules already laid down.

Again, let AB , (*fig. 8.*) be a rolling lamp, that has within it the two moveable circles DE and FG , whose common center of motion is at K , where their axis of motion cross one another, there point is also their common center of gravity. If to the inward circle you join within side the lamp KC made pretty heavy and moveable about its axis HI , and whose center of gravity is at C , the common center of gravity of the whole machine will fall between K and C , and by reason of the pivot A, B, D, E, H, I , will be always at liberty to descend; and therefore let the whole lamp be rolled along the ground, or moved in any manner, the flame will always be uppermost, and the oil cannot spill. Thus are the compasses hung at sea, and thus should all the moon lanterns be made that are carried before coaches or carriages that go in the night.

Upon the table Tt , *fig. 9.* which has a slit from X to x , set the little image DM in such a manner, that the saw c , which is fastened at one end to the hands of the image, and has a weight W fixed at the other end, may pass through the slit Xx , and the image will stand in an upright posture: then if the head of the image be brought down to A or B , it will imitate the motion of sawing, and vibrate several times in the arc AoB , whilst the weight W , does in the same manner describe the arc VWV , the center of motion of the whole, (that is, of the image, saw, and weight) being at M . The common center of gravity K , does likewise describe the arc LKL , till (after

having several times descended from L on either side) it comes to settle at K , just under the center of motion. If the image had no saw, it would stand upright when set on the table, because its center of gravity C , would then be just over the center of motion M , and some of the image, which is in the line of direction OO would be supported; but the least alteration of position that should move c from over M would throw down the image. Then if the saw c be added, since its center of gravity is at c , the common center of gravity of the man and saw will be at L , and in that case the image with its saw will fall towards X ; but if by means of a curved wire, the heavy weight W be joined to the saw, the common center of gravity of the man, saw, and weight, will be at K , and the line of direction will again be OO , therefore the image will stand in its upright position. If now the image be inclined forwards or backwards, it will, after several vibrations, return to its first position, because the center of gravity always endeavours to descend to K , in doing which it will bring the image upright.

Again, upon the stick SS , (*fig. 9.*) which of itself would fall from the table, because its center of gravity hangs over, suspend the pail p , fixing another stick qp , one end in a notch at p , and the other against the inside of the pail, close to the bottom, and the pail, without any other help, will be supported on the sticks SS , which will not fall from the table, though the pail be afterwards filled full of water, provided the handle of the pail be pretty near the table, and the stick pq long enough to push the pail a little out of the upright.

When the stick SS (*fig. 10.*) is horizontal to the table TdB , c is the common center of gravity of the two sticks SS , and PQ , the pail DQE , and the water contained in it, all which taken together, are to be looked upon as one body, whose line of direction is OO ; and as the part of SS , which is a little behind the bale, or handle B , is in the line of direction, and sustained upon the edge of the table, the whole body above-mentioned cannot fall, for if it did, the part BS must rise at the end S into the position Bs , and PS descend into the position ps , which cannot happen unless the pail rises into the position dqe , bringing up the common center of gravity to c in the arc CeD , which is impossible from gravity alone, without the action of an extrinsical agent.

But if the pail DE be lifted up under the table, and the stick SS inclined above it, so that the whole machine comes into the position ss, pe, qd ; and the stick ss is smooth as well as the table, it then it be left to itself, the whole machine will slide down, and so fall from the table; ss moving in the direction sp , and the common center of gravity cE , tangent to the arc DcC .

Here it is observable, that as oo is now the line of direction, no part in the said body is supported.

These are a few of the curious phenomena that depend on the principles of the center of gravity, and they who are desirous of seeing more, may consult Defagulier's Experimental Philosophy, where they may find great variety, and from whence we have taken some of the above, and likewise some from Mr. Emerson's Fluxions.

CENTER of Magnitude, is that point which is equally distant from all the external parts of any body.

CENTER of Motion, is that point round which a body or machine moves, or endeavours to move, when it cannot or does not move quite round; and in that case all the points of the body describe circles, or arcs of circles about the center of motion. This center may be taken any where, according to the make of the machine.

CENTER of Oscillation, is the point in the axis of a vibrating body, in which, if a small body or particle be placed, it shall perform its vibrations after the same manner in the same time, and with the same angular velocity as the whole body. From the above definition of the center of oscillation, it is easy to understand that it is the very same with the center of percussion, in the body or rod AB , (Plate XXXI. fig. 11.) for since the point G is that in which the forces of all the particles are united to generate motion in the body, and the center of percussion, is that in which alone the motion of the body can be destroyed, it necessarily follows they are both one and the same point; and therefore if AB be of an uniform figure, it will be isochronal, or vibrate in the same time with the common pendulum $FC = AG = \frac{2}{3} AB$. Therefore, since the center of oscillation and the center of percussion is the same, we shall give a general rule with some examples for finding the said central point, under the article **CENTER of Percussion**, which see.

CENTER of Percussion, is that point in the axis of a vibrating body, which striking against an immovable obstacle, the body shall incline to neither side, but rest as it were in equilibrio in that point. This percussive force arises from three sources, viz. 1st, from the mass of matter in the percutient body. 2d, From its gravitating force, in regard to its distance from the center of motion; and 3dly, From the actual velocity of the motion itself.

The two first make the momentum, and this compounded with the latter, constitutes the percussive force.

To find the center of percussion, oscillation, and the center of pressure of any plane immersed in a fluid, and containing that fluid.

As the above three centers are each in the same

point, they consequently are found by the same method, therefore we shall first give one general method for finding the said point, and then give a few examples for finding the same in particular bodies.

Through the point of suspension C , (Plate XXXI. fig. 12.) and center of gravity, draw the axis of the body CO ; and suppose O to be the center of percussion, oscillation, pressure, &c. required. Thro' CO draw the plane in which the center of gravity moves, and imagine the body to be divided into innumerable small prisms, all perpendicular to this plane, and let them be supposed to be reduced to, or situated in the points, where they intersect the plane, and let p be one of those small prisms. Draw pf perpendicular to CO , and pd perpendicular to Cp ; then pd will be the direction of p 's motion, as it revolves about C , and the body being stopped at O , p will urge the point d forward with a force proportionable to its magnitude and velocity, that is as $p \times Cp$, therefore the force wherewith p acts at d , in a direction perpendicular to CO , will be $p \times Cf$, and the force by which p endeavours to turn the body about O , will be as $p \times Cf \times do$; or $p \times Cf \times CO - Cd$, that is, as $p \times Cf \times EO - p \times Cp^2$. Now since the sum of all these forces to turn the body about O , must be $= 0$, therefore all the $p \times Cf \times Co - p \times Cp^2 = 0$, or all the $p \times Cf \times CO =$ all the $p \times Cp^2$. Therefore $CO =$ Sum of all $p \times Cp^2$.

Sum of all $p \times Cf$.
Therefore if s be equal the body, $Cp = x$, $Cf = v$, $dp = z$, then the sum of all the $Cp^2 \times p =$ sum of $x^2 s' =$ the fluent $x^2 s$; and the sum of $Cf \times p =$ the sum of $v s' =$ fluent of $v s$. And the sum of $dp^2 \times p =$ sum of $z^2 s' =$ fluent of $z^2 s$; therefore $CO = \frac{\text{Fluent of } x^2 s}{\text{Fluent of } v s} = \frac{\text{Fluent of } x^2 s}{Cd \times \text{body } AD}$
 $= Cd + \frac{\text{Fluent of } z^2 s}{Cd \times \text{body } AD}$. Therefore if we sup-

pose the body to be described or generated by a plane perpendicular, to the axis of the body, or parallel to the axis of motion we shall have the following.

Rule. First multiply the fluxion (or if the case require the second fluxion) of the body, by the square of the generating plane from the axis of motion, and find the fluent once or twice, as there is occasion by help of the equation of the figure, which call F . Secondly, Multiply the fluxion of the body by the distance of the point of suspension, to the point where the generating plane (or line, &c.) cuts the axis of the body, and find the fluent which call M ; and let d be equal the distance from the point of suspension to the center of gravity, and $B =$ the body, then $\frac{F}{M}$ or $\frac{F}{dB}$ will be the distance

tance of the center of percussio, oscillation, or center of preflure, &c. from the point of suspension.

We shall give a few examples, to shew the use of the above general rule in particular bodies, &c.

Example I. Let CB be a right line, (fig. 13.)

CB = x, then $\dot{F} = x^2 \dot{x}$, and $F = \frac{x^3}{3}$; also $\dot{M} =$

$x \dot{x}$, and $M = \frac{x^2}{2}$; whence $\frac{F}{M} = \frac{2}{3} x = CO$.

Example II. In a parallelogram, (fig. 14.) where the axis of motion is in the plane of the figure, CB = x, BD = b, then $\dot{F} = b x^2 \dot{x}$, and $F = \frac{b x^3}{3}$; also $\dot{M} = b x \dot{x}$, and $M = \frac{b x^2}{2}$; whence $\frac{F}{M} = \frac{2}{3} x = CO$.

Example III. Let AD be the arch of a circle, (fig. 15.) the center C the point of suspension, and the axis of motion perpendicular to its plane; let arch ABD = s, cord AD = c, CB = r. Then $F = r r s$; $d = \frac{r c}{s}$; therefore $\frac{F}{d B} = \frac{r s}{c}$.

Example IV. Let AD be a right line, (fig. 16.) the action of motion perpendicular to the plane passing through it. CB = d, BA = y, then $F = d d + y y \times 2 y$, and $F = 2 d d y + \frac{2}{3} y^3$; also $\dot{M} = 2 d y$; whence $\frac{F}{\dot{M}} = \frac{2 d d y + \frac{2}{3} y^3}{2 d y} = d + \frac{y y}{3 d}$.

Example V. For the periphery of a circle, (fig. 17.) let CD = d, radius AD = r, circumference = c. If the axis of motion be perpendicular to its plane, then $G = r r c$, and $d + \frac{G}{d B} = d + \frac{r r c}{d c} = d + \frac{r r}{d}$.

Example VI. For the periphery of the circle, (fig. 17.) parallel to ED, radius DB = r, BA = v, DL = z, CD = d, then $\dot{G} = 4 z x \dot{v} = \frac{4 r z z \dot{z}}{\sqrt{r r - z z}}$, and the whole fluent $G = \frac{r r c}{2}$; then

$d + \frac{d B}{G} = d + \frac{r r c}{2 d c} = d + \frac{r r}{2 d}$.

Example VII. In an isosceles triangle, (fig. 18.) where the axis of motion is parallel to the base, let

CD = a, CA = x, BE = f, then $IK = \frac{f x}{a}$, and

$\dot{F} = \frac{f x^2 \dot{x}}{a}$; whence $F = \frac{f x^3}{3 a}$; also $\dot{M} = \frac{f x^2 \dot{x}}{a}$, and

$M = \frac{f x^3}{3 a}$; therefore $\frac{F}{M} = \frac{2}{3} x = \frac{2}{3} a$.

If the axis at C be perpendicular to the plane of the triangle, let AQ = v, then $\dot{F} = x x + v v \times \dot{x} \dot{v}$, and $\dot{F} = x^2 \dot{x} + \frac{v^3 \dot{x}}{3}$ (because $v = \frac{f x}{a}$)

$\frac{f x^3 \dot{x}}{a} + \frac{f^3 x^3 \dot{x}}{a^3}$; whence $F = \frac{f x^4}{4 a} + \frac{f^3 x^4}{4 a^3} =$

$\frac{f a^3 + f^3 a}{4}$; therefore $\frac{F}{M} = \frac{2}{3} \times \frac{a a + f f}{a}$.

In the parabola, (fig. 19.) CAF, AC = x, AF = y, AQ = v, ax = y y; let the axis in C be parallel to AF, then $\dot{F} = y x^2 \dot{x} = x^2 \dot{x} \sqrt{a x}$, and $F = \frac{2}{7} x^3 \sqrt{a x}$; and $\dot{M} = y x \dot{x} = x \dot{x} \sqrt{a x}$, and $M = \frac{2}{5} x^2 \sqrt{a x}$. Therefore $\frac{F}{M} = \frac{5}{7} x$.

If the axis be perpendicular to its plane; then $\dot{F} = x x + v v \times \dot{x} \dot{v}$, and $\dot{F} = x^2 \dot{x} + \frac{v^3 \dot{x}}{3} = y x^2 \dot{x} + \frac{y^3 \dot{x}}{3} = x^2 \dot{x} \sqrt{a x} + \frac{a x \dot{x} \sqrt{a x}}{3}$; whence $F = \frac{2}{7} x^3 \sqrt{a x} + \frac{2}{15} a x^2 \sqrt{a x}$. Therefore $\frac{F}{M} = \frac{5}{7} x + \frac{1}{3} a$.

Example IX. Let AB be the surface of a sphere, (fig. 30.) AB = s, BE = z, radius AD = r, c = circumference. Then the circumference of BE = $\frac{c z}{r}$, and $\dot{G} = \frac{c z^2 \dot{z}}{r} = \frac{c z^2}{r} \times \frac{r \dot{z}}{\sqrt{r r - z z}}$;

whence $G = \frac{2 c r^3}{3} - \frac{2 c r z^2}{c} - \frac{c z z}{3} \sqrt{r r - z z} = \frac{2 c r^3}{3}$. And B = rc; therefore $d + \frac{G}{d B} = d + \frac{2 r r}{3 d}$.

Example X. Let ABQD be a parallelepipedon, (fig. 21.) the axis of motion perpendicular to the plane ABQD; let AB = 2 a, AD = 2 b. Breadth = c, GS = x, SZ = y; then $\dot{G} = x x + y y \times 4 c \dot{x} \dot{y}$, and $\dot{G} = 4 c x^2 \dot{y} + \frac{4 c y^3 \dot{x}}{3} = 4 c b x^2 \dot{x} + \frac{4}{3} c b^3 \dot{x}$. Therefore $G = \frac{4}{3} c b x^3 + \frac{4}{3} c b^3 x = \frac{4}{3} c b a^3 + \frac{4}{3} c b^3 a$; also B = 4 a c b. Therefore $d + \frac{G}{d B} = d + \frac{a a + b b}{3 d}$.

Example XI. In a cylinder, (fig. 22.) let CA = x, AD = r, Ae = y, CH = a, the axis of motion parallel to AB; then $\dot{F} = x x + y y \times 4 x \dot{y}$ $\sqrt{r r - y y}$ and the whole fluent $\dot{F} = \frac{r c x^2}{2} + \frac{r^3 c \dot{x}}{8}$. And $F = \frac{r c x^3}{6} + \frac{r^3 c x}{8}$; which corrected gives $F = \frac{r c x^3 - r c a^3}{6} + \frac{r^3 c x - r^3 c a}{8}$, and

$B = x - a \times \frac{r c}{4}$, then will $\frac{F}{d B} = \frac{2 x^2 - 2 a^2}{3 x^2 - 3 a a} + \frac{r r x - r r a}{2 x^2 - 2 a a} = \frac{4 x x + 4 a x + 4 a a + 3 r r}{6 x + 6 a}$.

Example XII. Let CKB be a pyramid, (fig. 23.) whose base is a parallelogram, and axis of motion in C perpendicular to the plane CEF; let its altitude = a, AB = f, AD = c, CH = x, HL = y,

$=y$, then $KI = \frac{cx}{a}$, and $EF = \frac{fx}{a}$, and $\bar{r} =$

$$\frac{cx^2 + yy}{a} \times \frac{cx^2 y}{a}; \text{ and } \bar{r} = \frac{cx^2 y}{a} y + \frac{y^2 x}{3a}$$

$$= \frac{cfx^2}{aa} + \frac{cf^3 x^4}{12a^3}. \text{ And } F = \frac{cfx^3}{5aa} + \frac{cf^3 x^5}{60a^3}$$

$$\text{Also } \bar{M} = \frac{cfx^3}{aa}, \text{ and } M = \frac{cfx^4}{4aa}; \text{ whence } \frac{F}{M} =$$

$$\frac{\frac{cfx^3}{aa}}{\frac{cfx^4}{4aa}} = \frac{12aa + ff}{15a}$$

Example XIII. In a right cone, (fig. 24.) let $CA = g$, altitude $= a$, radius of the base $= f$, $AB = x$, $BI = z$, $c = 3.1416$, then BE or $BD = \frac{fx}{a}$, $IE = \sqrt{\frac{ffxx}{aa} - z^2}$; then $\bar{r} = g + x^2$

$$+ z^2 \times 4x^2 \times \sqrt{\frac{ffxx}{aa} - z^2}, \text{ and } \bar{r} = g + x^2$$

$$\times \frac{cfx^2}{aa} + \frac{cf^3 x^4}{4a^3}, \text{ consequently } F = \frac{1}{3} ggc$$

$$x^3 + \frac{1}{2} gcx^4 + \frac{1}{2} cx^3 + \frac{cfx^4}{20aa} \times \frac{ff}{aa}; \text{ also } M$$

$$g + x \times \frac{cfx^2}{aa}, \text{ and } M = \frac{1}{3} ggcx + \frac{1}{2} cx^4 \times$$

$$\frac{ff}{aa}; \text{ whence } \frac{F}{M} = \frac{20gg + 30ga + 12aa + 3ff}{20g + 15a}$$

Example XIV. Let AD be a paraboloid, (fig. 25.) $CA = a$, $AB = x$, $BD = y$, $BI = z$, $c = 3.1416$, $rx = yy$. Then $\bar{r} = \frac{a + x^2}{2} + zz \times$

$$4x^2 \times \sqrt{\frac{yy}{a} - z^2}; \text{ therefore } \bar{r} = \frac{a + x^2}{2} \times cyy^2$$

$$+ \frac{cy^4}{4} \times a + x \times crx^2 + \frac{1}{2} cr^2 x^2 \bar{r}; \text{ whence}$$

$$F = \frac{1}{2} caarxx + \frac{1}{2} carx^2 + \frac{1}{2} crx^4 + \frac{1}{2} crr$$

$$x^2. \text{ Also } \bar{M} = \frac{a + x}{2} \times cy^2 \bar{r} = \frac{a}{2} \times crxx,$$

$$\text{and } M = \frac{1}{2} carx^2 + \frac{1}{2} crx^4. \text{ Therefore } \frac{F}{M} =$$

$$\frac{6a^2 + 8ax + rx + 3xx}{6a + 4x}$$

CENTER of a parallelogram, or Polygon, the point in which its diagonals intersect.

CENTER of pressure is that point against which a force being applied equal the sum of all the pressures, shall just sustain them, so as the plane shall incline to neither side.

This center of pressure is the same with the center of oscillation and percussion; and consequently is to be found in the same manner. See the rule under the article CENTER of Percussion.

CENTER of a Sphere, a point in the middle, from which all lines drawn to the surface are equal.

Hermes Trismegistus defines God an intellectual sphere, whose center is every where, and circumference no where.

CENTESIMATION, a milder kind of military

punishment, in cases of desertion, mutiny, and the like, when only every hundredth man is executed.

CENTIPES, in zoology, the same with the scolopendra. See SCOLOPENDRA.

CENTNER, among metallurgists and assayers, denotes a weight divisible first in an hundred, and afterwards into other lesser parts. However, it is to be observed, that the centner of metallurgists is the same with the common hundred weight; whereas that of assayers is no more than one dram, to which the other parts are proportional, and nevertheless pass by the names 100 lb. 64 lb.

CENTO, in poetry, a work wholly composed of verses or passages, promiscuously taken from other authors, only disposed in a new form and order.

Proba Falconia has written the life of Jesus Christ in centos, taken from Virgil: Alexander Ross has done the like in his Christiados, and Stephen de Pleure the same.

Ausonius has laid down rules to be observed in composing centos: the piece, says he, may be taken from the same poet, or from several; and the verses may be either taken entire, or divided into two; one half to be connected with another half taken elsewhere: but two verses are never to be used together, nor much less than half a verse taken.

CENTRAL, something belonging or relating to center. See the article CENTER.

CENTRAL Forces, the power which causes a moving body to tend towards, or recede from the center of motion.

A body in motion continues its motion in a right line, and will not deviate from it, unless it be acted upon by a new impulse; after the impulse the motion is compounded, and out of these two, there arises a third still in a right line. If therefore a body moves in a curve, it is acted upon every moment by a new impulse; for a curve cannot consist of straight lines, unless such as are infinitely small. We have one example of such a motion in the projection of heavy bodies; and another in all motions about a point taken as a center.

A body that is continually impelled towards some center, when projected in the direction of a right line, not passing through that center, will describe a curve; and in all points thereof endeavours to recede from the curve, in the direction of its curvature; that is, in a tangent to the curve; so that if that force should suddenly cease from action, the body would continue its motion in a right line along that tangent.

A stone turned, run in a sling, describes a curve; the sling does, as it were, every moment draw the stone back towards the hand; but if you let the stone go, it will fly out in a tangent to the curve. Therefore,

The force with which a body, in the case above-mentioned, endeavours to fly from the center, such as is the force, by which the string in motion is stretched, is called a centrifugal force.

But the force, by which a body is drawn, or impelled towards that center, is called a centripetal force.

These forces, by a common name, are called central forces.

In every case, the centrifugal and centripetal forces are equal to one another: for the former is the resistance of the body, while it is drawn by the centripetal force. Here it may be applied whatever has been said of a resistance from inactivity.

A body is kept in a curve by a centripetal force, and endeavours to fly from it by a centrifugal force. The sling in motion is equally stretched both ways, and the stone endeavours to fly from the hand, with the same force that the hand holds it; that is, it is drawn towards the hand.

Central forces are of great use in natural philosophy; for all the planets move in orbits, and most of them, if not all, revolve about their axes.

When a body laid upon a plane, does in the same time and above the same center revolve with that plane, and so describes a circle; if the centripetal force, by which the body is drawn or impelled every moment towards that center, should cease to act, and the plane should continue to move with the same velocity; the body will begin to recede from the center, in respect of the plane, in a line which passes through the center. The body indeed endeavours to fly off in a tangent; but the point of the circle to which it answers, is moved with the body and the motion along the tangent of the circle at rest, in the first moment, is agitated by the radius of the circle moved with the same velocity as the body.

When a body projected is acted upon by a force tending to some center, it moves in that plane which passes through the direction of the projection, and the center of the forces.

When a body moves about a center, if in its motion it comes nearer to the center, its motion is accelerated; but on the contrary retarded, if it recedes from the center.

This acceleration and retardation is subject to the following law.

A body that is retained in a curve by a force, tending towards a center, describes areas about that center proportional to the times.

Let there be a given body describing the curve A B D E, (Plate XXXI. fig. 26.) in which it is retained by a central force tending to C; if lines be drawn at pleasure, as A C, B C, D C, E C, the area of the mixed line triangle A C B will be to the area D C E, as the time in which the body moves through A B is to the time in which the body moves through D E.

The proposition being the inverse of this, is also true, viz. That a body which is moved in any curve in a plane, and describes areas about some point proportional to the times, it is turned out of the right line, and urged by a force tending to that point.

We shall now shew how to compare central forces with one another; for which purpose we are to consider a centripetal force, as a pressure acting upon a body. Because the body is turned out of a straight line in every point, the deflection of a right line every moment is the immediate effect of a pressure; so that what has been demonstrated of the actions of powers upon obstacles left to themselves, may be applied here.

The greater the quantity of matter in any body is, the greater is its centrifugal force, all things else being alike; since the inactivity being greater, it is drawn towards the center with more difficulty.

If fluids of equal quantities, but unequal weights, be included in a determinate space, so that the heavier cannot recede from the center, unless the lighter comes towards it, and they be so disposed, that by their weight the heavier comes to the center; upon moving the whole about that center, the lighter fluid will be carried towards the center, and the heavier ones will fly from it.

If a solid with a fluid be included in a determinate space; if it be lighter than the fluid, it will come to the center; if heavier, it will recede from that center: all of which proceeds from the heavy bodies having the greater centrifugal force.

Central forces do not only differ with respect to the quantity of matter, but the distance from the center does also cause an alteration; and likewise the velocity with which the body moves about: there is nothing else can make a difference in these forces: and these are all the things to be considered when we compare them together.

When the periodical times are equal, and the distances from the center are equal, the central forces are to one another, as the quantities of matter in the revolving bodies.

When the quantities of matter in the revolving bodies are equal, and the periodical times are equal, the central forces are as their distances from the center.

When the periodical times are equal, but the distances from the center, and the quantities of matter in the revolving bodies are different, the central forces are in the ratio, compounded of the quantities of the matter, and of the distances; which follows from the two last propositions. And to determine this compound ratio, the quantity of matter in each body, must be multiplied by its distance from the center, and the products will have the ratio required.

The differences of central forces, arising from the different distances from the center and the quantities of matter, may have a mutual compensation;

and

and supposing the quantities of matter in the revolving bodies, to be in the inverse ratio of the distances from the center, the central forces will be equal; as much as one force is greater than another, with respect to the quantity of matter, so much does this exceed that, because of the greater distance.

This case of the proposition takes place, when two bodies joined by a thread revolve about the common center of gravity; for the distances from this center are in the inverse ratio of the weights of the bodies, and therefore the central forces are equal. One body is drawn to the center with the same force that the other endeavours to recede from it; and because of the equality of the forces, they mutually keep up each other, and continue the motion. If they revolve about some other point, they will not continue in motion; and that body, whose centrifugal force prevails, will recede from the center, and the one body will carry the other along with it.

The difference of central forces, may also be determined from the periodical time.

When the quantities of matter of the bodies moved round, and the distances from the centers are equal, the central forces are in an inverse ratio of the squares of the periodical times; that is, directly as the squares of the revolutions performed in the same time.

However the central forces differ from one another, they may from what has been already said, be compared to one another; for they are in the ratio compounded of the quantities of matter in the revolving bodies, and the ratio of the distances from the center, as likewise in the inverse ratio of the squares of the periodical times. If you multiply the quantity of matter in each body, by its distance from the center, and divide the product by the square of the periodical time, the quotient of the division will be to one another in the said compounded ratio; that is, as the central forces.

When the quantities of matter are equal, the distances themselves must be divided by the squares of the periodical times, to determine the proportion between the central forces.

In that case, if the squares of the periodical times be to one another as the cubes of the distances, the quotients of the division will be the inverse ratio of the squares of the distances; and in this ratio are also the central forces.

When the bodies be unequal, and central forces of the same nature with gravity act upon them, it matters not what the masses of the bodies be, or how they move; they are drawn towards the center in equal moments, spaces which are proportional to those forces, and the last proportion takes place even in unequal bodies.

A body may describe several sorts of curves by a central force.

Geometricians call an ellipsis an oval line, whose generation is this; let Aa (Plate XXXI. fig. 27.) be a right line; C the middle point thereof; F, f points equally distant from C ; FGf a thread whose ends are fastened in F, f , and length equal to the line Aa . Then if the thread be stretched, an ellipsis may be described in the same plane wherein is Aa , by the motion of a pin G .

If a cone or a cylinder be cut by a plane, the section will often be such a line. The points F, f , are called the foci, C the center, Aa the greater axis, and Bb passing through the center, perpendicular to Aa , and terminated both ways by the curve, is the lesser axis.

Let us suppose the force, mentioned in the last proportion, acting upon bodies in motion, just as upon those at rest, which is equal at equal distances from the center, but at different distances is inversely as the square of the distance; the body by this force would move in an ellipsis, one of whose foci coincides with the center of the forces; so that a body may describe a curve running into itself, and in every revolution will once come towards the center of forces, and once go farther from it. In the recess the velocity of the body is lessened, and indeed so, that the central force, although that be lessened itself, it bends in the path of the body, and makes its endeavour to come towards the center. In the access the velocity will be so augmented, that although the force be augmented, the body again recedes from the center.

A circle belongs to these kind of curves, when the foci coincide with the centre. And supposing a body, as we here said, to describe an ellipsis, another body will be retained by the same force about that center, if this be projected with a just velocity perpendicularly to the line passing through the center. If the diameter of the circle be equal to the greater axis of the ellipsis, the body will be urged with that velocity, whereby the body moves in an ellipsis in that moment, as it passes through either of the ends of the lesser axis; and both these bodies will make their revolutions in equal times.

A body may be projected with such velocity, that the force in the recess from the center, which upon the augmentation of the distance is lessened, is not sufficient to bend in the body's path, so that it may return again: in this case the body will describe another of the conical sections, either a parabola or hyperbola.

If the central force as you go from the center decreases in any other proportion, the body will not describe a line returning into itself, and somewhat differing from a circle.

But if the force decreases in a proportion a little different from that, the curve described by the body may be taken as a moveable ellipsis, whose axis will move with an angular motion in the plane in which

Fig. 3.
Central Machine.

Fig. 14.

Fig. 13.

the body revolves, the focus remaining in the center of the forces. But the motion of the axis tends the same way with the motion of the body, if the force decreases swifter upon augmenting the distance, than in the inverse ratio of the square of the distance.

But if the force be slower; that is, decreases less as you go on from the center, the motion of the ellipsis will be the contrary way.

A body will also describe an ellipsis, if the central force, as you go from the center, increases and is every where in the ratio of the distance from the center, which in that case coincides with the center of the ellipsis.

If also a force increases in any other ratio, the curve will not return into itself, but may often be referred to an ellipsis, moveable in a plane about a center: whence it follows, that an excentrical curve returning into itself, can be described by no central force; that is, one whose center does not coincide with the center of the forces, and a small matter differing from a curve, except an ellipsis, in one of whose foci the center of the forces is, and that the central force in this case is inversely as the square of the distance.

But it easily appears that a circle whose center coincides with the center of the forces, may be described by a force increasing or decreasing in any given ratio; supposing it to act equally at equal distances.

CENTRAL-RULE, is a rule, or method discovered by our countryman, Thomas Baker, whereby we are enabled to find the center of a circle designed to cut the parabola, in as many points as an equation to be constructed hath real roots. Its principal use is in the construction of equations, which he has applied with good success as far as biquadratics.

The central-rule is chiefly founded on this property of the parabola: that if a line be inscribed in that curve perpendicular to any diameter, a rectangle, formed of the inscript, is equal to a rectangle made of the intercepted diameter and parameter of the axis.

The central-rule has the advantage over Carter's, and De Lattres's method of constructing equations, in that both these latter are subject to the trouble of preparing the equation by taking away the second term. This we are freed from in Baker's method, which shews us how to construct all equations not exceeding the fourth power, by the intersection of a circle and parabola, without the omission or change of any terms.

CENTRAL MACHINE, a machine invented to show the laws of the central forces experimentally, of which take the following description, as given by Dr. Defaguliers.

(Plate XXXII. *fig. 1.*) The machine for central forces consists of a strong wooden frame

CABDHGKEF triangular at top and bottom. On the horizontal piece *Ga* at top is a wheel *G*, which (by means of the string *GKHG*) when turned round, gives circular motion to the pulleys and spindles *KL* and *HI*, so as to move them either with equal velocities, or with velocities that are as 2 to 1, as 3 to 1, or as 3 to 2; because in the pulley *K* there are two grooves, one of 3, and one of 2 inches diameter; and in the pulley *H* there are also two, one of 6, and one of 3 inches diameter. There are two pieces *MN*, *mn* (which we may call planet-bearing pieces) of about 30 inches long, to be screwed upon the pulleys *K*, *H*, so as to turn round with them. These pieces have each of them an open square tower *S*, *s*, with a little pulley at top and bottom to conduct a string from the weights *S* and *s*, to the brass balls *P* and *p*, (which we must here call planets) so that when *P* and *p* go towards *N* or *n*, the weights are drawn up from their bases, which is about an inch above the bottom of the towers, and rise within the towers till the weight-carrying piece strikes the top of the tower; each ball having two little wings with holes in them to slide easily along little wires that go from one end to the other of the planet-carrying piece, passing through the two perpendicular brass planes *M* and *N*, also through the towers at about the distance of one fourth of an inch from the surface of the planet-carrying piece. *N. B.* Only one of the wings and one of the wires is here drawn upon each piece to avoid confusion. There are also brass collars at *H* and *K*, in which the necks of the spindles (which are of steel) turn; and iron screws headed with brass at *L* and *I*, with little holes to receive the bottoms of the spindles.

The second figure represents something more than half of one of the planet-bearing pieces divided into inches both ways from the center. *Bb* is the perpendicular brass plane at one end, through which the horizontal wires *Ww*, *Ww* pass, to carry the planet *P* by its perforated wings *LL*, whilst the string that goes through the middle of the planet is made fast, by thrusting in the little pin *p* to give the planet any certain distance from *T* the center of its motion before it is moved round by turning the wheel *G* (in *fig. 1.*) *Ss* represents the section of the brass tower fastened to the wood by a cross pin, whose head is seen at *s*. *T* is the base or plate which is to support the weight-carrying piece, which is represented at (*fig. 4.*) and consists of a circular plate and hollow stem of two ounces weight, and on which may be slipped several leaden weights like *X* (*fig. 5.*) At *T* also (*fig. 2.*) may be seen the little pulley under which the string goes.

The 3d figure is a vertical section of one of the square towers *Ss*, with the weight *X*, and weight-carrying piece *Xx* in it, and part of the planet-bearing piece, pulley and spindle under it, marked *MN*. One little pulley is fastened to the wood at

T under the plate on which the weights stand; another is sustained by an iron arm V S over an hole S in the top of the tower. So that the string coming from the planet P goes first under the pulley T, then through the hollow stem of the weight-carrying piece, and so through the hole in the top of the tower, then over the pulley S, so down again to the top of the stem of X, where it is fastened. By observing this figure, one may easily see that if the planet P be moved ever so little in the direction of I Q, the weight-bearing piece X will be raised up towards S.

The whirling table which we have already mentioned for making several experiments, is best turned round by screwing on to the top of either of the spindles L K or I H, instead of the planet-bearing piece M N or *mn*.

The sixth figure represents the section of the wheel and part of the horizontal piece, the upper part of the frame which carries the wheel, and the upper end of the piece that supports it marked L L L, the wheel's axis and square-sliding collar *g*, which is moveable on the square horizontal iron H I fastened to the wood by a nut and pin at I, and two wood-screws H *h*. N. B. There is a screw in the sliding piece *g* to fix the center of the wheel, when it is brought forwards or backwards.

Tho' it be of no consequence of what bigness the machine above described is made, provided its parts are proportional; yet for the sake of those who would have such a machine made, I give here the measures of the principal parts of mine in English inches.

(Plate XXXII. fig. 1.) The thickness of the wood every where about 1 inch, except the feet at A and D, where it is 2 inches thick.

MN = *mn* = 30 inches.

KH 33 $\frac{1}{2}$ inches.

KL = IH = 8 $\frac{1}{2}$ inches.

AD = 34 $\frac{1}{2}$ inches.

AC = CD = 27 $\frac{1}{2}$ inches.

BC = 24 $\frac{1}{2}$ inches.

Diameter of the groove of the wheel G = 14 $\frac{1}{2}$ inches.

Breadth of the planet-bearing piece M N or *mn* = 2 $\frac{1}{2}$ inches.

Grooves of the pulley K, the one 2 and the other inches.

Grooves of H, the one 6 and the other 3 inches.

The height AK = HD = 13 inches.

Height of the towers S or *s* above the board MN, *mn* 5 $\frac{1}{2}$ inches.

Breadth of the towers = 23 inches.

There are 4 brass planets made use of, two of which weigh each 2 ounces Troy, and the two other 4 ounces Troy each.

The weight-carrying plate and stem weighs 2 ounces, and each leaden weight (as represented by fig. 5.) weighs 2 ounces also.

What is to be considered in the use of the machine.

9. The weights in each tower are to represent the sun, whose attraction is shewn by the force with which the weight resists the action of the ball P or *p*, (representing a planet) that endeavours to raise it by the string P T S *x* (fig. 3.) when it receives a centrifugal force by turning the wheel G. So that by putting equal or unequal weights in the towers; by using equal or unequal planets, as P, or *p*; and by having their distances equal or unequal in different proportions; and the periodical times equal or unequal (as the wheel-string goes round equal or unequal pulleys) we may by experiments shew those laws of central forces, which Sir Isaac Newton has mathematically demonstrated in his Principia.

In considering the central forces of bodies (for example, of the primary planets in respect of the sun, and of the moons in respect to their primary planets) which move round other bodies that have an influence upon them; we are to observe three things. 1st, The periodical time, or times in which the bodies perform their revolutions. 2^{dy}, The quantity of matter in the revolving bodies. 3^{dy}, The distance of the bodies from the center of the revolution.

Exper. I. First, make the periodical times equal, by putting the wheel string into the 2 inch groove of each pulley, crossing it before each pulley to give it the more force to move the pulleys, but so that the pulleys may both turn the same way that the planet-bearing pieces may not uncrow. Then put only the weight-carrying piece into each tower: and lastly, fasten to their strings a 2 ounce brass ball, as P and *p*, at the distance of 12 inches from the center on each planet-bearing piece. So you will have the periodical times, the quantities of matter, and distances from the center equal. Give circular motion to the wheel G, and the planets by their centrifugal force will raise the planets S and *s* at the very same instant of time; which shews, that in this case the centrifugal forces are equal. N. B. If upon each weight-carrying piece you put on one or two, or more equal weights (such as are expressed by fig. 5.) the planets will always raise them at the same instant, provided the wheel be turned proportionally faster as there is more weight.

Exper. II. Secondly, Instead of *p* put on a 4 ounce ball, and double the weight in the weight *q*; then turn the wheel, and both weights will rise at once. This shews, that when the quantities of matter are unequal, but the distances and periodical times still remain equal, the centrifugal force is proportional to the quantity of matter.

Exper. III. Thirdly, take off the 4 ounce ball, and make use of *p* again, but put it only at 6 inches from the center. Take the additional weight from *s* and add it to S; that is, let the weight S, which has P at 12 inches distance, be = 4 ounces; and the weight *s*, which has *p* but at 6 inches distance, be

= 2 ounces:

= 2 ounces: then upon turning the wheel, they will both rise at the same time. Hence it is plain, that if the periodical times, and the quantities of matter continue the same, but the distances are different, the centrifugal forces will be as the distances.

Exper. IV. Fourthly, at the distance of 6 inches, where p was last, change p for a 4 ounce ball, and put equal weights in the two towers; then when you turn the wheel, both weights will rise at once; which shews, that when the periodical times are equal, and the distances from the center reciprocally as the quantities of matter in the planets, the centrifugal forces are equal.

Exper. V. Lastly, Change the string on the pulley H, putting it into the groove of 6 inches diameter, so that the periodical time of the planet P, which last will then move twice as fast, if its distance be the same from the center, which it must be in this experiment. Put 8 ounces in the tower SQ, and only 2 in the tower sq, the equal planets P and p being then each at 12 inches distance from the center. Turn the wheel, and both weights will rise at once. This shews, that planets, that have an equal quantity of matter and the same distance from the center, but different periodical times, have their centrifugal forces reciprocally as the square of their periodical times; that is, directly as the square of their velocities.

Coroll. Hence follows, that if the same planet changes in velocity in the same orbit, its centrifugal force will increase or decrease according to the square of the velocity which the planet has in that orbit.

Scholium. When we compare the last experiment with the 3d experiment, and find that the planet (p going round in a circle of 12 inches radius at the same time that P went round in a circle of 6 inches radius,) raised twice the weight because it had twice the velocity; it will appear strange, that in the last experiment, where p (going twice through a circle of 12 inches radius, whilst P goes once through such a circle) has but double the velocity of P, it should now raise four times more weight. But this proportion (which is of very great use in explaining the motions of the heavenly bodies) will be very clearly deduced from a consideration of the first law and what we have said upon it.

CENTRIFUGAL FORCE, is that whereby a body revolving round a center, endeavours to recede from it.

Dr. Desaguliers, in his Experimental Philosophy, gives various experiments, to shew and illustrate the nature of centrifugal and centripetal forces, from which author the following experiments are collected.

Exper. I. (Plate XXXII. fig. 7.) ABCD is a round table which may be swiftly turned upon a pivot, as at F (the same that is represented by the first figure on this plate.) There is a little brass pipe screw'd in at the center C, into the top of

which the firing of the leaden bullet B is thrust so as to go out at an hole in the side of the said short brass pipe; thence it is carried under the table thro' the hole b , and so fasten'd to a pin in the side of the table at A. When the bullet is laid at B, if the table be turn'd swiftly round, it leaves the bullet behind at first, which thereby appears to have a motion contrary to that of the table, till by the roughness of the surface of the table, it goes round at last along with the table on the same part of the table; then if the table be stopp'd on the sudden, the bullet goes on several turns, till having communicated all its motion to the rough surface of the table, it comes to rest at last. This illustrates the first law of nature; for as the part of the table under the bullet leaves it behind for a while, because it endeavours to continue in its state of rest, it would for ever leave it where it was at first, if the table was perfectly smooth: and when the bullet is once in motion it would for ever go round on the table, if (besides the smoothness of the table) the string that holds the ball had no friction at the center C. It is also to be observed, that the string, which is slack at CB, is always stretched as at Cb by the motion of the bullet; and this shews the centrifugal force.

If we screw a forked prop toward the edge of the table as at D, and put the string of the bullet into its slit so as to let the bullet hang down as at 1, the force of the bullet's gravity may be so overcome by the centrifugal force, which the whirling of the table produces, that the bullet shall rise to 3, the string 3d becoming horizontal: as the table turns slower and slower, the ball comes down to 2 and so to 1 at last, gravity becoming sensible as the centrifugal force diminishes.

Exper. II. (Plate XXXII. fig. 8.) If a string be tied round the brim of a pot full of water, and the pot be whirled round swiftly about the hand or center K in a circle or curve of which ACB is an arc, the water acquiring a centrifugal force greater than that of gravity, will not be spilled when the mouth of the pot is downwards. If instead of the pot, the glass WC (fig. 9.) containing liquors of different specific gravities be whirled round the center K, (after they have been confounded together by shaking) they will all recover their places and transparency, even sooner than if the glass containing them had been hung up and at rest. The reason is, that as the different substances in the glass have the same velocity given them by the centrifugal force, their momentum will be as their specific gravities, that is, their momentum will be made up of the different quantities of matter, which they contain under equal bulks multiplied by the common velocity which the centrifugal force gives them in the line K/C from the center of the motion towards the circumference. Therefore the glass beads among the liquors weighing more than the
drops.

drops of any of the liquors, will have the greatest momentum, and consequently go to the part G most remote from the center of motion K. Then the drops of oil of tartar (which is the heaviest of the liquors contained in the glass) having for the same reason more momentum than the drops of the other liquors (tho' less than the glass beads) will take up the space T next to the beads, and also fill their interstices. The next liquor which is oil of Peter, will fill up the space P. And lastly, the spirit of wine, whose drops are the lightest, will (notwithstanding its own centrifugal force) be brought nearer to the center of motion, and occupy the space W; because the beads and all the other liquors having more momentum, drive it from the end C, to which it has a tendency all the while. N. B. The tube is hermetically sealed at both ends.

The glass beads, and different liquors, settle in their proper places when the tube is hung up; because, as all bodies tend downwards with the same velocity, the momentum of particles of equal bulk must be as their respective quantities of matter in their descent: and that the liquors will not be so soon settled in this case as when the tube is whirled round, is because we can give as great a velocity as we please in the direction KC, by a centrifugal force; whereas that which is owing to gravity is always the same.

Coroll. Hence it follows, that a bottle of any liquor (which after having been muddy is by length of time become fine, and is again made foul by shaking) may sooner be brought to be fine by a centrifugal force, than by being set upright at rest.

Exper. III. (Plate XXXII. fig. 10.) Join, by a string, the two balls T. and M. whose weights are to one another as 4 to 2 (here we use a two-ounce to a four-ounce ball) and pass the string through the opposite side-holes of the little pipe C; let the length of the string, measuring from center to center of the balls, be 18 inches, and the distances of the centers of the balls from the table be reciprocally as their masses; that is, the center of the two-ounce ball M must be at the distance of 12 inches from C, and the center of the four-ounce ball T at 6 inches from C. Let the two little squares, or rectangular pieces S and V be fixed on the table at the distance of about 1 inch or 2 behind the balls to stop them from flying off of the table, and the long sides of those pieces to fixed alternately, that when the table is made to turn in the direction marked by the dart, the balls may not be left behind, but immediately put into motion. Now let the table be whirled round with any velocity, and the balls will remain at the points T and M, and describe round their common center of gravity unequal circles in a reciprocal proportion of the masses, the momenta given the bodies by the centrifugal force being equal, and (because of their contrary directions) destroying another. But if ei-

ther of the balls be removed farther from C than in the reciprocal proportion above-mentioned, that ball will gradually recede from the center of motion, and draw the other along with it, till it be stopped by the end of the piece V or S. So the earth and moon turn round one another, and round their common center of gravity, as has been already observed.

Exper. IV. (Plate XXXII. fig. 11.) On a piece of board A E K, which has a piece under it across to raise up its broadest end A E to the angle of 15 or 20 degrees above the horizontal position, are fastened 3 tubes A K, C K and E K, shut up at both ends. In the first there is a small cylinder of cork, which can easily slide up and down the tube: in the tube C K there is a little cylinder of lead moveable in the same manner: and in the tube E K, there is an inch or two of quicksilver shut up. This board has a screw under it, which going through one of the holes of the table (such as are marked A and B in Plate XXXII. fig. 7.) is fastened by a nut so as to join the board of tubes firmly to the table. Then when the cork, lead, and quicksilver are in that part of the tube next to the center of motion K; let the table be whirled round, and those bodies will after a few turns be carried to the ends of the tubes which are farthest from the center, though 3 or 4 inches higher than the ends at K. Put on the tubes B K and D K, the first of which being filled with water has a cork cylinder moveable in it; and the other has in it an inch or two of oil, the other part of it being full of water. At first (when the table is at rest) the cork and the oil will be at B and D the higher ends of the tubes and farthest from the center; but when the table is whirled round, the cork and the oil will go towards the center to K, because the greater centrifugal force of the water (being greater than either that of the cork, or that of the oil) must give the cork and the oil a centripetal direction, as has been explained in the experiment of the different liquors in the glass of fig. 9.

CENTRIFUGAL MACHINE, a very curious machine, invented by Mr. Erskine, for raising water by means of a centrifugal force, combined with the pressure of the atmosphere.

It consists of a large tube of copper, &c. in the form of a cross, which is placed perpendicular in the water, and rests at the bottom on a pivot. At the upper part of the tube is a horizontal cog-wheel, which touches the cogs of another in a vertical position; so that by the help of a double winch, the whole machine is moved round with great velocity.

Near the bottom of the perpendicular part of the tube is a valve opening upwards; and near the two extremities, but on contrary sides of the arms, or cross part of the tube, are two other valves opening outwards. These two valves are, by the assistance

of springs, kept shut till the machine is put in motion, when the centrifugal velocity of the water forces them open, and discharges itself into a cistern or reservoir placed there for that purpose.

On the upper part of the arms are two holes, which are closed by pieces screwing into the metal of the tube. Before the machine can work, these holes must be opened, and water poured in through them, till the whole tube be full: by this means all the air will be forced out of the machine, and the water supported in the tube by means of the valve at the bottom.

The tube being thus filled with water, and the holes closed by their screw caps, it is turned round by means of the winch, whence the water in the arms of the tube acquires a centrifugal force, opens the valves near the extremities of the arms, and flies out with a velocity nearly equal to that of the extremities of the said arms.

The above description will be very easily understood by the figure we have added on plate XXXII. fig. 12. which is a perspective view of the centrifugal machine, erected on board a ship.

A B C is the copper tube.

D, a horizontal cog-wheel, furnished with twelve cogs.

E, a vertical cog-wheel, furnished with thirty-six cogs.

F, F, the double winch.

a the valve near the bottom of the tube.

d, b, the two pivots on which the machine turns.

e, one of the valves in the cross piece; the other at d, cannot be seen in this figure, being on the other side of the tube.

e, e, the two holes through which the water is poured into the machine.

G H, the cistern, or reservoir.

I, I, part of the ship's deck.

The distance between the two valves e, d, is six feet. The diameter of these valves is about three inches; and that of the perpendicular tube about seven inches.

If we suppose the men who work the machine can turn the winch round in three seconds, the machine will move round its axis in one second; and consequently each extremity of the arms will move with a velocity of 88.8 feet in a second. Therefore a column of water of three inches diameter will issue through each of the valves with a velocity of 18.8 feet in a second: but the area of the aperture of each of the valves is 7.14 inches²; which being multiplied by the velocity in inches = 225.6, gives 1610.784, cubic inches, the quantity of water discharged through one of the apertures in one second; so that the whole quantity discharged in that space of time through both the apertures is = 3221.568 inches³; or 193294.08 cubic inches in one minute. But 60812 cubic inches make a tun, beer measure; consequently, if we suppose

the centrifugal machine revolves round its axis in one second, it will raise nearly three tuns forty-four gallons in one minute; but this velocity is certainly too great, at least to be held for any considerable time; so that when this and other deficiencies in the machine are allowed for, two tuns in a minute is nearly the quantity that can be raised by it in one minute. And that this computation is near the truth appears from an experiment made on the 14th of May last, on board the Princess Mary at Woolwich, when the centrifugal machine was found to exceed the chain pump, at the rate of nineteen tuns and a half per hour; both being worked by an equal number of men. Now a good chain-pump will extract something more than a ton and a half in a minute, or about ninety tons in an hour.

It will perhaps be unnecessary to observe, that as the water is forced up the perpendicular tube by the pressure of the atmosphere, this machine cannot raise water above thirty feet high.

CENTRIPETAL FORCE is that force by which any body moving round another is drawn down or impelled towards the center of its orbit; and is much the same with gravity, whereby bodies tend towards the center of the earth; the magnetical attraction whereby it draws iron; and that force, whatever it be, whereby the planets are continually drawn back from right lined motions, and made to move in curves.

The centripetal and centrifugal force of the same revolving body, in the same point of the curve it describes, are always equal and contrary.

To determine what the law of centripetal force must be, is a problem of the greatest importance, and may be solved either by lineal, geometry; or by fluxions. In the first method it has been often done; but it is much more general and expeditious by the latter; therefore we shall give a general rule for determining the law of the centrifugal force.

Let B (Plate XXXIII. fig. 1.) be the place of the body moving in the orbit B F by a force directed to the given point C. Draw the tangent B Y, and the radius C B, C Q, infinitely near each other, Q R parallel to C B, and C Y, Q N perpendiculars to B Y. Let the distance C B = D, perpendicular C Y = P, then the infinitely small line Q R will be as the force and square of the time conjunctly, that is as the force and square of the area C B Q; therefore the

force is as $\frac{Q R}{C B \times Q}$ or $\frac{Q R}{C B \times P \times \frac{Q R}{P}}$, that is

(because $P : D :: Q N : Q R = \frac{Q N \times D}{P}$) as $\frac{Q N \times D}{Q P^2 \times P}$. But $\frac{Q B^3}{2 Q N} = \text{radius of curvature in}$

the point B, and the same radius is also $\frac{D \dot{D}}{P \ddot{D}}$,

wherefore the force is as $\frac{P}{2 P_3 D}$ that is supposing

$\dot{D}$ to be given) by the fluxion of $\frac{-1}{r P}$.

Therefore to find the law of centripetal force, let D = distance from the center of force, P = perpendicular on the tangent: compute the value of P in terms of D , by the nature of the curve; then find the fluxion of $\frac{-1}{r P}$, making $\dot{D} = 1$, and then expunge all the quantities as far as possible, except D , and you will have F , the law of centripetal force required. See the articles CENTRAL FORCES and CENTRIFUGAL FORCE.

CENTRO-BARYC, in mechanics, is the method of determining the content of a superficies or solid, by means of the center of gravity.

This method was first taken notice of by Pappus; but after him the jesuit Guildinus set this method in its full light, and shewed its use in a variety of examples.

Since Pappus and Guildinus, several other geometers have also used it in measuring solids, generated by a rotation round a fixed axis; especially before the method of fluxions was invented, which has in a great measure rendered this centro-baryc method of little use. However, the two following theorems, with the demonstrations and the corollaries, being part of a paper in the Mathematical Transactions, delivered in by Mr. Samuel Clark, may not be unacceptable to some of our readers.

Theor. I. Let G (Plate XXXII. fig. 13.) be the center of gravity of the space ABC , contained by the right-lines AB , BC , comprehending a right-angle, and the curve-line ADC of any kind whatsoever: From G , draw GX parallel to BC . Now if we conceive the said space to be divided into an infinite number of equal parts, by the lines FD , FD , FD , &c. drawn parallel to BC , then will the sum of the segments AFD , AFD , &c. be equal to the whole figure $ABCD$, multiplied by XB .

Demonstration. Put n for the number of equal parts into which AB is divided, at the points FFF , &c. z the sum of the ordinates FD , FD , FD , &c. or area of the whole space, and let the parts AFD , FD , FD , &c. wherein the small letters a , b , c , d , e , &c. are placed, be represented by those letters; then BX the distance of the center of gravity, from the point of suspension B , will, by the principles of mechanics, be expressed by

$$\frac{n a + n-1 \times b + n-2 \times c + n-3 \times d, \&c. \dots n}{z}; \text{ but}$$

$$a + b + c + d, \&c. \dots n = ABC$$

$$a + b + c + d, \&c. \dots n-1 = AFD$$

$$a + b + c + d, \&c. \dots n-2 = AFD$$

Whence the sum of the infinite number of segments equal to $n a + n-1 \times b + n-2 \times c +$

$n-3 \times d, \&c.$ continued until the number of terms is n , and is evidently equal to the above value of BX multiplied by Z . *Q. E. D.*

Theorem II. Things remaining as before, let the space ABC be made to revolve about the ordinate BC as an axis, by which a solid will be formed, whose content will be equal to the area of the said space, multiplied by the circumference of that circle, which the center of gravity G describes during one entire revolution of ABC about the axis BC .

Demonstration. The solid formed by the circumvolution of ABC about the axis BC , may be considered as made up of the upright surfaces of an infinite number of cylinders, whose perpendicular heights are the ordinates FD , FD , FD , &c. this being premised, let r to r express the ratio of the diameter to the circumference of a circle, then will the sum of such upright surfaces be equal to $2 n a r + n-1 \times 2 b r + n-2 \times 2 c r + n-3 \times 2 d r, \&c. \dots n$. But BX , the distance of the center of gravity from the ordinate BC , is equal to $\frac{n a + n-1 \times b + n-2 \times c, \&c. \dots n}{z}$; which

being multiplied by $2 r$, gives the periphery of the circle described by the center of gravity; this again multiplied by z , the area of ABC , produces

$$2 n a r + n-1 \times 2 b r + n-2 \times 2 c r + n-3 \times 2 d r, \&c.$$

z
 $\times z$, which is certainly equal to $2 n a r + n-1 \times 2 b r + n-2 \times 2 c r + n-3 \times 2 d r, \&c.$ the content of the solid formed by the revolution of ACB about the axis BC . *Q. E. D.*

From these theorems the following corollaries are deduced.

Corollary I. The area of the space ABC , multiplied by GX , the distance of the center of gravity from $A B$, is equal to the sum of all the segments made by dividing ABC into an infinite number of equal parts, by right-lines drawn parallel to $A B$.

Cor. II. If the figure ABC revolves about the abscissa AB as an axis, the solid so formed will be equal to the area of the space ABC , multiplied by the circumference of that circle whose radius is GX , the distance of the center of gravity from $A B$.

Coroll. III. By having the area, and place of the center of gravity, of any curved or right-lined space given, we can cube the solid formed by the circumvolution of that figure, about either the ordinate or abscissa.

Coroll. IV. Having the magnitude of a solid, and the place of its center of gravity given, we can easily determine the area of the space by the circumvolution of which the said solid was produced.

CENTRUM, in geometry and mechanics, the same as center. See CENTER.

CENTRUM PHONICUM, in acoustics, the place where

where the speaker stands, in polysyllabic and articulate echoes.

CENTRUM PHONO-CAMPTICUM, the object or place that returns the voice in an echo. See the article **ECHO**.

Blancanus says, that no syllable can be distinctly and clearly returned, under the distance of twenty-four geometrical paces.

CENTRUM TENDINOSUM, in anatomy, a point wherein the tendons of the muscles of the diaphragm meet.

CENTRY-BOX, the same with the guerritte, only the former is of wood, and the other of stone.

CENTUNCULUS, in botany, a genus of plants, whose flower is monopetalous and rotated, the tube being globose, and the limb divided into four oval segments. It contains four filaments, top'd with simple antheræ. The fruit is an unilocular globose capsule, containing a great number of small roundish seeds.

CENTURION, among the Romans, an officer in the infantry, who commanded a century, or an hundred men.

CENTURY, in a general sense, any thing divided into or consisting of an hundred parts.

CENTURY, in chronology, the space of one hundred years. Church history is chiefly computed by centuries, beginning from our Saviour's birth.

CENTUSSIS, in Roman antiquity, a coin containing an hundred asses.

CEPA, the onion. See the article **ONION**.

CEPHALANTHUS, in botany, a genus of plants whose flowers are collected into a spherical head; each flower is monopetalous, and funnel-shaped. There are four filaments inserted in the corolla, which are shorter than the tube. The fruit is a globular hairy capsule of one cell, inclosing one or two oblong angular seeds; several of these grow together, and form a round head.

CEPHALIC, in a general meaning, signifies any thing belonging to the head or its parts.

CEPHALIC MEDICINES, are remedies for disorders of the head.

CEPHALIC VEIN, in anatomy, creeps along the arm between the skin and the muscles, and divides it into two branches; the external goes down to the wrist, where it joins the basilica, and turns up to the back of the hand: the internal branch, together with a small one of the basilica, makes the mediana.

CEPHALOPHARYNGÆI, in anatomy, the first pair of muscles of the upper-part of the gullet, which proceed from beside the head and the neck, and are spread more largely upon the tunic of the gullet.

CEPHEUS, in astronomy, a constellation of the northern hemisphere, whose stars, in Ptolemy's catalogue, are thirteen; in Tycho's eleven; in

Hevelius's, forty; and in Mr. Flamsteed's, thirty-five.

CERASTES, the horned snake, in zoology, is the name of a species of serpent, with two protuberances on its forehead, hard as a shell, and from which it has its name.

CERASTIUM, in botany, a genus of plants, whose flower consists of five bind obtuse petals, with ten filiform stamina, which are shorter than the corolla: these are terminated with roundish antheræ. The fruit is an ovato-cylindrical capsule, of one cell, opening at the top, and contains a great number of roundish seeds. This genus is the same with the myofotis of Tournefort.

CERATE, in pharmacy, the name of one of the sorts of topical medicines, softer than a plaster, and harder than an ointment.

CERATOGLOSSUM, in anatomy, the name of a pair of muscles, serving to draw the tongue directly into the mouth; but if only one of them acts, it draws the tongue to one side of the mouth.

CERASUS, the cherry-tree. See the article **CHERRY**.

CERATONIA, the carob-tree, in botany, a plant which produces a petalous flower; the fruit is a compressed pod, of about a span long, divided by transverse partitions, each having a roundish compressed seed, contained in a brown-coloured sweet pulp, which is used by the Egyptians and Arabians for the same intention as sugar.

This tree is very common in Spain, and in some parts of Italy, as also in the Levant, where it grows in hedges, and produces great quantities of pods. These are many times eaten by the poor inhabitants, when they have a variety of other food, but they are apt to loosen the belly, and cause gripings of the bowels. These pods are directed by the college of physicians to enter some medicinal preparations; for which purpose they are often brought from abroad. With us it is raised in the gardens of the curious: the leaves are evergreen; and as they differ in shape from most other plants, they make an agreeable variety in the green-house. This plant is here propagated from seeds: they should be sown in the spring, on a hot-bed: when the plants are up, they should be transplanted into pots, and afterwards inured by degrees to the open air, as the summer advances.

This plant is the same with the filiqua of Tournefort.

CERBERA, in botany, a genus of pentandrous plants, whose flower consists of a pentaphyllous acuminate calyx; the corolla is monopetalous and funnel shaped, having a long tube open at the top, and divided into five large segments; in the middle of the tube are placed five subulated filaments, topped with erect antheræ. The fruit is a large round fleshy drupe, marked with a longitudinal furrow on the side, and containing two cells, in each of which is a single large compressed nut.

There

There are three species in this genus, one of which grows in the Braßils and the Spanish West-Indies in plenty; also some in the British islands in America. This sort rises with an irregular stem to the height of eight or ten feet, sending out many crooked diffused branches, which toward their tops are furnished with thick succulent leaves, about three inches long and near two broad, of a lucid green, smooth, and very full of a milky juice, as is every part of the tree. The flowers come out in loose bunches at the extremity of the branches, and are of a cream colour. The wood of this tree stinks most intolerably, and the kernels of the nuts are a deadly poison, so that the Indians always caution their children against eating them, for they know of no antidote to expel this poison: nor will any of them use this wood for fuel; but they take the kernels out of the shells, into which they put small stones, then bore a hole through each shell, and string them, these they tie about their legs to dance with as the morrice-dancers use bells with us.

CERCIS, the Judas-tree, in botany, a plant which grows naturally in the south of France. In Spain and Italy it rises with an upright trunk to the height of twelve or fourteen feet, covered with a dark reddish bark, and divides upward into many irregular branches, which are furnished with round, heart-shaped smooth leaves, placed irregularly on the branches, with long foot-stalks: these are of a pale green on their upper, and of a greyish colour on their under-side, and are deciduous. The flowers come out on every side of the branches, and many times from the stem of the tree in clusters; these are of a bright purple colour, papilionaceous, and stand on short foot-stalks; the corolla of the flower consists of five petals inserted into the calyx; the fruit is an oblong obliquely acuminate legumen, having one cell, containing a row of roundish seeds, annexed to the upper suture.

This tree is usually planted with us among other flowering trees and shrubs for the ornament of the flower-garden, and blossoms in May; it is propagated by sowing the seeds in the spring upon a bed of light earth, and afterward transplanted into the nursery.

The wood of this tree is very beautifully veined with black and green; it takes a fine polish, and may be converted into many uses.

There is another species of *cercis*, which is a native of North America, where it is called the red-bud-tree.

CERBERUS, the name of a dog, with three heads, whom the poets made to be the porter of the infernal regions.

CERDONIANS, in church history, ancient heretics, who maintained most of the errors of Simon Magus, Saturnel, and other Gnostics.

CEREALIA, in antiquity, the sacred rites of the goddess Ceres, instituted by Triptolemus.

CEREBELUM, in anatomy, the hinder part of the brain. See the article **BRAIN**.

CEREBRUM, in anatomy, denotes the brain. See the article **BRAIN**.

CEREMONY, *Ceremonia*, an assemblage of several actions, forms, and circumstances, serving to render a thing more magnificent and solemn; particularly used to denote the external rites of religious worship, the formalities of introducing ambassadors to audiences, &c.

CERES, a Pagan deity, the inventor, or goddess of corn.

CEREUS, the torch-thistle, in botany, a genus of plants, whose flower is composed of a number of narrow pointed petals, which are radiated: in the base of the petals are inserted a great number of declining stamina. The fruit is an oblong, succulent berry, with a prickly skin, filled with small seeds, inclosed in a pulp.

There are divers species in this genus, some of which grow upright, others trail on the ground; but are all succulent, and without leaves.

The large upright torch-thistle has six large angles, which are far asunder. Their edges are armed with sharp spines, which come out in clusters at certain distances, spreading like a star. The outer substance of the stem is soft, herbaceous, and full of juice; but in the center there is a strong fibrous circle, running the whole length, which secures the stem from being broke by the winds.

This plant will rise to the height of thirty or forty feet, provided their tops are not injured. The flowers come out from the angles on the side of the stem, on a thick fleshy footstalk, which is scaly, round, channeled, and hairy. The duration of these flowers is very short.

As this plant is housed in winter, when it is got so high that the place cannot contain it any longer, it may be cut off near the bottom in the summer, and laid in the stove to heal the place of incision, after which it may be stuck in the bark-bed, where it will soon and readily take root; when it may be planted in a pot: the other part will put forth from the top fresh plants, which is the only method to increase them. This plant is not so tender as the other sorts, therefore may be kept in a common green-house in winter; but they should have scarce any water, for unless they are placed in a hot-house, where the moisture is soon evaporated, the wet will occasion them to rot. This species grows naturally at Surinam, from whence it was first brought to Holland, and is now very common in England.

Of the creeping or trailing sorts, there is one which opens its flower in the evening, is fully expanded at midnight, and the next morning decayed. This is large and radiated.

Another sort, which is now pretty common, produces very beautiful flowers, of a rich pink colour. The petals are not so numerous; and the tube of the

the flower is longer than those of the other species; and contrary to all the other sorts, keep open three or four days, provided the weather is not too hot. During the continuance of these flowers, which may be a fortnight or three weeks, as they do not all come out together, they make a most beautiful appearance in the house. This sort has very slender trailing branches, which some train up to sticks, which, being turned in serpentine order, have somewhat the appearance of snakes; others let them hang down the sides of the pots. This plant for the oddity of its appearance, and the great plenty of its beautiful flowers, may be placed among the first class of exotic plants. It is very easily propagated by cuttings in the summer months, which should be laid in a dry place to heal for about a fortnight, and afterward stuck in the tan-bed, where they will easily take root; after which they may be potted, and kept in the hot-house in winter, though they may be preserved with care in a good green-house; but must have very little water.

This genus of plants are classed by Linnæus with the melon, thistle, Indian-fig, &c. under the general name *caelis*: but though the flowers may agree, yet as the plants are so very different from each other in their appearance, we therefore thought it necessary in this work to explain them by the names they are most generally known by.

CERINTHE, honey-wort, in botany, a genus of plants, the flower of which consists of a single petal; the tube is short and thick, the limb is thicker than the tube, and somewhat bellied: it is divided into five segments, and the mouth is open and pervious: the fruit consists of two hard osseous bodies of an oval figure, gibbous on the outside, plane within, acute, emarginated, and containing two cells: the seeds are single, roundish, and accuminated.

Botanists enumerate five species of this genus, which are all natives of foreign countries.

CERINTHIANS, christian heretics, followers of Cerinthus, who lived, and published his heresy, in the time of the apostles themselves; for Epiphanius places him in the year of Christ 80, in the reign of Domitian. He had been circumcised, and was probably of Jewish extraction.

The particulars in which the heresy of the Cerinthians consisted were these: they did not allow that God was the author of the creatures; but said, that the world was created by an inferior power: they attributed to this creator an only son, but born in time, and different from the word. They admitted several angels and inferior powers, as silence, depth, fulness: in which they were afterwards followed by the Valentinians. They maintained that the law and the prophets came not from God, but from the angels; and that the God of the Jews was only an angel.

As to our Saviour, the Cerinthians distinguished

between Jesus and Christ: they said that Jesus was a mere man, born like other men, of Joseph and Mary; but that he excelled all others in justice, prudence, and wisdom: that Jesus being baptized, the Christ of the supreme God, that is, the holy spirit, descended upon him; and that, by the assistance of this Christ, Jesus performed his miracles: that Jesus suffered, and rose again, but that the Christ had before left him, and returned to heaven.

CEROPEGIA, in botany, a genus of pentandrious plants, whose flower is composed of a small quinque-lobed calyx, with a monopetalous corolla, large and globose at the base, with a cylindraceous tube, and a small limb, cut in five segments: in the base of the corolla is placed five small incurved stamina. The pericarpium is composed of two cylindraceous pointed folliculi unilocular, and of one valve. The seeds are numerous, imbricated, oblong, and crowned with down.

CERTIFICANDO DE RECOGNITIONE STAPULÆ, a writ issued to the mayor of the staple, commanding him to certify to the lord-chancellor a statute-stable taken before him, where the party refuses to bring it.

CERTIFICATE, in law, a writing made in any court, to give notice to another court of any thing done therein. The clerks of the crown, assize, and the peace, are to make certificates into the King's-Bench, of the tenor of all indictments, convictions, outlawries, &c.

CERTIFICATION of *Assize of novel Disseisin*, a writ granted for re-examining passed by assizes, before justices. This writ is used where a person appears, by his bailiff, to an assize brought by another, and has lost the day.

CERTIORARI, a writ which issues out of the chancery, directed to an inferior court, to call up the records of a cause there depending, in order that justice may be done: and this writ is obtained upon complaint that the party who seeks it has received hard usage, or is not like to have an impartial trial in the inferior court. A certiorari is made returnable either in the King's-Bench, Common-Pleas, or in Chancery.

CERT-MONEY, a fine paid yearly by the residents of several manors to the lord thereof, and sometimes to the hundred, *pro certo lete*; that is, for the certain keeping of the leet.

CERVICAL NERVES, in anatomy, are eight pair of nerves, so called, as having their origin in the neck. See **NERVE**.

CERVICAL VESSELS, in anatomy, denote the arteries, veins, &c. which pass through the vertebræ, and muscles of the neck, up to the skull.

CERVICALES DESCENDENTES, a pair of muscles, antagonists to the sacro-lumbares, coming from the third, fourth, fifth, and sixth vertebrae of the neck.

CERVIX, in anatomy, denotes properly the
binder

hinder part of the neck, as contradistinguished from the fore part, called *jugulum*, or the throat. See **NECK**.

CERVIX of the *Uterus*, or the neck of the uterus, that oblong canal or passage between the internal and external orifices of the womb, which receives and incloses the penis, like a sheath; whence it is also called *vagina*. See the articles **UTERUS** and **VAGINA**.

CERUMEN, ear-wax, or that natural excrement collected in the meatus auditorius, and discharged from the glands of those parts through the membrane which lines them. It is fluid on its first discharge, but by its continuance it becomes thicker, more solid, viscid, of the consistence of clay, and of a bitterish taste.

CERUSE, or **CERUSS**, white-lead, a sort of calx of lead, made by exposing plates of that metal to the vapour of vinegar.

CERUSS of *Antimony*, a medicine prepared by distilling powdered regulus of antimony with spirit of nitre, till no more fumes arise; what remains in the retort, being pulverised and washed, makes the ceruss of antimony, which is esteemed a powerful diuretic.

CERVUS, the stag or deer-kind, in zoology, a genus of quadrupeds of the order of the pecora; the characters of which are, that they have deciduous horns, at first hairy, and afterwards naked and smooth; add to this, that there is only one dog-tooth on each side of the upper jaw, and that placed at a distance from the other teeth.

Under this genus are comprehended the camelpardalis, the alce or elk, the rangifer or rein-deer, the capreolus, and the stag and fallow-deer. See the articles **CAMELO-PARDALIS**, &c.

CERVUS VOLANS, in zoology, the name of the stag-horned beetle, a remarkably large species of beetle, with its horns deeply jagged or ramified, somewhat like those of a stag.

CESARE, among logicians, one of the modes of the second figure of syllogisms, the minor proposition of which is an universal affirmative, and the other two universal negatives: thus

Ce. No immoral books ought to be read:

sa. But every obscene book is immoral:

re. Therefore no obscene book ought to be read.

CESSION, in law, an act by which a person surrenders and transmits to another person, a right which belonged to himself.

CESSION, in the ecclesiastical law, is when an ecclesiastical person is created a bishop, or when a parson of a parish takes another benefice without dispensation, or being otherwise qualified. In both these cases their first benefices become void by cession, without any resignation.

CESTRUM, in botany, a genus of plants, the flower of which is monopetalous, of a funnel-form,

with a cylindrical and very long and slender tube, and a plane plicated limb, divided into five equal ovated segments; the fruit is an oblong oval berry, with one cell, containing numerous roundish seeds.

CESTUS, among ancient poets, a fine embroidered girdle said to be worn by *Venus*, to which *Homer* ascribes the faculty of charming and conciliating love.

CETACEOUS, an appellation given to a class or order of fishes, otherwise called *plagiuri*. See the article **PLAGIURI**.

CETERACH. See the article **ASPLENIUM**.

CETUS, or the *Whale*, in astronomy, a constellation of the northern hemisphere, containing, according to Ptolemy, 22 stars, Tycho 21, but in the following catalogue 97. The poets tell us that this is that monstrous fish that would have devoured *Andromeda*; but, being overcome by *Perseus*, was afterwards translated into heaven by *Jupiter*, for the hugeness of its bulk.

CEVADILLA, in botany, Indian caustic barley, the seed vessel of a Mexican plant, resembling in its form and structure a barley ear, but with smaller seeds, not above the size of linseed.

CHÆROPHYLLUM, chervil, in botany, an umbelliferous plant, with winged leaves somewhat like those of parsley, producing smooth longish seeds, shaped like a bird's beak. It is a native of the southern parts of Europe, and sown annually with us in gardens.

CHAFERY, a forge in an iron-mill, where the iron is hammered out into complete bars, and brought to perfection.

CHAFE-WAX, an officer in the chancery, who fits the wax for sealing writs, patents, and other instruments issued out from thence.

CHAFF, in husbandry, the refuse or straw that is separated from corn, by screening or winnowing it.

CHAFFERCOUNCES, printed linen manufactured in the Mogul's dominions, and imported to Europe by way of Surat.

CHAFPEZS, in our old records, signify wares or merchandize; and hence the word chaffering is used for buying and selling.

CHAIN, *Catena*, a long piece of metal composed of several links, or rings, engaged the one in the other. They are made of divers metals, some round, some flat, others square; some single, some double; and serve for so many uses, that it would be tedious to give a particular account of them all.

CHAIN also implies a string of gold, silver, or steel-wire, wrought like a tidue, which serves to hang watches, tweezer cases, and other valuable toys upon. The invention of these piece of workmanship was derived originally from England, whence foreigners give them the name of chains of England.

CHAINS, in naval affairs, strong plates or links of iron bolted to the timbers on each side of all the masts, by which the shrouds of the masts are drawn tight and fastened. There is a broad plank or thick scaffold,

scaffold, called the channel, placed edge-ways on the ship's side, through which they pass in order to keep the shrouds off the upper-rails and gunnels; that is, the upper part of the ship's side.

CHAIN-SHOT, in artillery, is formed by having a shot chain which fastens two cannon-balls together. These are more particularly used in the service for cutting and mangling a ship's rigging, and carrying away her masts.

CHAIN-PUMP. See the article **PUMP**.

CHAIN, in surveying, an instrument usually made of iron-wire, but sometimes of brass, divided into an hundred equal parts, called links, and is used in measuring lengths in surveying of land; and if other proper instruments for taking or measuring angles are wanting, it may be used with great propriety for that purpose, and rather preferable to any other for expedition, accurateness, where the bearings are not required, or an accurate plot is not wanted, but only the true content of a piece of land. These chains are of different or various sorts, viz.

1. A chain of 100 feet long, each link consequently one foot long; at each tenth foot there is a plate of brass with a figure engraved upon it, shewing readily how many links are from the beginning of the chain; and for more ease in reckoning, there is, or should be a brass ring at every five links, that is one between every two plates.

2. A chain of $16\frac{1}{2}$ feet long, and made so as to contain a hundred links, with rings at every tenth link. This chain is most useful in measuring gardens or orchards by pole or perch measure.

3. A chain of four poles or perches in length, called Gunter's chain, being sixty-six feet, or twenty-two yards, which being divided into one hundred parts, or links, each link consequently must contain 7.92 inches. It is usual to put pieces of brass at every tenth link, and that at the fiftieth link is round, but all the rest are forked, or cut with points. Thus at ten links, from the beginning, is a piece of brass with one horn or point; at twenty with two, at thirty with three, at forty with four, and at fifty a round piece. Likewise it must be remarked, that it does not proceed from from fifty to sixty, but from each end to fifty. This chain is what is commonly used by surveyors, and is of all others most useful. Sometimes instead of the forked points abovementioned in the pieces of brass, they are all made round, with each a proper number of holes to distinguish them, but these are not so good, the holes being apt to fill with dirt, and cause mistakes, which in every thing ought carefully to be avoided as much as possible.

When any line, side of a field, &c. is to be measured with this chain, you need not regard any other denomination but chains and links, which set down in the same manner as decimals: thus, if the side or line measured be 7 chains, 47 links, you

must write it down thus, 7.47, which is nothing more than expressing it decimally seven chains, and for seven one-hundredths. Again, if it was fifteen chains nine links you had to put down, write it thus, 15.07, always remembering, if the links to be writ down are under ten, to place a cypher before the quantity, as in the last.

The method of surveying a field or piece of land with the chain, we shall shew by the following example, viz.

Let *ABCDEF* represent the field, whose content is required. First, Draw a rough sketch of the outlines of the place by the eye, likewise of the pricked lines, as represented in the figure. Second, Set off with the chain any convenient number of links, as 30, 40, or 50, from *A* to *c*, and the same from *A* to *d*; then measure from the point *c* in the line *AC* to the point *d* in the line *AF*, and you have the chord *cd* of the angle *A*. Third, Measure the line *Aa* with the chain. Fourth, Measure *aB*, so that it shall be perpendicular to *AC*, which you may easily do with a cross-staff; then proceed to measure the line *aC*, *CD*, *DE*, *bE*, (in the same manner as *aB*) and *bF*, and you will have all the dimensions required for either plotting the field, or finding the true content; the nature of which, and every other requisite, shall be given under the article **SURVEYING**.

CHAIR, *Cathedra*, was anciently the suggestion, or pulpit, whence the priest or public orator spoke to the people. See the article **CATHEDRA**.

Curule **CHAIR**, an ivory seat placed on a car, wherein were seated the chief magistrates of Rome, and those to whom the honour of a triumph was granted.

CHAIR-MAN, the president or speaker of an assembly. See **PRESIDENT**.

CHALAZA, among naturalists, a white knotty sort of string at each end of an egg, formed of a plexus of the fibres of the membranes, whereby the yolk and white are connected together. See **EGG**.

CHALCEDONY, *Chalcedonius*, in natural history, a genus of semi-pellucid gems, of an even and regular, not tabulated texture; of a semi-opaque, crystalline basis, and variegated with different colours, dispersed in form of mists and clouds; and, if nicely examined, found to be owing to an admixture of various kinds of earths, but imperfectly blended in the mass, and often visible in distinct molecules.

CHALCIDICA, or **CHALCIDICUM**, in ancient architecture, a magnificent hall belonging to a tribunal or court of justice.

CHALCITIS, the name given by the ancients to the brownish-red chalcantum, of a soft and friable substance, and shewing a very irregular surface when broken; being composed of five or six series of short, waved, and undulated striae.

CHAL-

CHALDRON, an English dry measure, consisting of thirty-six bushels, heaped up according to the sealed bushel kept at Guild-hall, London : but on ship-board, twenty-one chaldron of coals are allowed to the score.

CHALICE, the cup or vessel used to administer the wine in the sacrament; and by the Roman Catholics in the mass.

CHALK, in natural history, the English name of the white, dry marle, with a dusty surface, found in hard masses, and called by authors, *creta*, and *terra creta*.

Black CHALK, among painters, denotes a kind of ochreous earth, of a close structure, and fine black colour, used in drawing upon blue paper.

Red CHALK, an indurated clayey ochre, common in the colour-shops, and much used by painters and artificers.

CHALKY-LAND, that lying on a chalky bottom, whereby it is strongly impregnated with the virtues of the chalk.

CHALLENGE, a cartel, or invitation to a duel, or other combat. See the article **DUEL**.

CHALLENGE, in law, is an exception made to jurors, who are returned to a person on a trial.

CHALYBEAT, in medicine, an appellation given to any liquid, as wine or water, impregnated with particles of iron or steel.

CHAMADE, in war, a signal made by beat of drum for a conference with the enemy, when any thing is to be proposed; as a cessation of arms to bring off the dead, or a signal made by the besieged when they have a mind to deliver up a place upon articles of capitulation: in which case there is a suspension of arms, and hostages delivered on both sides.

CHAMÆDRYS, in botany. See **TEUCRIUM**.

CHAMÆLEON, *Chamæleo*, in zoology, a species of lizard with a short rounded tail, five toes on each foot, two or three of which adhere together. See **LIZARD**.

CHAMÆMELUM, camomile, in botany, a plant with finely divided leaves; and moderately large flowers, standing solitary on the tops of the stalks, upon long naked pedicles: the flower is composed of a number of white petals, set round a yellow convex disk.

The leaves and flowers of this plant have a strong, not ungrateful smell; and a very bitter nauseous taste.

CHAMÆPITYS, ground-pine, in botany, a low, hairy, creeping plant, with square stalks; whitish clammy leaves, cut deeply into three long narrow segments, like those of the pine-tree, set in pairs at the joints; and yellow labiated flowers, without pedicles, and wanting the upper lip. It is annual, grows wild in sandy and chalky grounds in some parts of England, and flowers in July.

CHAMÆROPS, the dwarf palm or palmetto, in botany, a plant which has no stem, but the foot-stalks of the leaves rise immediately from the root, and are armed on each side with strong spines; they are flat on their upper surface and convex underneath. To the ends of these foot-stalks the center of the leaves are fastened, which spread open like a fan, having many foldings, and at the top are deeply divided like the fingers of the hand; when they first come out they are closed together like a fan when shut, and are fastened together by strong fibres, which run along the borders of the leaves; when the leaves spread open, these fibres or strings hang from the sides and ends; the borders of the leaves are finely sawed with narrow edgings; these leaves spread out on every side of the plant.

From between the leaves comes out the spadix or club which sustains the flowers: this is covered with a thin spatula or hood, the flowers are male and hermaphrodite; the petals are ovated, acute, and inflexed at the top. The fruit consists of three round berries with one cell, containing solitary globose seeds.

The corolla of the male flower is the same as the hermaphrodite.

This plant grows naturally in Andalusia, where in sandy land the roots spread, and propagate very fast, as fern does in England. The leaves of this plant are used as brooms to sweep with. Another sort of palmetto grows naturally in the West-Indies, which differs chiefly in the size, and are without spines.

CHAMANIM, in Jewish antiquity, idols exposed to the sun upon tops of houses, according to Rabbi Solomon: others will have the chamanim to be the same with what the Greeks call *pyraea*; that is, portable chapels, or temples, made in the form of chariots, in honour of the sun. See the article **PYRÆA**.

CHAMBER, in building, any room situated between the lowermost and the uppermost rooms: in most houses there are two, in others three, or more stories of chambers.

CHAMBER, in policy, the place where certain assemblies are held, also the assemblies themselves. Of these, some are established for the administration of justice, others for commercial affairs.

CHAMBER of a Cannon, in artillery, that part of the bore of a cannon which receives the powder with which it is charged. See the article **CANNON**.

It is evident that the greater the quantity of powder which takes fire at the same instant, the greater its effect will be upon the bullet. This gave rise towards the end of the last century, to a new construction of the bore of cannon, by making a cavity in the form of a sphere a little flattened. The touch-hole being placed pretty near the middle of this cavity, which was larger than any other part of

the

the bore, fired a greater quantity of powder at the same time than if the bore had been uniform, and then the powder finding itself, as it were, bound up, and confined in this cavity, acted upon the bullet with more force and impetuosity than in the common pieces.

The design of this contrivance was to throw a bullet from a piece shorter, lighter, and more easy of carriage, than others, with the same degree of force as from those before used. Experience proved that the construction of these pieces answered the end proposed; for though much shorter than other cannon, and charged with a less quantity of powder, they produced the same effect. But as it was difficult to clean the chamber after the piece had been fired, there frequently remained some sparks behind; so that when it was necessary to fire the pieces as fast as possible, many cannoneers had their arms shot off as they were charging them; and besides, as the powder, before it forced itself out of the chamber pressed on all sides with great violence and impetuosity, in a very little time the carriages were broken to pieces, and rendered unserviceable; and by a frequent repetition of this violent agitation, the piece acquired a very considerable recoil, and the direction of the bullet became uncertain. For these reasons this contrivance was entirely laid aside, and the greatest part of these pieces found in the arsenals and fortifications were re-cast; so that the cannon now used have a bore of the same diameter in all parts.

The pieces with spherical or oblong cavities, were called *spherical chamber-pieces*; and those used before and since that invention, are called *cylindrical chamber-pieces*.

We have already said, that the bore of cannon is in every part of equal diameters, but it must be observed, that this is not strictly true at present, except in twelve, eight, and four pounders; for in twenty-four and sixteen pounders, there is made at the bottom of the bore a little cylindrical chamber *a, b*, in fig. 2. Plate XXVII. which holds about two ounces of powder.

CHAMBER of a Mine, the furnace or cavity at the inner-end of the mine that receives the charge of powder, by which it is blown up. See the articles CHARGE, GALLERY, MINE.

The design of mines is to blow up and destroy whatsoever lies over their chambers; and in order to this, it is necessary that the powder they contain should meet with less resistance in this part than towards the gallery, otherwise it would not blow up.

When the quantities of powder requisite to charge the mine is known, what ought to be the dimensions or capacity of its chamber is to be thence ascertained.

The chamber must be of a size just sufficient to contain the charge it is to receive, that the powder

being more confined, may, when inflamed, have a stronger effect. It must also be of the figure of a cube, that is, a solid terminated by six equal squares, because the powder taking fire in the middle of this solid, acts more equally on all parts of the chamber of the mine, than if it had any other figure, except it could be made circular, which would be still better, but the construction of it in this figure is too difficult.

The proper dimensions of the chamber may be easily determined by geometry, knowing only the weight of a cubic foot of powder, which is found to be about eighty pounds; as, for instance, if a mine is to be charged with eighty pounds of powder, its chamber must be equal to one cubic foot. It may however be made about one-third larger than the space filled by the powder, because, to prevent the powder from growing damp in the chamber, or furnace, it is covered all round with sacks, planks, straw, &c.

To fix then the proper dimension of the chamber of the mine, for which we have above ascertained the proper charge, let us suppose, that to ninety-three pounds and an half, the quantity given by the calculation, seven pounds and a half be added, there will then be one hundred pounds complete for the charge. Now if eighty pounds of powder occupy one cubic foot of space, one hundred pounds will occupy one cubic foot and one quarter; add to this three quarters of a foot for the sacks, planks, straw, &c. which are to be placed in the mine, and two cubic feet will be given for the whole capacity of the chamber. So that nothing more is requisite than to find the side of a cube, containing two cubic feet, which appears by approximation, to be about one foot three inches; and then giving for the base of the chamber a square, whose side is equal to that just found, and making its height also equal to the same, it will have exactly the dimensions required. It may not be amiss to observe, that a rigorous exactness is not absolutely necessary in this sort of calculation.

CHAMBER of a Mortar, is situated in the same place, and destined for the same purpose, as the chamber of a cannon explained above. See the articles BOMB and MORTAR.

Some mortars have cylindrical chambers, which they call *old fashion*; some have spherical chambers, others chambers in the shape of a pear; there are others with chambers shaped like the frustum of a cone.

The mouths of mortars are from six to eighteen inches diameter; the chambers are bigger or less, according to the size of the piece, and they contain from two to twelve, and even to eighteen pounds of powder.

CHAMBER of a Pump. See the article PUMP.

CHAMBRANLE, among builders, an ornament of stone or wood bordering the three sides of doors, windows,

windows, and chimnies. It is different, according to the several orders, and consists of three parts, viz. the top called the traverse, and the two sides, the ascendants.

CHAMFER, or **CHAMFRET**, in architecture, an ornament consisting of half a scotia, being a kind of a small furrow or gutter on a column, called also *scapus*, *fria*, &c.

CHAMFERING, in architecture, a term used for the cutting the under edge of any thing aloope or level.

CHAIMOIS, or **CHARMOIS-GOAT**, in zoology, the name of the *capra*, a creature of the goat-kind, with erect and short but hooked horns.

It is from the skin of this animal that the chamois leather is made.

CHAMPADA, in botany, a genus of trees, producing polypetalous flowers, which are succeeded by a large fruit resembling a melon, much prized by the people of Malacca; it is when ripe twelve or fourteen inches long, and as much in circumference where broadest.

CHAMPAIN, or *Point CHAMPAIGN*, in heraldry, a mark of dishonour in the coat of arms of him who kills a prisoner of war, after he has cried quartet.

CHAMPARTY, or **CHAMPERTY**, in law, a contract made with either the plaintiff or defendant in any suit at law, for giving part of the land, profits, &c. sued for, to the party who undertakes the process at his own proper charges, provided he succeeds therein.

CHAMPIGNON, a plant of the fungus kind; it is less than the mushroom, pitted all round, and of a whitish red or brown; it is hollow on the inner side, and seems to be sprinkled with a sort of mealiness; though it is smooth, it differs from the common mushroom, not only in the size, but by the cavities, as well as by the colour of the under side.

The pedicle is entirely white, hollow, and furnished at the end with slender thready roots. The champignon, as well fresh as dried, has a sweetish taste, and is prepared in various manners for the table. Geoffroy affirms, it excites the appetite; increases the motion of the blood, and restores the strength, though it yields but little nourishment. They are in great esteem among the French, though some think all funguses are bad.

Champignons are found in meadows, and are common in divers parts of England, and frequently grow in circles.

CHANCE, in a general sense, a term applied to events, not necessarily produced, as the natural effects of any proper foreknown cause.

CHANCE is more particularly used for the probability of an event, and is greater or less, according to the number of chances by which it may happen, compared with the number of chances by which it may either happen or fail.

Dollrine of CHANCE, or Laws of CHANCE, is that art or method, by which (from certain rules) we discover the probability that any event has of happening or failing. Thus, supposing it were required to express the probability of throwing either an ace or duce at the first throw with a single die; then there being in all six different chances or ways that the die may fall, and only two of them for the ace or duce to come upward, the probability of the happening of one of those will be $\frac{2}{6}$, or $\frac{1}{3}$, and that of the contrary $\frac{4}{6}$, or $\frac{2}{3}$.

Or more generally, supposing there be a chances for the happening of an event, and b chances for the contrary; then the probability of happening will be $\frac{a}{a+b}$, and that of failing $\frac{b}{a+b} = 1$

— $\frac{a}{a+b}$. From hence it appears, that if the probability of the happening of an event, be subtracted from the unity, the remainder will be the probability of its failing; and *vice versa*.

The expectation on an event, is considered as the present certain value or worth, of whatever sum or thing is depending on the happening of that event, and is composed of that sum, and the probability of obtaining it. Therefore if the expectation on an event be divided by the value of the thing expected on the happening of that event, the quotient will be the probability of happening. For example, suppose A to throw once with a single die, on condition, that if either an ace or duce comes up, he shall be entitled to twenty shillings; then the probability of his receiving the said sum is $\frac{2}{6} \times 20s.$ or $\frac{20}{3}$ of 20s. will be the expectation in this case.

Again, suppose it was required to find the probability that two assigned events should both happen. Let the probability of the happening of the first of the two events be denoted by $\frac{a}{a+b}$, and that of

the second by $\frac{c}{c+d}$; and suppose the happening of

both to entitle a person B to the sum S. Now if the first of these should happen, it is manifest, that from that time till the second is determined, the expectation of B will be $\frac{c}{c+d} \times S$, or so much is the

sum that he might in that circumstance receive as an equivalent for his chance of obtaining that sum S. But his probability of getting into this circumstance, or being entitled to the value $\frac{c}{c+d} \times S$, being only

$\frac{a}{a+b}$, this expectation therefore, before either of

the events is decided, can be only $\frac{a}{a+b} \times \frac{c}{c+d} \times S$, or $\frac{a}{a+b} \times \frac{c}{c+d} \times S$; therefore the re-

quired.

quired probability of receiving it, or of both the events happening, is only $\frac{a}{a+b} \times \frac{c}{c+d}$, that is,

the probability that any two assigned events shall both happen, will be equal to the product of the probabilities of the happening of those events considered separately.

Coroll. Wherefore since the probability of the happening of each of these events may be compounded of the probabilities of the happening of two others, as well as that of receiving the sum 8 is of them two, &c. it follows, that the probability of the happening of any given number of events, i. e. that they shall happen, is equal to the product of all the probabilities of happening of those events considered singly.

For the manner of applying the doctrine of chances to gaming and annuities, see GAMING and INTEREST.

CHANCEL, a particular part of the fabric of a Christian church; or that part of the choir between the altar and the balustrade that incloses it, where the minister is placed at the celebration of the communion.

CHANCEL, among us, is also the rector's freehold and part of his glebe, and therefore he is obliged to repair it; but where the rectory is improper, the impropiator must do it.

CHANCELLOR, an officer supposed originally to have been a notary or scribe under the emperors, and named *cancellarius*, because he sat behind a lattice, called, in Latin, *cancellus*, to avoid being crowded by the people.

Lord High CHANCELLOR of Great Britain, or Lord Keeper of the Great Seal, is the highest honour of the long robe, being made so *per traditionem magni sigilli, per dominum regem*, and by taking the oaths: he is the first person of the realm next after the king and princes of the blood, in all civil affairs; and is the chief administrator of justice next to the sovereign, being the judge of the court of chancery.

CHANCELLOR of a Cathedral, an officer that hears lessons and lectures read in the church, either by himself or his vicar; to correct and set right the reader when he reads amiss; to inspect schools; to hear causes; apply the seal; write and dispatch the letters of the chapter; keep the books; take care that there be frequent preachings, both in the church and out of it; and assign the office of preaching to whom he pleases.

CHANCELLOR of a Diocese, a lay officer under a bishop, who is judge of his court. See the article BISHOP'S-Court.

CHANCELLOR of the Dutchy of Lancaster, an officer appointed chiefly to determine controversies between the king and his tenants of the dutchyl-land, and otherwise to direct all his majesty's affairs belonging to that court. See DUTCHY-Court.

CHANCELLOR of the Exchequer, an officer who presides in that court, and takes care of the interest of the crown.

CHANCELLOR of the Order of the Garter, and other military Orders, is an officer who seals the commissions and mandates of the chapter and assembly of the knights, keeps the register of their proceedings, and delivers acts thereof under the seal of their order.

CHANCELLOR of an University, is he who seals the diplomas, or letters of degrees, provision, &c. given in the university.

CHANCERY, the grand court of equity and conscience, instituted to moderate the rigour of the other courts that are bound to the strict letter of the law.

Apostolic CHANCERY, a court in the church of Rome, belonging to the pope.

CHANCER; in surgery. See the articles SHANKER and ULCER.

CHANDELIER, in fortification, a kind of moveable parapet, consisting of a wooden frame, made of two upright stakes, about six feet high, with cross planks between them; serving to support fascines to cover the pioneers.

The chandeliers differ from blinds only in this, that the former cover the men only before, whereas the latter cover them also above.

They are used in approaches, galleries, and mines, to hinder the workmen from being driven from their stations.

CHANFRIN, in the manege, the fore-part of a horse's head, extending from under the ears along the interval between the eye-brows down to his nose.

CHANGES of Quantities or Numbers, &c. in arithmetic, the same with what commonly in books of arithmetic is treated under the word permutation. See the article PERMUTATION.

CHANNEL, in architecture, the fossit of a cornice, which makes the pendant mouchette of the larmier.

CHANNEL of the Ionic Capital, is that part which is under the abacus, and lies open upon the echinus or eggs, which has its centers or turning on every side to make the volutes or scrolls.

CHANNEL of the Volute, in the Ionic capital, the face of the circumvolution, inclosed by a listel.

CHANNEL, in geography, is a narrow passage which separates two continents, and is the communication between a gulf and a sea, or between two seas, or between a continent and an island. Such are the British channel, St. George's channel, &c.

CHANNEL of a River, the bed of a river. See the article RIVER.

CHANNEL, in hydrography, is the deepest part of a river, harbour, or streight, which is rendered most convenient for the tract of shipping.

CHANNEL,

CHANNEL, in naval architecture, a broad thick plank, placed edgewise on a ship's side, abreast of all the masts: they are used to extend the shroud by which the mast is secured to a proper width. See the article **CHAINS**.

CHANNEL of the Mouth of a Horse, that concavity in the middle of the lower jaw, appointed for a place to the tongue; which being bounded on each side by the bars, terminates in the grinders. It should be large enough not to be pressed with the bit mouth.

CHANTLATES, in building, are pieces of boards nailed or fastened to the ends of the rafters, to support two or three rows of tiles, to make an eve to carry the rain water from the sides of the building.

CHANTOR, a singer in the choir of a cathedral. The word is almost grown obsolete, chorister or singing-man being commonly used instead of it.

CHANTOR is used by way of excellence for the precentor or master of the choir, which is one of the first dignities of the chapter.

CHANTRY, or **CHAUNTRY**, a church or chapel endowed with lands, &c. for the maintenance of one or more priests to say mass for the souls of the donors. Hence,

CHANTRY-RENTS, are rents still paid to the crown by the purchasers of those lands.

CHAOS, that confusion in which matter lay when newly produced out of nothing at the beginning of the world, before God, by his Almighty word, had put it into the order and condition wherein it was after the six days creation.

CHAPE, among scabbard-makers, denotes the metalline plate fixed on the end of a scabbard, to prevent the point of the sword from piercing through it.

CHAPE, among sportsmen, signifies the tip of a fox's brush.

CHAPÉAU, in heraldry, an ancient cap of dignity worn by dukes, being scarlet-coloured velvet on the outside, and lined with a fur.

It is frequently borne above an helmet instead of a wreath, under gentlemen's crests.

CHAPEL, or **CHAPPEL**, a place of divine worship, served by an incumbent under the denomination of a chaplain.

CHAPEL is also a name given to a printer's work-house, in which sense they say, the laws of the chapel, the secrets of the chapel.

CHAPERON, a covering for the head, formerly worn both by men and women. Hence it became the name of those little shields, containing death's heads, and other funeral devices, placed upon the foreheads of horses that drew hearses at pompous funerals.

CHAPERON of a Bit Mouth, signifies the end of

the bit that joins to the branch just by the banquet. In scatch mouths chaperon is round, in others it is oval.

CHAPITERS, in architecture, the crown, or upper part of a pillar. See **CAPITAL**.

CHAPLAIN, an ecclesiastic who officiates in a chapel.

CHAPLET, a string of beads used by the Roman catholics to count the number of their prayers. The invention of it is ascribed to Peter the hermit, who probably learned it of the Turks, as they owe it to the East-Indians.

CHAPLET, in architecture, a kind of baguette, or small ornament, cut, or carved into olives, beads, &c.

CHAPPE, in heraldry, the dividing an escutcheon by lines drawn from the center of the upper edge to the angles below, into three parts, the sections on the sides being of a different metal or colour from the rest.

CHAPTER, *Capitulum*, in ecclesiastical policy, a society or community of clergymen belonging to cathedrals and collegiate churches.

CHAPTER, in matters of literature, a division in a book for keeping the subject treated of more clear and distinct. St. Augustine compares them to inns, inasmuch as they refresh the reader, as these the traveller.

The three CHAPTERS, a famous phrase in ecclesiastical history, signifying a volume by Theodoret, an adherent of Nestorius, against St. Cyril.

CHAPTRELS, in architecture, the parts on which the feet of an arch stand, the same with impost. See **IMPOST**.

CHARACTER, *παράσημα*, in a general sense, denotes any mark whatever, serving to represent either things or ideas: thus, letters are characters, types, or marks of certain sounds, words, of ideas, &c. See the article **LETTER**, &c.

CHARACTERS in Algebra. The first letters of the alphabet, as *a, b, c, d, &c.* are generally the characters of the given quantities; and the last letters, as *x, y, z, &c.* the characters of the quantities sought. Some however use the consonants to represent the known, and the vowels to represent the unknown quantities.

m, n, r, s, t, &c. are the characters of indeterminate exponents, whether ratios or powers. Thus *x^m, yⁿ, z^r, &c.* imply undetermined powers of different kinds; *m x, n y, r z*, different multiples, or submultiples, of the quantities *x, y, z*, according as *m, n, r*, are either whole numbers or fractions.

+ *plus*, or *more*, is the sign of real existence of the quantity it stands before, and is called an affirmative or positive sign. It is also the mark of addition: thus *a + b*, or *6 + 9*, implies that *a* is to be added to *b*, or 6 added to 9.

6 Z

— *minus*,

— *minus*, or *less*, before a single quantity, is the sign of negation or negative existence, shewing the quantity to which it is prefixed to be less than nothing. But between quantities it is the sign of subtraction; thus, $a - b$, or $8 - 4$, implies b subtracted from a , or 8 after 4 has been subtracted.

= *equal*. The sign of equality, though Des Cartes and some others use this mark $\approx$; thus, $a = b$ signifies that a is equal to b . Wolfius and some others use the mark $\equiv$ for the identity of ratios.

$\times$ *into*, or *with*. The sign of multiplication, shewing that the quantities on each side the same are to be multiplied by one another, as $a \times b$ is to be read a multiplied into b ; 4×8 , the product of 4 multiplied into 8. Wolfius and others make the sign of multiplication a dot between the two factors; thus, $5 \cdot 4$ signifies the product of 5 and 4. In algebra the sign is commonly omitted, and the two quantities put together; thus, bd expresses the product of b and d . When one or both of the factors are compounded of several letters, they are distinguished by a line drawn over them; thus, the factum of $a + b - c$ into d , is wrote $d \times \overline{a + b - c}$. Leibnitz, Wolfius, and others, distinguish the compound factors, by including them in a parenthesis thus $(a + b - c) \cdot d$.

$\div$ *by*. The sign of division; thus, $a \div b$ denotes the quantity a to be divided by b . In algebra the quotient is often expressed like a fraction, thus $\frac{a}{b}$ denotes the quotient of a divided by b . Wolfius makes the sign of division two dots; thus, $12 : 4$ denotes the quotient of 12 divided by $4 = 3$. If either the divisor or dividend, or both, be compounded of several letters; for example, $a + b \div c$, instead of writing the quotient like a fraction, $\frac{a + b}{c}$, Wolfius includes the compound quantities in a parenthesis, thus $(a + b) : c$.

$\oslash$ *involution*. The character of involution.

ω *evolution*. The character of evolution, or the extracting of roots.

> or $\sqsupset$ are signs of majority; thus, $a > b$ expresses that a is greater than b .

< or $\sqsubset$ are signs of minority; and when we would denote that a is less than b , we write $a < b$, or $a \sqsubset b$.

$\sim$ is the character of similitude used by Wolfius, Leibnitz, and others: it is used in other authors for the difference between two quantities, while it is unknown which is the greater of the two.

$\therefore$ *is*. The mark of geometrical proportion disjunct, and is usually placed between two pair of equal ratios, as $3 : 6 :: 4 : 8$, shews that 3 is to 6 as 4 is to 8.

$\divdiv$ the mark of geometrical proportion continued, implies the ratio to be still carried on without interruption, as $2, 4, 8, 16, 32, 64 \divdiv$ are in the same uninterrupted proportion.

✓ *irrationality*. The character of a surd root, and shews, according to the index of the power that is set over it, or after it, that the square, cube, or other root is extracted, or to be extracted; thus, $\sqrt[4]{16}$, or $\sqrt[2]{16}$ or $\sqrt{(2)} 16$, is the square root of 16. $\sqrt[3]{25}$, the cube root of 25, &c.

This character sometimes affects several quantities, distinguished by a line drawn over them thus, $\sqrt[4]{b + d}$ denotes the square root of the sum of b and d . When any term or terms of an equation are wanting, they are generally supplied by one or more asterisks: thus in the equation

$y^2 + py + \frac{1}{2}p^2 + q$ } $= 0$, the term $\pm py$ vanishing, is marked with an asterisk, $y^2 * - \frac{1}{2}p^2 + q$.

CHARACTERS used in Astronomy.

Characters of the planets.

♄ Saturn	☉ Sun	☾ Moon
♃ Jupiter	♀ Venus	♁ Earth
♂ Mars	☿ Mercury	

Of the signs.

♈ Aries	♌ Leo	♊ Sagittarius
♉ Taurus	♍ Virgo	♏ Capricornus
♊ Gemini	♎ Libra	♐ Aquarius
♋ Cancer	♏ Scorpio	♑ Pisces

Of the aspects.

♌ or S Conjunction	♌ Trine
SS Semisextile	Bq Biquintile
* Sextile	Vc Quincunx
Q Quintile	g Opposition
□ Quartile	g Dragon's head
Td Tredecile	g Dragon's tail

Of time.

A. M. *ante meridiem*, before the sun comes upon the meridian.

O. or N. noon.

P. M. *post meridiem*, when the sun is past the meridian.

Besides the above characters in astronomy, there are a few more which were used by the late royal professors of astronomy, Dr. Bradley, and Mr. Bliss, in their Astronomical Observations, the knowledge of which may be of some importance to those into whose hands the observations may fall, as they are expected in a little time to be made public.

The first is two dots placed after any observation, thus, $\therefore$, which signifies that this observation is a little doubtful, and not to be depended upon. The second is four dots, placed after an observation: thus, $\therefore$, which signifies that the observation is very dubious, and must not be made use of for determining any motion in the heavens. The third is E C, in observations of the moon's altitude on the meridian, which signifies that the moon's center was estimated, or its altitude taken as near as possible, both the upper and lower limb, at that time being invisible from its near proximity to the sun at the time of observation.

Lastly,

C H A

one, because it is used almost throughout Europe in all sorts of calculations, consists of these ten digits, 1, 2, 3, 4, 5, 6, 7, 8, 9, 0.

The Roman numeral character consists of seven majuscule letters of the Roman alphabet, viz. I, V, X, L, C, D, M.

The I denotes one, V five, X ten, L fifty, C a hundred, D five hundred, and M a thousand.

The I repeated twice makes two, II; thrice, three, III; four is expressed thus IV, as I before V or X takes an unit from the number expressed by these letters. To express six an I added to a V, VI; for seven, two, VII; and for eight, three, VIII; nine is expressed by an I before X, thus IX.

The same remark may be made of the X before L or C, except that the diminution is by tens; thus, XL denotes forty, XC, ninety, and LX sixty. The C before D or M diminishes each by a hundred.

The number five hundred is sometimes expressed by an I before a C inverted, thus, IC; and instead of M, which signifies a thousand, an I is sometimes used between two C's, the one direct, and the other inverted, thus, CIO. The addition of C and O before or after, raises CIO by tens, thus CCIOO expresses ten thousand, CCCIOOO, a hundred thousand.

The Romans also expressed any number of thousands by a line drawn over any numeral less than a thousand; thus, $\overline{V}$ denotes five thousand, $\overline{LX}$ sixty thousand; so likewise $\overline{M}$ is one million, $\overline{MM}$ is two millions, &c.

CHARACTER, in epic and dramatic poetry, that which is peculiar in the manners of any person, and distinguishes him from all others.

CHARACTERISTIC, in a general sense, a peculiar mark or character whereby a person or thing is distinguished from all others.

CHARACTERISTIC of a *Logarithm*, the same with its index or exponent.

CHARACTERISTIC Triangle of a Curve, in the higher geometry, is a rectilinear right-angled triangle, whose hypothenuse makes part of the curve, not sensibly different from a right line.

It is so called, because curve lines are used to be distinguished hereby.

Suppose, for example, the semiordinate, p, m , (Plate XXXIII. fig. 2.) infinitely near another PM, then will Pp be the differential of the abscissa; and letting fall a perpendicular $MR = Pp$, RM will be the differential of the semiordinate: draw therefore a tangent TM , and the infinitely small arch Mm will not differ from a right line. Consequently MmK is a rectilinear right-angled triangle, and constitutes the characteristic triangle of that curve.

CHARAG, the tribute which the Christians and Jews pay to the Grand Signior.

CHARBON, in the manege, that little black spot or mark which remains after a large spot in the cavity of the corner teeth of a horse: about the seventh or eighth year, when the cavity fills up, the tooth being smooth and equal, 'it is said to be raised.

CHARCOAL, a sort of fuel consisting of wood charred or half burnt.

There are considerable differences in the coals of different vegetables, in regard to their habitude to fire: the very light coals of linen, cotton, some fungi, &c. readily catch fire from a spark, and soon burn out; the more dense ones of woods and roots are set on fire more difficultly, and burn more slowly: the coals of the blackberry-bearing alder, of the hazel, the willow, and the lime-tree, are said to answer best for the making of gunpowder and other pyrotechnical compositions, perhaps from their being easily inflammable: for the reduction of metallic calces those of the heavier woods, as the oak and the beech, are preferable, these seeming to contain a larger proportion of the phlogistic principle, and that, perhaps, in a more fixed state; considered as common fuel, those of the heavy woods give the greatest heat, and require the most plentiful supply of air to keep them burning; those of the light woods preserve a glowing heat, without much draught of air, till the coals themselves are consumed; the bark commonly crackles and flies about in burning, which the coal of the wood itself very seldom does.

Charcoal, in burning, is supposed to emit a peculiar vapour, which confined, and accumulated in a close room, proves poisonous to animals: there are, indeed, too many examples of fatal consequences from the burning of charcoal in close places; not, however, from the charcoal giving out any pernicious matter, but from the quality of the air of the room being altered by the fire: air that has passed through burning fuel is no longer capable of supporting either fire or the life of animals.

CHARGE, in artillery, the quantity of powder, shot, bombs, grenades, with which a cannon or mortar is loaded for execution. See the article **CARTRIDGE**.

Cannon are charged by putting down into the bottom of the bore, first a quantity of powder, one third, or one half the weight of the ball. This is done with an instrument *a*, Plate XXXIII. fig. *a*. called a ladle, which is a sort of spoon, generally made of copper, fixed to the end of a staff *d*, which is called its handle. Upon the powder is put in a wad of hay, pressed or beat down very well with the instrument *e*, called a rammer. Upon this hay is put the ball, to secure it in its place, another wad is well rammed down upon it: the touch-hole of the piece is then filled with powder, from the upper part of which a little train is laid that communicates with it. The use of this train is to prevent the explosion

Fig. 1. Plain Chart

Fig. 3. Centrepetal Force

Fig. 2. Character of a Curve

d Charge

Pent

Sight Piece

Priming Iron

of the powder that fills the touch-hole from operating directly upon the instrument used to fire the piece, which in this case might be forced out of the hand of the gunner; an inconvenience which is prevented by setting fire to the end of the train.

In the modern pieces, a little gutter or channel is made, above a line deep, and six wide, to prevent the wind from dispersing or blowing away the train. This channel reaches from the touch-hole to the shield, on which is carved the king's arms. See Plate XXXVII. *fig. 1.*

The cannon being pointed at the place which the bullet is intended to strike, the train is fired, and the fire immediately communicated to the powder in the touch-hole, by which it is further communicated to that in the piece; and this powder being kindled, dilates so as to occupy a much greater quantity of space than when in grains; and being thus dilated, it make an effort on every side to force itself out: the bullet making less resistance than the sides of the piece, upon which the powder presses at the same time, is driven out by its whole force, and acquires that violent motion, the effect of which is well known to the world.

In Plate XXXIII. all the instruments necessary for charging cannon are represented. Besides those already described, there is the maulkin, or sponge, *b*, which is used to clean the piece after firing, and to extinguish any sparks that may remain behind. This is a sort of brush, fixed to the end of a staff. To sponge a piece is to put in this instrument, and with it clean well the cavity, at the same time stopping the aperture of the touch-hole.

The figures *g*, *b*, *i*, represent maulkins or sponges of a different kind, made of sheep-skins, fixed to a proper handle.

The wad-hook *l*, called also a worm, serves to draw the charge when necessary.

The picker or priming-iron *g*, serves to clear the inside of the touch-hole, and render it fit to receive the prime, and is a kind of large iron needle.

The lint-stock *m*, is a long staff, to the end of which is fastened a match to fire the piece.

The chapiteau *n*, is a sort of little pent-house, made by two thin pieces of board, joined together at top, so as to form an angle of about one hundred degrees. This is set up over the touch-hole, to prevent the prime from being carried away by the wind, or wetted by the rain.

All the instruments above-mentioned, used in charging and managing a cannon, are called cannon furniture.

To charge a mortar (as in charging cannon) many instruments are necessary.

The principal are, a rammer of the same diameter as the piece, to ram in and beat down the wadding and turf which cover the powder; an iron scraper, to clean the bore and chamber of the mortar, and a little spoon to clean more particularly the

powder chamber; a wooden knife, of about a foot long, to force the earth close in round the sides of the bomb; there is need also of priming-irons, aiming wedges, and two lint-stocks.

The officer who directs the charging of the mortar, having ascertained the proper quantity of powder, causes it to be put into the chamber of the mortar, and then to be covered with a wad, well beat down with the rammer. Over these are put two or three shovel-fulls of earth, which are also well beat or rammed down; after which the bomb is placed upon this earth, as near the middle of the mortar as possible, with the fuse, or touch-hole, uppermost; more earth is then put in, and pressed down close all round the bomb, with the wooden knife just mentioned, so as to keep the bomb firm in the situation it is placed in. All this being done, the officer points the mortar, that is, gives the inclination necessary to carry the bomb to the place designed. When the mortar is thus fixed, the fuse is opened, the picker is also passed into the touch-hole of the mortar to clear it, and it is then primed with the finest powder. This done, two soldiers, taking each one of the lint-stocks, the first lights the fuse, and the other fires the mortar. The bomb, thrown out by the explosion of the powder, is carried to the place intended, and the fuse, which ought to be exhausted at the moment of the bomb's falling, sets fire to the powder it is charged with; this, immediately, by its explosion, bursts the bomb into splinters, which are thrown off circularly round the point the bomb falls upon, and do considerable damage on every side.

CHARGE, in heraldry, is applied to the figures represented on the escutcheon, by which the bearings are distinguished from one another: and it is to be observed, that too many charges are not so honourable as fewer.

CHARGE, in the manège, a preparation, or ointment, of the confluence of a thick decoction, applied to shoulder-splints, inflammations, and sprains of horses: the parts affected are rubbed, and chaffed with this composition, after which they should be covered with sinking paper.

CHARGE, or OVERCHARGE, in painting, an exaggerated representation of any person, wherein the likeness is preserved, but withal ridiculed: few painters have the genius to succeed in these charges. The method is, to pick out and heighten something amiss in the face, whether by way of defect or redundancy; thus, if nature has given a man a nose a little larger than ordinary, the painter falls in with her, and makes the nose extravagantly long; and so in other cases.

CHARGE of Lead denotes a quantity of thirty-six pigs.

CHARGED, in heraldry, a shield carrying some impress or figure is said to be charged therewith; so also when one bearing, or charge, has another

ther figure added upon it, it is properly said to be charged.

CHARGING, in military affairs, an assault made by an army, or any party of men on the enemy. See **ATTACK**.

CHARIOT, a half coach, having only a seat behind, with a stool at most before.

Triumphal CHARIOT was one of the principal ornaments of the Roman celebration of a victory. See **TRIUMPH**.

CHARISIA, in heathen antiquity, a nocturnal festival, kept in honour of the graces, and consisting chiefly of dancing; only that sweet-meats, called likewise *charisia*, were distributed among those present.

CHARITY, among divines, one of the three grand theological virtues, consisting in the love of God, and of our neighbour; or the habit and disposition of loving God with all our heart, and our neighbour as ourselves.

CHARITY, among moralists, is used for the effect of a moral virtue, and consists in supplying the necessities of others, whether with money, council, assistance, or the like.

CHARLES'S-WAIN, in astronomy, seven stars so situated in the constellation *Urfa Major*, that they something, or by some have been supposed to, represent the figure of a wain.

CHARLOCK, the English name of a plant called by botanists, *sinapis*. See the article **SINAPIS**.

Charlock is a very troublesome weed in corn-fields, where we find two species of it very common, viz. one with a yellow flower, and the other with a white one. To prevent its growth the farmers mix horse dung with their cow dung used in manure, as the last is very apt to breed the charlock. When a field of barley is much infested with it, they mow it down in May, when in flower, taking care only to cut it so low as just to take off the tops of the leaves of the barley.

CHARM, a term derived from the Latin, *carmen*, a verse, and used to denote a magic power, or spell, by which, with the assistance of the devil, forcerer, and witches, were supposed to do wonderful things, far surpassing the power of nature. These things are now sufficiently exploded.

CHARNEL, or **CHARNEL HOUSE**, a kind of portico, or gallery, usually in or near a church-yard, over which were anciently laid the bones of the dead, after the flesh was wholly consumed.

CHARRE, or **GILT-CHARRE**, a truttaceous fish, called by many *carpio*, and reckoned by *Artedi* a species of salmon, less than a foot in length, with five rows of teeth in its palate.

Red CHARGE is likewise a species of salmon, called by authors *umbra minor*: it is much of the same size with the former, with the belly-fin red, and the under-jaw a little longer than the upper-one.

CHART, or **SEA-CHART**, is a hydrographical map, or a projection of some part of the earth's superficies in plane, for the use of navigators.

Charts differ very considerably from geographical or land maps, which are of little or no use in navigation: nor are sea-charts all of the same kind, being constructed on very different principles; and are chiefly distinguished by the following names; plane-chart, mercator's-chart, and globular-chart.

Plane-CHARTS are such wherein the circles of latitude and longitude are laid down parallel, and every where of equal distance. These are very incorrect, and ought not to be put in use, unless they only represent a small piece, and that near the line; because they give the same extent or number of miles to a degree in those parallels near the pole, as those near the equator, which is so well known to every sailor to be erroneous, that there will be no occasion here to expatiate upon it.

To construct a plane chart, that shall contain from five degrees north latitude, to five degrees south latitude, and from seven degrees east, to seven west longitude; draw the meridian *AB*, (Plate XXXIII. fig. 3.) at pleasure, with a pencil; then from the point *A*, set off ten equal parts (taken from any convenient scale) towards the point *B*; which ten parts will be equal to the ten degrees of latitude, and will determine the point *B*. At right angles to the meridian *AB*, draw the lines *AD* and *BC*, which will represent the parallels of five degrees south latitude, and five degrees north latitude; and from *A* and *B*, in each line *AD* and *BC*, set off a quantity of equal parts, (taken from the same scale from which your degrees of latitude were taken) equal to the number of degrees in longitude your chart is to contain, and you will then determine the point *C* and *D*, which join by drawing the line *CD*. Through the several degrees, or equal parts before set off in the line *AB*, draw as many lines parallel to *BC* and *AD*: likewise through each division, in the line *BC* and *AD*, draw lines parallel to *AB* and *CD*, which will represent so many parallels of longitude, and so many meridians.

If you divide the right angles *A*, *B*, *C*, *D*, into eight equal parts, and draw lines from the angular points thereof through the several divisions of the arches, they will represent the rhomb lines upon the chart, which are of use in finding the bearings of places from each other. But to avoid the confusion which attends such a multiplicity of lines, we have here only extended them to the divisions in each quadrant, which will be found equally useful in finding the bearings of different places: for by laying a parallel-ruler on the two given places, and extending the other part to two of the quadrants, you will easily discover to which of the lines the ruler is parallel, which will be the bearing of the two places required. For the use of this chart, see **PLANE SAILING**.

Reduced CHART, or *Chart of Reduction*, is that wherein the meridians are represented by right lines, parallel to one another, but unequal; these therefore, it appears by construction, must correct the errors of the plane charts. But since the parallels should cut one another at right angles, these charts are defective, inasmuch as they exhibit the parallels inclined to the meridians.

Hence another kind of reduced charts has been invented, wherein the meridians are parallel; but the degrees thereof unequal. These are called Mercator's charts.

Mercator's CHART is that wherein the meridians and parallels are represented by parallel right lines; but the degrees of the meridian are unequal, still increasing as they approach the pole, in the same proportion as those of the parallels decrease; by means whereof the same proportion is preserved between them as on the globe.

This chart has its name from the author, who first proposed it for use, and made the first chart of this projection, N. Mercator: but the thought was not originally his own, as having been hinted at by Ptolemy near two thousand years before: nor is the perfection owing to him; our countryman, Mr. Wright, being the first who demonstrated it, and shewed a ready way of constructing it, by enlarging the meridian line by the continual addition of secants. For the construction and use of Mercator's chart, see *Mercator's SAILING*.

Globular CHART, a meridional projection, wherein the distance of the eye, from the plane of the meridian, upon which the projection is made, is supposed to be equal to the sine of the angle of 45° . This projection comes the nearest of all to the nature of the globe, because the meridians therein are placed at equal distances; the parallels also are nearly equidistant, and consequently the several parts of the earth have their proper proportion of magnitude, distance, and situation, nearly the same as on the globe itself.

Chorographic CHARTS, descriptions of particular countries. See *CHOROGRAPHY*.

Heliographic CHARTS, descriptions of the body of the sun, and of the maculae, or spots, observed on it. See *HELIOGRAPHY*.

Hydrographic CHARTS, sheets of large paper, whereon several parts of the land and sea are described, with their respective coasts, harbours, sounds, flats, rocks, shelves, sands, &c. together with the longitude and latitude of each place, and the points of the compass. See the article *MERCATOR'S Chart*.

Selenographic CHARTS, particular descriptions of the spots, appearances, and maculae of the moon. See the article *SELENOGRAPHY*.

Topographic CHARTS, draughts of some small parts of the earth only, or of some particular places, without regard to its relative situation, as London, York, &c.

CHARTER, in law, a written instrument or evidence of things acted between one person and another.

Great CHARTER, *MAGNA-CHARTA*. See the article *MAGNA-CHARTA*.

CHARTER of the King is where the king makes a grant to any person or body politic, as a charter of exemption, of privilege, pardon, &c.

CHARTER-LAND, such land as a person holds by charter; that is, by evidence in writing, otherwise termed freehold. See the article *FREEHOLD*.

CHARTY-PARTY, in commerce, a deed or writing indented; that is, made between merchants and sea-faring men, concerning their merchandise and maritime affairs.

A charter-party of affreightment, settles the agreement in relation to the freight of a ship and cargo, between the merchant and commander or master of the vessel. It binds the master to deliver the cargo in good condition at the place of discharge, &c.

In those charter-parties, if the dangers of the sea are excepted, it has been adjudged that such exception extends as well to any danger upon the sea from pirates or men of war, as to common dangers by shipwreck, tempest, &c.

CHARTIS REDDENDIS, in law, a writ that lies against a person, who having charters of feoffment delivered to him to keep, afterwards refuses to deliver them.

CHARYBDIS, a rock in the streight of Messina, between Italy and Sicily, much celebrated in the writings of ancient poets.

CHASE, a great quantity of ground lying open and privileged for wild beasts and wild fowl. Such is Enfield-chase.

A chase differs from a forest, inasmuch as it may be in the hands of a subject, which a forest in its proper nature cannot; and from a park, in that it is not inclosed, and hath more officers.

CHASING of Gold, Silver, &c. See the article *ENCHASING*.

CHASTE-TREE, in botany. See the articles *AGNUS CASTUS* and *VITEX*.

CHASTISEMENT, in the manege, the severe and rigorous effect of the aids; for when the aids are given with severity, they become punishments. See the article *AIDS*.

CHECK, or *CHECK-ROLL*, a roll or book, wherein is contained the names of such persons as are attendant and in pay to the king, or other great personages, as the household servants.

Clerk of the CHECK, in the king's household, has the check and controulment of the yeomen of the guard, and all the officers belonging to the royal family, allowing their absence or defects in attendance, or diminishing their wages for the same, &c. He also, by himself or deputy, takes the view of those

those that are to watch in the court, and has the fetter of the watch, &c.

Clerk of the CHECK, in the king's navy, is also the name of an officer invested with the like power at the several dock-yards.

CHECKY, in heraldry, is when the shield, or a part thereof, as a bordure, &c. is chequered, or divided into chequers or squares, in the manner of a chess-board.

This is one of the most noble and ancient figures used in armory; and a certain author says, that it ought to be given to none but great warriors, in token of their bravery; for the chess-board represents a field of battle, and the pawns of men, placed on both sides, represent the soldiers of the two armies, which move, attack, advance, or retire, according to the will of the two gamesters, who are the generals.

This figure is always composed of metal and colour: but some authors would have it reckoned among the several sorts of furs.

CHEEK, in anatomy, that part of the face situated below the eyes, on each side. Wounds of the cheeks, if small, may be cured by the dry suture; but if large, the bloody one must be used. See the article *SUTURE*.

CHEEKS, among mechanics, are almost all those pieces of their machines and instruments, that are double, and perfectly alike; as the cheeks of a mortar, which are made of strong wooden planks, of a semi-circular form, bound with thick plates of iron, and fixed to the bed with four bolts: these cheeks rise on each side the mortar, and serve to keep it at what elevation is given it: the cheeks of a printing-press are its two principal pieces, placed perpendicular and parallel to each other, and serving to sustain the three forms, &c.

CHEEKS of the Mast, in naval affairs, certain projecting parts situated on the upper-end of the mast for sustaining the weight of the top-mast which rest upon them below, and is kept steady above by the cap. See *CAP* and *TRUSSEL-TREES*.

CHEESE, *Caseus*, a sort of food, prepared of curdled milk, purged from the serum of whey, and afterwards dried for use.

There is likewise a kind of medicated cheese, made, by intimately mixing the expressed juice of certain herbs, as sage, balm, mint, &c. with the churd, before it is fashioned into a cheese.

CHEESE-RUNNET, in botany, the same with the gallium of authors. See the article *GALLIUM*.

CHEESLIP-BAG, that in which housewives prepare and keep their runnet for making cheese. See *RUNNET*.

CHEIRANTHUS, in botany, a genus of plants whose flower consists of four cruciform petals, with six subulated parallel stamina. The fruit is a long compressed bilocular pod, opening with two valves, and filled with compressed seeds. This genus of

plants comprehends the wall-flower, stock-gill-flower, and damas violet. See the articles *WALL-FLOWER*, *STOCK*, &c.

CHELIDONIUM. See the article *CELAN-DINE*.

CHELONE, in botany, a genus of plants producing ringent monopetalous flowers. The tube of the corolla is cylindric, and very short; the mouth is inflated, oblong, convex above, and plane below; the upper lip is obtuse, and emarginated; the lower is almost equal with the higher, lightly cut in three segments. The fruit is an ovate bilocular capsule, and contains many flat roundish seeds, covered with a membranaceous margin.

Botanists enumerate three species of this genus, which are all natives of North America.

CHEMA, or **CHEME**, in antiquity, a measure, among the ancient physicians, containing two spoonfuls: it was the fifth part of the cyathus or cup: full of oil, it weighed two drams, and seventeen grains.

CHEMIN DES RONLES, in fortification, a space between the rampart and low parapet under it, for the rounds to go about the same.

CHEMISE, in fortification, the wall with which a bastion, or any other bulwark of earth, is lined for its greater support and strength: or it is the solidity of the wall from the talus to the stone-row.

Fire CHEMISE, a piece of linen-cloth, steeped in a composition of oil of petrol, camphor, and other combustible matters, used at sea, to set fire to an enemy's vessel.

CHEMICAL Laboratory, or *Elaboratory*, the place where chemical processes are performed.

CHEMISTRY, *χημια*, is an art that teaches us how to perform certain physical operations, by which bodies that are discernible by the senses, or that may be rendered so, and that are capable of being contained in vessels, may, by suitable instruments, be so changed, that particular determined effects may be thence produced, and the causes of these effects understood by the effects themselves, to the manifest improvement of various arts.

CHENOPODIUM, in botany, a genus of plants whose flower is apetalous, and contains a permanent concave pentaphyllous calix, with five subulated filaments, topped with roundish double antheræ. The cup supplies the place of a pericarpium, and contains an orbicular depressed seed. There are several species in this genus, one of which is called *Botrys* or Jerusalem oak. This plant grows naturally in many parts of America: it has a small white root, from which arises several stalks: these are round, stiff, erect, hairy, and furnished with many leaves of a light green, and somewhat like those of the oak: the flowers come out from the wings of the leaves, on the upper part of the branches, in loose spikes; these appear in July, and the seeds ripen in September. The whole plant has a strong but not disagreeable

ble smell, and the taste is subacid, aromatic, and refinous.

This plant is propagated by sowing its seeds when ripe, which is in autumn. It is reckoned to be good against cholics that proceed from wind; but in the present medical practice is not much used.

CHEQ, or **CHERIF**, the prince of Mecca, who is, as it were, high-priest of the law, and sovereign pontiff of all the Mahometans, of whatsoever sect or country they be. See **CALIPH**.

CHEREM, the Jewish antiquity, the second and greater sort of excommunication among the Jews.

CHERLERIA, in botany, a genus of decandrious plants, whose flower is apetalous; but contains five very small, roundish, emarginated nectariums, placed in a circular direction, with ten subulated filaments, topped with simple antheræ. The fruit is an ovated, trilocular capsule with three valves, containing two reniform seeds.

CHEERY-TREE, *Cerasus*, in botany, the name of a well known genus of trees, the flower of which is roseaceous, or composed of five roundish concave petals, arranged in a circular form. When the flower is decayed, the germen becomes a roundish or heart-shaped fleshy fruit, containing a roundish stone.

This genus is classed with the *prunus* or plumb, by Linnæus, but as they differ so much in the fruit, and are generally understood to be a distinct genera, it was therefore in this work thought necessary to keep them separate.

The cherry-tree, it is said, is a native of Pontus, a province of Asia Minor, from whence it was brought into Italy by Lucullus, the Roman, Anno Rom. 680; and about one hundred years after was introduced into England, where there are various sorts cultivated at present, such as the Flemish-cherry, Kentish-cherry, May-duke, arch-duke, red-heart, white-heart, black-heart, amber-heart, ox-heart, bleeding heart, carnation, morello, and some others.

The several sorts of cherries are propagated by budding or grafting the different kinds into stocks of the black or wild red cherries, they being supposed to be of longer duration than the garden sorts.

Cherry-trees are raised in great quantities in the nursery gardens, both standards, and dwarfs: the standards for planting orchards, particularly in Kent, where there are large plantations. The usual distance allowed for their standing is about forty feet each way. These standard trees should be planted in a situation defended as much as possible from the east and western winds; the one being likely to destroy their blossoms in the spring, and the other by its violence is very apt to break their tender branches: this occasions their gumming, and is very prejudicial to them. The sorts best approved of for an orchard are the Kentish, Flemish, duke, and common red cherry.

Cherry-trees may also be planted against walls in any exposure: the May-duke being generally planted against a south aspect wall, though it is not amiss to have some against a north wall, which will continue their season the longer; and the same may be done with the other sorts. The morello cherry is generally planted against walls fronting the north.

This fruit is commonly used in preserving: yet where they are planted to a better aspect, and suffered to hang on the trees till they are thoroughly ripe, they are not a bad fruit for the table; for by long hanging it loses most of its acidity or sourness.

The less cherries are pruned, the better they like it; but, however, where weak or luxuriant branches happen, they must be governed by the knife. When cherry-trees take to bearing very early, and grow but little, it is best to pull off most of the bloom, and shorten the branches, which will cause the tree to shoot with fresh vigour.

The black-cherry is supposed to be a native of England, it being frequently found in the woods, it grows large; and the timber is used by turners and other artificers in wood. From this sort the black-coroon-cherry is supposed to have been produced.

Cherry-trees thrive best in a dry hazely loam. In a gravelly soil they are very subject to blights, and seldom stand long good.

The Kentish-cherries are a very wholesome fruit, and grateful to the stomach; but the black only are used in medicine: they are prescribed in all diseases of the head and nerves; and by some are also accounted diuretic, especially the water distilled from them.

CHEERY with double flowers, a species of the former. It is propagated for the beauty of its flowers, which are extremely fine. These are produced in large bunches, which makes it one of the most beautiful which come out in the spring.

CHEERY-BARBADOES. See **MALPIGHIA**.

CHEERY-CORNELIAN. See **CORNUS**.

CHEERY-WINTER. See **ALKENENGI**.

CHERT, among miners, denotes a kind of flinty stone, found in thin strata in quarries of lime-stone.

CHERUB, or **CHERUBIN**, a celestial spirit, which in the hierarchy is placed next to the seraphim. See **HIERARCHY**.

CHESNUT-TREE, the English name of the castanea of botanists. See the article **CASTANEA**.

CHEST, in commerce, a kind of measure, containing an uncertain quantity of several commodities.

A chest of sugar, v. g. contains from ten to fifteen hundred weight; a chest of glass, from two hundred to three hundred feet; of Castile-soap, from two and an half to three hundred weight; of indigo, from one and an half to two hundred weight, five score and twelve pounds to the hundred.

CHEST, in anatomy, the breast, or that part of the body which contains the heart and lungs. See the article **BREAST**.

CHESSTREE, in naval affairs, a piece of wood which stands up and down edgeways, bolted to the ships side: there is a large hole in it, through which the rope, called the tack, is passed, which is fastened to the clue or lower corner of the main-fail; and when the clue of the sail comes down to the ches-tree, the tack is said to be aboard. *Shipwreck*, p. 51. in the *Notes*.

CHEVAGE, or **CHIEFAGE**, a tribute of a certain sum of money, formerly paid by such as held lands in villinage to their lords, by way of acknowledgement, being a kind of poll, or head-money.

CLEVALER, in the manege, is said of a horse when in passing upon a walk or trot, his off fore-leg crosses or overlaps the near fore-leg every second motion.

CHEVALIER, in a general sense, signifies a knight, or horseman: but

CHEVALIER, in heraldry, signifies any cavalier, or horseman, armed at all points, by the Romans called *cetaphractus eques*; now out of use, and only to be seen in coat-armour.

CHEVAUX DE FRISE, in fortification, a large joist or piece of timber, about a foot in diameter, and ten or twelve in length; into the sides whereof are driven a great number of wooden pins, about six feet long, armed with iron points, and crossing one another.

The chief use of the chevaux de frise, is to stop up breaches, or to secure the avenues of a camp, from the inroads both of horse and foot. It is sometimes also mounted on wheels, with artificial fires, to roll down in an assault.

CHEVRETTE, in the art of war, an engine for raising of guns or mortars into their carriages.

It is made of two pieces of wood, about four feet long, standing upright upon a third square piece: the upright pieces are about a foot asunder, and pierced with holes exactly opposite to each other, having an iron bolt, which being put through these holes higher or lower, at pleasure, serves with a hand-spike, which takes its poise over this bolt, to raise any thing by force.

CHEVRON, or **CHEVERON**, in heraldry, one of the honourable ordinaries of a shield, representing two rafters of an house, joined together as they ought to stand: it was anciently the form of the priestesses head attire: some say it is a symbol of protection; others, of constancy; others, that it represents knights spears, &c.

Per Chevron, in heraldry, is when the field is divided only by two single lines, rising from the two base points, and meeting in the point above, as the chevron does.

CHEVRONED, is when the coat is filled with

an equal number of chevrons, of colour and metal.

CHEVRONEL, a diminutive of chevron, and as such only containing half a chevron.

CHEVRONNE, or **CHEVRONNY**, signifies the dividing of the shield several times chevron-wise.

CHIAOUS, a word in the original Turkish signifying envoys, are officers to the number of five or six hundred in the grand signior's court, under the command of a chiaous bashi. They frequently meet in the grand vizier's palace, that they may be in readiness to execute his orders, and carry his dispatches into all the provinces of the empire. The chiaous bashi assists at the divan, and introduces those who have business there.

CHIARO-SCURO, among painters. See the article **CLARO-OSCURO**.

CHIAUSI, in the Turkish affairs, officers otherwise called mutes, employed in executing persons of distinction; the orders for doing of which are sent them by the grand signior, wrapped up in a black cloth.

CHICANE, or **CHICANRY**, in law, an abuse of judiciary proceeding, tending to delay the cause, to puzzle the judge, or impose upon the parties.

CHICANE, in the schools, is applied to vain sophisms, distinctions, and subtleties, which protract disputes and obscure the truth.

CHICHES, or **CHICH-PEASE**, the same with the cicer of botanists. See **CICER**.

CHICK-WEED, *Afine*, in botany. See the article **ALSINE**.

CHIEF, a term signifying the head or principal part of a thing or person. Thus we say, the chief of a family, &c.

CHIEF, in heraldry, is that which takes up all the upper-part of the escutcheon from side to side, and represents a man's head.

In **CHIEF**, imports something borne in the chief part or top of the escutcheon.

CHIEF-LORD, the feudal lord, or lord of an honour on whom others depend.

CHILBLAINS, in medicine, the same with what is otherwise called *perniones*. See the article **PERNIO**.

CHILD, a term of relation to parent.

CHILD-BED, } See **DELIVERY**.

CHILD-BIRTH, }

CHILDERMAS-DAY, or **INNOCENT'S-DAY**, an anniversary held by the church, on the 28th of December, in commemoration of the children at Bethlehem, massacred by order of Herod.

CHILIAD, denotes a thousand of any things, ranged in several divisions, each whereof contains that number. Thus the tables of logarithms are so called, because they were at first divided into thousands.

CHILIARCHA, or **CHILIARCHUS**, in antiquity,

ty, a military officer who had the command of a thousand men.

CHILIASTS, in church history, the same with the millenarians. See the article **MILLENA-RIANS**.

CHIMERA, or **CHIMÆRA**, a fabulous monster which the poets feign to have the head of a lion, the body of a goat, and the tail of a dragon; and add, that this odd beast was killed by Bellerophon.

CHIMES of a Clock, a kind of periodical music, produced at equal intervals of time, by means of a particular apparatus added to a clock.

In order to calculate numbers for the chimes, and adapt the chime-barrel, it must be observed, that the barrel must turn round in the same time that the tune it is to play require in finging. As for the chime-barrel, it may be made up of certain bars that run athwart it, with a convenient number of holes punched in them to put in the pins that are to draw each hammer; and these pins, in order to play the time of the tune rightly, must stand upright, or hang down from the bar, some more, some less. To place the pins rightly, you may proceed by the way of changes on bells, viz. 1, 2, 3, 4; or rather make use of the musical notes. Observe what is the compass of your tune, and divide the barrel accordingly from end to end.

CHIMNEY, in architecture, a particular part of a house, where the fire is made, having a tube or funnel to carry away the smoke.

The parts of a chimney are the jambs, or sides, coming out perpendicularly, sometimes circularly, &c. from the back; the mantle-tree which rests on the jambs; the tube, or funnel, which conveys away the smoke; the chimney-piece, or moulding, which is on the fore-side of the jambs, over the mantle-tree, and the hearth, or fire-place.

CHIMNEY JAMBS, the sides of a chimney, sometimes standing out perpendicularly, sometimes circularly, from the back, on the extremities whereof the mantle-tree rests.

CHIMNEY-MONEY, or **HEARTH-MONEY**, a tax imposed by statute 24 Car. II. expressing that every fire-hearth and stove of every dwelling or other house within England and Wales, except such as pay not to church and poor, shall be chargeable with two shillings per annum, payable at Michaelmas and Lady-day, to the king and his heirs. This tax being much complained of, as burdensome to the people, has been abolished, and instead of it the window-tax was granted.

CHIMNEY-PIECE, a composition of certain mouldings of wood or stone, standing on the fore-side of the jambs, and coming over the mantle-tree.

CHINA-CHINA, in pharmacy, the same with quinquina. See **QUINQUINA**.

CHINA ROOT, in the materia medica, is the

name of a drug, of which there are two kinds, oriental and occidental. The two plants differ little or nothing in the leaves, flowers, or seeds, but considerably in the root, and remarkably in the time of flowering; the Chinese blowing only in June and July, whilst the American produces flowers successively almost all the year.

Decoctions of this root drank freely, are said to promote perspiration and urine, and have been greatly commended in the venereal disease: they do not appear, however, to have any considerable virtue.

The occidental sort which grows naturally about Carthage in Spanish America, is a species of the smilax; to which article we refer the reader for its general characters.

CHINA-ROSE. See the article **HIBISUS**.

CHINA-WARE, or **PORCELAIN**, a kind of ware well known in most parts of the world. It is formed of an artificial substance of a nature betwixt earthen-ware and glass. It resists fusion in the fire, when perfect, equally with the first; and bears, in like manner, a sudden change with regard to heat and cold; but at the same time has, to a certain degree, the transparency, and entirely the close and even texture of the latter. The principle on which the substance of China is formed is as follows.

There are some kinds of earth, which being exposed to a strong heat, will, after some time, fuse and melt, and acquire the nature of glass; while there are others that, on the contrary, resist entirely the action of heat, and remain unaltered by it, at least with respect to that degree which can be applied by means of furnaces, or such artificial fires; the first of these kinds are called vitrescent earths, the others apyrous. Now these two kinds being mixed together, in due proportion, they so operate on each other, that a matter, endued with the properties above enumerated, is consequently produced: for the vitrescent earth, though it is prevented by the other from liquifying, so as to become fluid, yet melts to such a degree, as to make the parts of the whole cohere and gain a semi-transparency, while the other affords a body, which, not having any propensity to melt, hinders a greater liquefaction of the whole, by absorbing the fluid formed by the other; and gives, consequently, a proper rigidity or stiffness to the whole mass when hot, and at the same time prevents its gaining, when become cold, that vitreous grain or texture which would render it more transparent, as likewise brittle, and apt to crack or fly on any sudden change with regard to heat or cold.

The original kind of this ware manufactured in China and Japan, was accordingly formed by a composition of two earths: the one vitrescible, which is called by the Chinese petunse; the other apyrous, or resisting the action of heat, so as not to.

to suffer itself to be fused, or melted by the heat of a furnace, at least without the addition of some very powerful flux, and is called kaolin.

The more perfect imitations of the China ware in Europe have been, in like manner, by the commixture of two kinds of earth. But others, where the true composition has not been understood, or the proper materials were not to be procured, have been formed of matter, prepared by mixing with the earths some vitreous or fluxing substances, not being duly adapted to the resistance of the earth, the wares for the most part, (though some of them have been very white, and of a good confidence while in a clayey state for working, and capable of sustaining the heat of the furnace) have yet not been able to bear hot water, when suddenly poured upon them, while they are cold, without cracking or suffering a separation of their parts.

The qualities of China ware, when perfectly good, are, to be very white and tenacious, so as not only to bear violence without breaking, and strike fire with the steel as flint; but, as is said before, to suffer boiling water to be poured on it, while it is itself in a cold state, without being broken or cracked: to have a semi-transparent appearance; to break without shewing any grain in the divided parts, but seeming to have in them the even texture of glass; to shine on the exterior surface, as if a bright polish had been given to it: to be completely fit, while the composition is in the state of a moist paste, before it be dried or baked, to be modelled or cast with the greatest nicety and minuteness, retaining the figure, though wrought into the most thin and slender parts; to dry afterwards without warping; and to undergo at last the baking or burning, without any separation of the parts or flawing. If the composition, or the ware formed of it, be deficient in any of these particulars, they are so far faulty: and by examining any pieces of China with regard to those particulars, which relate to the finished ware, the comparative or absolute goodness may be easily distinguished.

The baking or burning China ware is performed much in the same manner, as is practised by the potters for earthen-ware; except that it is done with more care; and that some expedients are used for defending the pieces from the injury of the smoke or dust of the furnace, which would deprave the colour, or infect the surface with specks.

The glazing the ware of this kind is a very important part of the manufacture of it; and has been generally found the most difficult to be performed. It is done by spreading some soft glass powdered, or some fluxing composition, (either mixed with part of the matter, of which the ware itself is formed, or in some cases without) on the surface of the pieces; and melting it there, so as when cold, to make an entire covering with the smoothness and shining appearance of glass.

The painting and gilding China ware is much the same as in the case of enamel, except in some particulars; as not only the same compositions for colours serve equally well for both, but the manner of burning or fusing them is also alike, allowing for the difference of the figures of the pieces, and the number of them generally required to be burnt together. On this part of the manufacture, the value of the ware in general mostly depends, tho' it is indeed, properly considered, not a part of the art of making China-ware, but an auxiliary art employed only for the giving additional ornaments to it, being in fact only enamel painting applied to this purpose.

CHIN-COUGH, a convulsive kind of cough, which children are chiefly subject to, proceeding from a tough, viscid, and acid matter, lodged in the coats of the stomach, which when they vomit, they are easy for a time.

Sometimes this disorder proceeds from a more dangerous cause, which is a certain salt communicated to tender bodies by means of the air, which coagulates the lymph, and, which growing sharp and stagnating, affects the larynx.

In the cure of this cough, particular care should be had to the stomach; and without a vomit the cure can hardly be effected. Spermaceti in broth is of excellent use: but by bleedings and repeated purges this cough may be cured, without other means; yet the milder cathartics ought here to take place. Drinks and liquid aliments should also be taken in less quantity than usual.

CHINE, in the manege, the same with a horse's backbone.

CHINESE, something belonging to the empire of China, or its inhabitants.

CHIONANTHUS, in botany, a shrub which grows by the side of rivulets in South-Carolina, to about the height of nine or ten feet, the leaves of which are about the size of the laurel, but much thinner in substance. The flowers are monopetalous, the tube of which is very short and spreading; the upper part of which is cut into four very long segments, which are erect, acute, of a linear figure, and somewhat uneven: in the tube of the petal are inserted two short filaments, terminated with erect cordated antheræ; the fruit is an unilocular roundish black berry, containing a striated hard seed. These come out in May, hanging in long bunches, and of a pure white, from which the inhabitants give it the appellation of snow-drop-tree; and from the flowers being cut into narrow segments, it is called by some the fringe-tree.

This plant is propagated here by sowing the seeds. For the first two or three winters they require shelter; afterward they will bear the weather tolerably well.

CHIRAGRA, in medicine, a term used to denote the gout in the hand or wrist. See the article **GOUT**.
CHIRO-

CHIROGRAPH, *Chirographum*, in the time of the Saxons, signified any public instrument of gift or conveyance, attested by the subscription and crosses of witnesses.

CHIROGRAPH was also anciently used for a fine: the manner of engrossing the fines, and cutting the parchment in two pieces, is still retained in the chirographer's office.

CHIROMANCY, *χειρομαντεία*, a species of divination, drawn from the different lines and lineaments of a person's hand; by which means, it is pretended, the inclinations may be discovered.

CHIRONIA, in botany, a genus of plants; the corolla is formed of a single petal, and is equal; the tube is roundish, and of the size of the cup; the limb is divided into five equal oval segments, and patent; the fruit is of an oval figure, and contains two cells; the seeds are numerous and small.

CHIRONOMY, *Chironomia*, in antiquity, the art of representing any past transaction by the gestures of the body, more especially by the motions of the hands. This made a part of a liberal education; it had the approbation of Socrates, and was ranked by Plato among the political virtues.

CHIROTONY, *Chirotonia*, among ecclesiastical writers, denotes the imposition of hands used in conferring priestly orders. See the article **ORDER**.

CHIRURGERY, or **SURGERY**, is that part of medicine, which is employed in manual operations.

The word is formed from the Greek, *χειρ*, the hand, and *εργον*, work.

Chirurgery is undoubtedly very ancient, but its inventor is very uncertain. Some attribute it to Apis, king of Egypt, though, perhaps, on no good foundation. But, be that as it will, it is certain that during the first ages it was nearly the sole medicine, and consequently it preceded physic in point of time. In the days of Hippocrates, surgery was so connected with medicine, that the former was scarce distinguished from the latter by any peculiar and discriminating name: and that Hippocrates himself assisted the sick by manual operation, is a fact which cannot be called in question. During these last forty years, surgery has been cultivated with very great success. M. le Dran has furnished us with instructions which will inform the most skilful practitioners. M. de la Faye, the ingenious commentator on Dionis, has likewise given us, in his notes, not only what his own experience and reflections have suggested, but also, as he says, the opinions and observations of the greatest surgeons at Paris; and indeed the frequent mention he makes of Mess. Morand, Petit, de la Peyronie, and others, are sufficient proofs that his comments are an exact representation of the present state of surgery in France. M. Garengnot's treatise on the operations of surgery lies under the disadvantage of having been published some years since, and before many of those improvements were made, which are now

universally known: it, however, contains several cases and remarks well worth the attention of a studious reader. Heister's surgery is in every person's hands; and the character of Heister is so well established, that any account of that work is needless. Nor need we mention the treatise of surgery, and critical enquiry, of the ingenious Mr. Sharp, since the name of the author is abundantly sufficient.

If the reader desires a more particular account of chirurgical authors, we refer him to Heister's Surgery, where he will find a very large catalogue of them.

CHISLEY-Land, in agriculture, a soil of a middle nature, between sandy and clayey land, with a large admixture of pebbles.

CHISSEL, an instrument much used in carpentry, masonry, joinery, sculpture, &c. and distinguished according to the breadth of the blade into half-inch chisels, quarter-inch chisels, &c. They have also different names, according to the different uses to which they are applied; as, 1. The former, used by carpenters, &c. just after the work is scribed: it is struck with a mallet. 2. The paring-chisel, which is used in paring off the irregularities made by the former: this is pressed by the workman's shoulder. 3. The skew-former cleanses acute angles with the point of its narrow edge. 4. The mortice-chisel, used in cutting deep square holes in wood, for mortices: it is narrow, but thick and strong, to endure hard blows. 5. Socket-chisels, having their Shank made with a hollow socket at top, to receive a strong wooden sprig fitted into it with a shoulder. 6. Ripping-chisel, having a blunt edge, with no basil, used in tearing two pieces of wood asunder. And, 7. The gouge. See the article **GOUGE**.

CHITUA, in the materia medica, a kind of lignum aloes, of a reddish colour. See the article **LIGNUM-ALOES**.

CHIVALRY, in law, is a tenure of service, whereby the tenant is bound to perform some noble or military office to his lord; and is either regal, when held only of the king; or common, such as may be held of a common person as well as the king: the former is properly called **serjeantry**, and the latter **escuage**. See the articles **SERJEANTRY** and **ESCUAGE**.

A statute of Charles II. abolishes all tenures by chivalry, in capite, &c. and ordains that all tenures shall be construed to be free and common soccage.

CHIVES, or **CRIVES**, a very small sort of onion. These never produce any bulbs; and seldom grow above six inches high in the blade, which is small and slender.

They are increased by parting the roots; and were formerly much used in spring-sallads; but of late years have been little noticed.

CHLORITES, in natural history, a kind of green

green jasper; but almost as pellucid as the coarser emeralds. See JASPER.

CHLOROSIS, in medicine, a disease commonly called the green sickness, incident to girls, maids, widows, and even wives, whose husbands are deficient.

Various are the symptoms of this disorder, as a feverish habit of body, vomiting, difficulty of breathing, and longing for unnatural foods.

As to the cure, Astruc recommends borax, mineral waters, electuaries made of preparations of steel, the martial flowers, &c. asafetida, aloes and myrrh, emollient baths, frequent evacuations, and exercise; but above all, matrimony.

CHOCOLATE, in commerce, a kind of paste, or cake, prepared of certain drugs, the basis of which is the cacao nut.

CHOIR, that part of the church or cathedral where choiristers sing divine service: it is separated from the chancel, where the communion is celebrated; and also from the nave of the church, where the people are placed: the patron is said to be obliged to repair the choir of the church. It was in the time of Constantine that the choir was separated from the nave. In the twelfth century, they began to inclose it with walls; but the ancient balustrades have been since restored, out of a view to the beauty of architecture.

CHOIR, in nunneries, is a large hall adjoining to the body of the church, separated by a grate, where the nuns sing the office.

CHOLAGOGUES, medicines which purge the bile.

Of this kind are manna, cassia, roses, fena, rhubarb, aloes, jalap, scammony, &c. There is some reason to think that antimonial medicines act more powerfully on the bile than any other remedies.

CHOLEDOCHUS, in anatomy, is a common epithet for the gall-bladder, the hepatic vessels, and the common gall duct, which communicates with the duodenum.

CHOLER, or **BILE**. See **BILE**.

CHOLERA-MORBUS, in medicine, the same with bilious fever. See **BILIOUS**.

CHOMER, **HOMER**, or **OMER**, the same with corus. See the article **CORUS**.

CHONDRILLA, in botany, a plant which grows naturally in France, Switzerland, and Germany, the roots of which run deep into the ground, and spread out with thick fibres on every side, each of which, when broke, will produce a fresh plant, which renders it in those parts (where it is considered as a weed) very difficult to be eradicated. From the root arise a number of slender stalks, which at their bottom are furnished with oblong leaves; but those above are narrow and entire. The flower is compound, imbricated, and uniform: the proper one monopetalous, ligulated, linear, truncated, and four or five times dentated. There is no pericarpium.

The cup is of a cylindrical figure, containing solitary, ovated, compressed seeds, crowned with down.

It flowers in May, and the seeds are ripe in September.

CHONDROGLOSSUM, in anatomy, the name of a pair of muscles arising from the cartilaginous process of the os hyoides, and meeting in the base of the tongue, where they are inserted: this pair is not found in all subjects.

CHOPIN, or **CHOPINE**, a liquid measure, used both in Scotland and France, and equal to half their pint. See the articles **PINT** and **MEASURE**.

CHORD, in geometry, is a right-line connecting the extremities of any arch of a circle.

Line of CHORDS is the chords of a circle projected on a right-line. See **Plane SCALE**.

CHORDS, in music, are the strings, or lines, by whose vibrations the sensation of sound is excited, and by whose divisions the several degrees of tune are determined.

They are called cords, or chords, from the Greek, χορδή, a name which the physicians give to the intestines; in regard the strings of musical instruments are ordinarily made of guts, though others are made of brass or iron wire, as those of spinnets, harpsichords, &c.

Chords of gold wire, in harpsichords, yield a sound almost twice as strong as those of brass: chords or strings of steel yield a feebleer sound than those of brass, as being less heavy, and less ductile.

The tone of a sound depends on the time or duration of the stroke made on the drum of the ear, by a wave or pulse of air; for as that is longer or shorter, the tone will be more grave or acute: and since all pulses move equally swift, the duration of a stroke will be proportional to the interval between two successive pulses; and consequently a sound is more or less grave or acute, in proportion to the length of that interval.

Hence it follows, that all the sounds, from the loudest to the lowest, which are excited by the vibrations of the same body, are of one tone. It likewise follows, that all those bodies, whose parts perform their vibrations in the same or equal times, have the same tone: also those bodies which vibrate slowest have the gravest and deepest tone, as those which vibrate quickest have the sharpest or shrillest tone.

CHORD, *Corda*, in anatomy, a little nerve composed by a combination of ramuli of the fifth and seventh pairs, and extended in the manner of a chord, under the membrane of the drum of the ear. See the article **TYMPANUM**.

CHORDEE, in medicine and surgery, a symptom attending a gonorrhoea, consisting in a violent pain under the frenum, and along the duct of the urethra, during the erection of the penis, which is incurvated.

incurvated downwards. These erections are frequent and involuntary.

CHOREA SANCTI VITI, **ST. VITUS'S DANCE**, in medicine. See the article *VITUS'S Dance*.

CHOREPISCOPUS, or **COUNTRY-BISHOP**, an assistant to a bishop, first introduced into the church when the dioceses became enlarged by the conversion of the pagans in the country and villages at a distance from the mother-church.

CHOREPISCOPUS is also the name of a dignity in some cathedrals in Germany, signifying the same with chori-episcopus, or bishop of the choir. The first chanter in the church of Cologne is called chori-episcopus.

CHOREUS, in ancient poetry, the same with trocheus or trochee. See the article *TROCHEE*.

CHORIAMBUS, in ancient poetry, a foot consisting of four syllables, whereof the first and last are long, and the two middle ones are short; or, which is the same thing, it is made up of a trocheus and iambus: such is the word *nobilitas*.

CHORION, in anatomy, the exterior membrane which invests the foetus in the uterus: it is thick, spongy, villous, and furnished with a vast apparatus of blood-vessels. It is contiguous to the uterus, and is separable into membranes or parts.

CHOROBATA, or **CHOROBATES**, a kind of water-level among the ancients, of the figure of the letter T, according to Vitruvius's description.

CHOROGRAPHY, the art of making a map of some country or province.

Chorography differs from geography, as the description of a particular country does from that of the whole earth; and from topography, as the description of a country differs from that of a town or district. See the articles *GEOGRAPHY* and *TOPOGRAPHY*.

CHOROIDES, in anatomy, an epithet of several membranes, which on account of the multitude of the blood-vessels resemble the chorion. See *CHORION*.

CHOROIDES denotes the coat of the eye placed immediately under the sclerotica, the inferior lamella of which is called *tunica Ruchiana*: it is very full of vessels, and coloured black.

Mr. Le Cat, in his description of the parts of the eye, maintains Mariot's opinion of the choroid coat, and not the retina, being the immediate organ of vision. The retina, according to him, is to the choroid what the epidermis is to the skin.

CHOROIDES is used for a portion of the pia mater. See the article *Pia MATER*.

Plexus CHOROIDES is a convolution of the membranes of the brain, consisting of an assemblage of veins and arteries.

CHORO-FAVORITO, in the Italian music, a chorus in which are employed the best voices and

instruments to sing the recitatives, play the ritornellos, &c. It is otherwise called the little chorus, or *choro recitante*.

CHORUS, in dramatic poetry, one or more persons present on the stage during the representation, and supposed to be by-standers, without any share in the action.

CHORUS, in music, is when, at certain periods of a song, the whole company are to join the singers in repeating certain couplets or verses.

The word chorus is often placed in Italian music, instead of *tutti*, or *da capella*, which mean the grand chorus. When after chorus we meet with 1^o, or *primo*, we must understand that it is to be played in the first chorus; if 2^o, *Il^o*, or *secondo*, in the second; and, consequently, that the composition is for eight voices or different parts.

CHOSE, in the common law, is used with various epithets: as,

CHOSE in Action is an incorporeal thing, and only a right, as an annuity, bond, covenant, &c. and generally all causes of suit, for any duty or wrong, are accounted choses in action.

Choses in action may be also called choses in suspense, as having no real existence, and not being properly in our possession.

CHOSE LOCAL is any thing that is annexed to a place, such as a mill, &c.

CHOSE TRANSITORY, something moveable, and which may be taken away, or carried from place to place.

CHOUAN, in commerce, the Levant name for the seed of a species of *santolina*, known among us by that of carmine seed, from its being often used in the preparation of that drug.

CHOUGH, or **CORNISH CHOUGH**, in ornithology, a species of corvus, otherwise called *coracias*. See the articles *CORVUS* and *CORACIAS*.

CHRISM, *χρῖσμα*, oil consecrated by the bishop, and used in the Romish and Greek churches in the administration of baptism, confirmation, ordination, and extreme unction.

CHRISM-PENCE, a tribute anciently paid to the bishop by the parish clergy for their chrism, consecrated at Easter for the ensuing year: this was afterwards condemned as simoniacal.

CHRIST, *Χριστος*, an appellation usually given to our Saviour, answering exactly to the Hebrew *Messiah*, and signifying one that is anointed. See *MESSIAH*.

Order of CHRIST, a military order, founded by Dionysius I. king of Portugal, to animate his nobles against the Moors.

The arms of this order are gules, a patriarchal cross, charged with another cross argent: they had their residence at first at Castromarin, afterwards they removed to the city of Thomar, as being

nearer to the Moors of Andalusia and Estremadura.

CHRIST is also the name of a military order in Livonia, instituted in 1205, by Albert bishop of Riga. The end of this institution was to defend the new Christians, who were converted every day in Livonia, but were persecuted by the heathens. They wore on their cloaks a sword with a cross over it, whence they were also denominated Brothers of the Sword.

CHRIST-THORN, in botany, a name given to the *paliurus*, a species of *rhamnus*. See the article **RHAMNUS**.

CHRISTENING, denotes the same with baptism. See the article **BAPTISM**.

CHRISTIAN, in a general sense, something belonging to Christ.

CHRISTIAN RELIGION, that instituted by Jesus Christ.

CHRISTIANS, those who profess to believe and practise the Christian religion, and are baptized in the name of Jesus Christ.

CHRISTIANS of St. John, a sect of Christians very numerous in Balfora, and the neighbouring towns: they formerly inhabited along the river Jordan, where St. John baptized, and it was from thence they had their name.

CHRISTIANS of St. Thomas, a sort of Christians in a peninsula of India, on this side of the gulf: they inhabit chiefly at Cranganor, and the neighbouring country: these admit of no images, and receive only the cross, to which they pay great veneration.

CHRISTMAS, a festival of the Christian church, observed on the 25th of December, in memory of the nativity of Jesus Christ.

CHRISTMAS-ROSE, in botany, a name sometimes given to a species of black hellebore. See the article **HELLEBORE**.

CHRISTOLYTE, in church-history, a sect of Christian heretics, who maintained that Christ descended into hell, body and soul, and that he left both there, ascending into heaven with his divinity alone.

CHRISTOMACHI, an appellation given to all heretics, who deny Christ's divinity, or maintain heterodox opinions concerning his incarnation.

CHRITOPHORIANA, in botany. See **ACTEA**.

CHROMATIC, in the ancient music, the second of the three kinds into which the consonant intervals were subdivided into their concinnous parts. The other two kinds are enharmonic and diatonic. See the articles **ENHARMONIC**, &c.

CHROMATIC, in painting, a term used to signify the colouring, which makes the third part in the art of painting.

CHRONIC, or **CHRONICAL**, among physicians, an appellation given to diseases that continue

a long time, in contradistinction to those that soon terminate, and are called acute.

CHRONICLE, *χρονης*, in matters of literature, a species or kind of history, disposed according to the order of time, and agreeing in most respects with annals. See the article **ANNALS**.

Books of CHRONICLES, in the canon of Scripture, two sacred books; called by the Greeks, *paralipomena*, *παροληπόμενα*; that is, remains, additions, or supplements, as containing many circumstances omitted in the other historical books.

CHRONOGRAM, *χρονογραμμά*, a species of false wit, consisting in this, that a certain date or epocha is expressed by numeral letters of one or more verses.

CHRONOLOGY, as it is commonly accepted, is the arithmetical computation of time for historical uses, that thereby the beginnings and endings of princes reigns, the revolutions of empires and kingdoms, battles, sieges, or any other memorable events or actions may be truly stated.

Strumius divides chronology into five distinct branches, viz. metaphysical, physical, political, historical, and ecclesiastical, according to the various relations or habitudes wherein time is considered, that is, as in itself, as connected and subjected to the affections, states, and alteration of natural things, as accommodated to civil uses, as matched with events that pass in the world, and particularly as it relates to the celebration of Easter.

To be a good chronologist, requires not only the knowledge of astronomy and geography, and consequently that of arithmetic, geometry, and trigonometry, both plain and spherical, but also close application to the ancient monuments.

Sir Isaac Newton, in order to settle the grand epocha of the Argonautic expedition, makes use of the following principles.

He observes, that Eudoxus, in his description of the sphere of the antients, placed the solstices and equinoxes in the middle of the constellations Aries, Cancer, Chétre, and Capricorn; and also that this sphere or globe was first made by Museus, and the asterisms delineated upon it by Chiron, two of the Argonauts. Now it is well known, that by the precession of the equinoxes the stars go back 50' per annum. And since, at the end of the year 1689, the equinoctial colure passing through the middle point, between the first and last star of Aries, did then cut the ecliptic in 8° 6' 44", it is evident, that the equinox had then gone back 36° 44'; therefore, as 50' is to one year, so is 36° 44' to 2645 years, which is the time since the Argonautic expedition to the beginning of the year 1690; that is, 955 years before Christ, is the æra of the Argonautic expedition.

But our great author is more particular and subtle in this affair. He finds the mean place of the colure of the equinoxes and solstices, by considering

ing the several stars they passed through among other constellations as follows, according to Eudoxus. In the back of Aries is a star of the sixth magnitude, marked γ by Bayer; in the end of the year 1689, its longitude was $8^{\circ} 38' 45''$; and the equinoctial colure passing through, according to Eudoxus, cuts the ecliptic in $8^{\circ} 58' 57''$.

In the head of Cetus are two stars of the fourth magnitude, called γ and ξ by Bayer. Eudoxus's colure, passing in the middle betwixt them, cuts the ecliptic in $8^{\circ} 6' 58' 51''$, at the end of the year 1689.

In the extreme flexure of Eridanus there was formerly a star of the fourth magnitude (of late it is referred to the breast of Cetus.) It is the only star in Eridanus, through which the colure can pass; its longitude was at the end of the year 1689 γ $25^{\circ} 22' 10''$, and the colure of the equinox passing through it cuts the ecliptic in $8^{\circ} 12' 40''$.

In the head of Perseus, rightly delineated, is a star of the fourth magnitude, called γ by Bayer; its longitude was $8^{\circ} 23' 25' 30''$, at the end of the year 1689; and the colure passing through it cuts the ecliptic in $8^{\circ} 6' 18' 57''$. Also in the right-hand of Perseus is a star of the fourth magnitude, whose longitude at the end of the year 1689, was $8^{\circ} 24' 25' 27''$, and the equinoctial colure passing through it cuts the ecliptic in $8^{\circ} 4' 56' 40''$.

Now the sum of all these	$\left\{ \begin{array}{l} 8^{\circ} 6' 58' 57'' \\ 8^{\circ} 6' 58' 51'' \\ 8^{\circ} 7' 12' 40'' \\ 8^{\circ} 6' 18' 57'' \\ 8^{\circ} 4' 56' 40'' \end{array} \right.$
five places of the colure,	
viz.	

Is = 1 2 26 05

The fifth part of which is $= 8^{\circ} 6' 29' 13''$, which is therefore the mean place in which the colure did, in the end of the year 1689, cut the ecliptic.

After a like manner he determines the mean place of the solstitial summer colure, to be $21^{\circ} 28' 46''$, which, as it is just 90° from the other, shews it to be rightly deduced. The equinoxes having then departed $1^{\circ} 6' 29''$ from the cardinal points of Chiron, shews that 2628 years have elapsed since that time, which is more correct than the former number, though less by only seventeen years. See PRECESSION.

By some other methods of a like nature, he also shews the æra of the Argonauts ought to be placed in that age of the world; and having fixed this most ancient epocha, he makes his computation, with reference thereto, in the future part of his book.

As to the authors who have written on this science, they are very numerous; among the moderns are Petavius, Vossius, Usher, Sir Isaac Newton, &c. and among the antients, Julius Africanus, Eusebius, &c. There is also an excellent Treatise of Chronology by the learned Strauchius, translated into

English by Mr. Sault, F. R. S. and an useful compend by Mr. Wells.

CHRONOMETER, a general name for any instrument used in the measuring of time; in this sense clocks, watches, dials, &c. are chronometers: though there are some other instruments peculiarly called by that name, particularly one described by Mr. Sauveur in his Principles of Acoustics, as likewise one described in Dr. Desaguliers's Experimental Philosophy; which is a kind of clock, contrived to measure small portions of time with great exactness, even to the sixteenth part of a second; which is of great use in astronomical observations, the time of the fall of bodies, the velocity of running waters, &c. But these kind of chronometers must not be depended on for any long space of time, except their pendulums be made to vibrate in a cycloid, because all clocks, which have short pendulums, are liable to err more considerably than those with long pendulums.

CHRYsalis, in natural history, a state of rest and seeming insensibility which butterflies, moths, and several other kinds of insects, must pass through before they arrive at their winged or more perfect state. See BUTTERFLY.

The first state of these animals is in the caterpillar or reptile form: then they pass into the chrysalis-state, wherein they remain immoveably fixed to one spot, and surrounded with a case or covering, which is generally of a conical figure; and, lastly, after spending the usual time in this middle state, they throw off the external case wherein they lay imprisoned, and appear in their most perfect and winged form of butterflies, or flies. See CATERPILLAR.

Through the whole course of this transformation, the animal remains the same, only surrounded with different coverings; in the caterpillar form, it is a kind of foetus, or embryo, wrapped up in several coats, the limbs of which can only be discovered by the assistance of the microscope: in the chrysalis or nymph-state, it acquires a farther degree of maturity; and then the limbs, wings, &c. become perfectly distinct; and at length it disengages itself, and becomes an inhabitant of the air, adorned with a peculiar kind of plumage: in this last state the two sexes copulate, and the female lays her eggs to be afterwards hatched into caterpillars, and to pass through the like changes with the parent-insect.

CHRYsANTHEMUM, CORN-MARIGOLD, in botany, a genus of plants, producing compound, radiated flowers, the proper hermaphrodite florets are funnel-shaped, and the female, ligulated, oblong, and tridentated; it is destitute of a pericarpium, but the immutated cup contains several solitary, oblong, naked seeds.

There are various species belonging to this genus, one of which grows very common in corn fields; another

another species, which is annual, and either with white or yellow-coloured flowers, is cultivated in gardens: these make an agreeable appearance, particularly those with double flowers; a variety of which (called the quilled chrysanthemum) is most esteemed; these may be increased by cuttings in the summer, and preserved in a green-house in winter.

CHRYSOBALANUS, in botany, a genus of icosandrious plants; the flower of which consists of five oblong, plain, patent petals, inserted in a campanulated cup.

The fruit is an ovated, large unilocular berry, inclosing an ovated nut, with five longitudinal furrows.

There are two species in this genus; but being natives of the warm parts of America, they require a hot-house for their preservation in this climate.

CHRYSOBERYL, a kind of beryl with a tincture of yellow. See **BERYL**.

CHRYSOCOMA, or **CHRYSOCOME**, goldy-tlocks, in botany, a genus of plants, the compound flower of which is tubulous, the proper one of a funnel-form, with a quinquifid limb. There is no pericarpium, but the cup scarcely immutated, contains solitary, ovato-oblong, compressed seeds, crowned with a hairy down.

CHRYSOGONUM, in botany, a genus of plants, the universal flower of which is radiated; the proper hermaphrodite one of a funnel-form, quinquidentated and erect; the female one plain, oblong, truncated, and indentated. There is no pericarpium: the immutated cup contains solitary, obovfo-cordated, quadrangular seeds in the female; the hermaphrodites prove abortive.

CHRYSOLITE, in natural history, a gem which the ancients knew under the name of the topaz; and the true chrysolite of the ancients, which had its name from its fine gold-yellow colour, is now universally called topaz by modern jewellers. See the article **TOPAZ**.

CHRYSOLITE-PASTE, a kind of glass made in imitation of natural chrysolite, by mixing two ounces of prepared chrysol with ten ounces of red-lead, adding twelve grains of crocus martis made with vinegar; and then baking the whole for twenty-four hours, or longer, in a well-luted crucible.

CHRYSOPHYLLUM, star-apple, in botany, a genus of trees which grows naturally in the West-Indies to the height of twenty or thirty-feet, dividing in'o many branches. The flowers which are monopetalous and campanulated, come out from the side of the branches, and are succeeded by large globose berries, each containing three or four compressed officious seeds.

The fruit of these trees are very rough and astringent at first, but by laying some time after they are gathered they become mellow.

The timber is used in the West-Indies for building, and for shingles to cover houses.

CHRYSOPRASUS, or **CHRYSOPRASIUS**, the tenth of the precious stones mentioned in the Revelations as forming the foundation of the heavenly Jerusalem.

The chrysoprasius is a species of prasius, of a pale but pure green colour, with an admixture of yellow. See **PRASIUS**.

CHRYSOSPLENIUM, golden saxifrage, in botany, a genus of plants, producing apetalous flowers, each of which contains a coloured permanent calyx, divided into four or five parts, in which is inserted eight or ten erect subulated stamina.

The fruit is an unilocular, two horned capsule, containing a number of very small seeds.

This genus contains two species which grow wild in many parts of England; they flower in March or April.

CHUB, or **CHUBB**, in ichthyology, the English name of a species of cyprinus, with eleven rays in the pinna ani. See the article **CYPRINUS**.

CHURCH, has different significations, according to the different subjects to which it is applied, 1. It is understood of the collective body of Christians, or all those over the face of the whole earth, who profess to believe in Christ, and acknowledge him to be the Saviour of mankind.

2. Church is applied to any particular congregation of Christians, who at one time, and in one place, associate together and concur in the participation of all the institutions of Jesus Christ, with their proper pastors and ministers.

3. Church denotes a particular sect of Christians distinguished by particular doctrines and ceremonies.

4. The word church is used to signify the body of ecclesiastics, or the clergy, in contradistinction to the laity.

5. Church is used for the place where a particular congregation or society of Christians assemble for the celebration of divine service.

CHURCH WARDENS, formerly called church-reeves, are officers chosen yearly, in Easter-week, by the minister and parishioners of every parish, to look after the church, church-yard, church-revenues, &c. also to observe the behaviour of the parishioners, in relation to such misdemeanors as appertain to the censure or jurisdiction of the ecclesiastical court.

CHURLE, **CEORLE**, or **CARL**, in the time of the Saxons, signified a tenant at will, who held land of thanes, on condition of rent and service. They were of two sorts, one like our farmers that rented the out-land estates, the other which tilled and manured the demesnes, and therefore called ploughmen.

CHYLE, in the animal economy, a milky fluid.

fluid, secreted from the aliments by means of digestion.

The principles of the chyle seem to be sulphureous; mucilaginous, saline, and aqueous. It is a kind of natural emulsion, both with regard to the colour, the ingredients, and the manner of preparation. There is this difference between the artificial and natural emulsion, that the latter is far more pure, and is prepared with much greater apparatus, not by the sudden expression of part of the liquid, but by a gentle and successive percolation.

CHYLIFICATION, the formation of the chyle, or the act whereby the food is changed into chyle.

Chylification commences by comminuting the aliment in the mouth, mixing it with saliva, and chewing it with the teeth; by these means the food is reduced into a kind of pulp, which, being received into the stomach, mixes with the juices thereof; and thus diluted, begins to ferment or putrify; and assuming a very different form from what it had before, grows either acid or rancid. Here it meets with a juice separated from the blood by the glands of that part, whose excretory ducts open into the cavity of the stomach; by the commixture of these liquors, whether of saliva, or the juice of the stomach, a proper menstruum is composed, by which the parts of the aliment are still more and more divided by its insinuating into their pores, and acquire still a greater likeness to the animal fluids, and form what is called chyme. The stomach, by means of its muscular fibres, contracting itself, gradually discharges its contents by the pylorus into the duodenum; in which gut, after a small femicircular descent, it meets with the pancreatic juice and bile; both which joining with it, renders some part of the aliment more fluid, by still disuniting the grosser parts from the more pure, and here the chylification is made perfect.

The bile, which abounds with lixivial salts, and apt to entangle with the grosser parts of the concocted aliment, stimulates the guts, and cleanses their cavities of the mucous matter separated from the blood by the glands of the guts, and lodged in their cavities; which not only moistens the inside of the guts, but defends the mouth of the lacteal vessels from being injured by alien bodies, which often pass that way.

The contents of the intestines move still on, by means of the peristaltic motion of the guts; whilst those thinner parts, fitted to the pores of the lacteal vessels, are absorbed by them: the thicker move more slowly on, and by the many stops they continually meet with by the connivent valves, all the chyle or thin parts are at length entirely absorbed; the remains, being merely excrementitious, are only fit to be protruded by stool.

In the passage through the small intestines, the finer part of the mass, which we call chyle, as has been already observed, enters the orifices of the lac-

teal vessels of the first kind, wherewith the whole mesentery is intermixed, which either alone, or together with the meseric veins, discharge themselves into the glands, at the basis of the mesentery.

Then the chyle is taken up by the lacteals of the second kind, and is conveyed into glands between the two tendons of the diaphragm, called Pecquet's Reservoir, whence it is carried to the heart by the thoracic duct and the subclavian vein: and here it first mixes with the blood, and in time becomes assimilated thereto.

CHYMISTRY, or CHEMISTRY. See the article CHEMISTRY.

CIBOULS, in botany, a small kind of onion, now much in disuse.

CICATRICULA, among natural historians, denotes a small whitish speck in the yolk of an egg, supposed to be the first rudiments of the future chick.

CICATRIX, in surgery, a little seam or elevation of callous flesh rising on the skin, and remaining there after the healing of a wound or ulcer. It is commonly called a scar.

CICELY Sweet, in botany, a plant with a perennial, long, thick, soft root, composed of many fibres of a sweet aromatic taste, from which arise many branching stalks, which grow to the height of four or five feet; these are downy and hollow. The leaves are large, and winged like those of the hemlock, but whiter; they are soft to the touch, a little downy, and have the smell of chervil. The flowers grow in umbels on the tops of the stalks, of a white colour, and a sweet aromatic scent; these appear in May or June, and are succeeded by long, angular, furrowed seeds, having the smell and taste of anniseed, and are ripe in July.

This plant is reckoned a pectoral, and the leaves being dried in the shade, and smoked like tobacco, is of great efficacy in asthmatic disorders.

It is a native of Germany, but has been long cultivated in England.

For its general characters, see the article SCANDIX, of which it is a species.

CICER, the chick-pea, in botany, an annual plant, with a slender fibrous root, from whence proceed several stalks; these are hairy, and furnished with conjugated leaves, each composed of seven or nine pair of lobes, serrated on their edges, and terminated by an odd one.

The flowers, which are papilionaceous, proceed from the side of the branches, and are like those of the pea, but smaller. These are white and stand on long foot-stalks; each hath ten stamina, and the fruit is a turgid, swelling pod, of a rhomboidal shape, containing two roundish seeds.

The seeds of this plant are accounted in some measure absterfive, and for that reason are met with in diuretic compositions in the officinal medicines: but they are very seldom found in other prescriptions.

fions. Chick pease was the provision of the ancient Hebrews, when they took the field. They parched them, and so eat them; and at this day, in Egypt, it is usual for those who undertake a long journey, to lay in a good stock of chick-pease, parched in a frying-pan.

CICHORIUM, succory, in botany, a genus of plants, producing compound, plain, uniform flowers; the proper ones are monopetalous, ligulated, truncated, and deeply quinqueidentated. The germin is situated in a cylindrical calyx, which is connivent at the top, and contains solitary, compressed seeds with acute angles.

All the sorts of succory are esteemed aperitive and diuretic, opening obstructions of the liver, and good for the jaundice; it provokes urine, and cleanses the urinary passages of slimy humours. The juice taken in large quantities, so as to keep up a gentle diarrhæa, and continued for some weeks, has been found excellent against the scurvy and other chronic disorders.

CICUTA, water-hemlock, in botany, a poisonous plant, which grows in standing waters in several parts of England; it has a branching hollow stalk, which is terminated by umbels of yellowish flowers. The whole plant greatly resembles smallage; their difference is, that the leaves of this plant are long, slender, and deeply cut, commonly into three segments, and those of smallage are cut in the same manner, but the segments are short and broad. The roots of this plant are at first hollow and green, and lined internally with a shining white matter: by age they become harder and more solid, and change their green colour to a pale yellowish: when full grown, they are as large as the fist. They have a number of fibres, like the common celery-root, especially at the bottom, by which they are fastened to the earth at the bottom of the water wherein they are commonly produced: they are often, however, loosened and carried off by the water; and too often have been taken up and eaten for celery, of which several melancholy instances have happened.

Their poisonous quality resides in an orange-yellow juice, which is distributed indeed through the whole plant, but accumulated most plentifully in the roots.

On a chemical analysis, both the leaves and roots of this plant are found to contain a large quantity of watery moisture. Four ounces of the fresh roots were reduced, by drying, to three drams and a half; from which were obtained two drams of spirituous and half a dram of watery extract; only one dram of earthy matter remaining from the whole four ounces. The leaves lost more in drying, and yielded less earth than the roots: the quantity of watery extract was two drams from four ounces: the residuum gave but half a scruple to spirit. Sixteen ounces of the leaves yielded in

expression ten ounces of juice, which, on being inspissated, left no more than a scruple of solid matter.

CILIA, the eye-lashes, in anatomy, are certain rigid hairs situated on the arch or tarsus of the eyelids, and bent in a very singular manner.

They are destined for keeping external bodies out of the eye, and for moderating the influx of light.

CILIATED Leaf, among botanical writers, one surrounded all the way with parallel filaments, somewhat like the hairs of the eye-lids, whence its name.

CILIARE, or **LIGAMENTUM CILIARE**, or **CILIARIS PROCESSUS**, in anatomy, a range of black fibres disposed circularly, having their rise in the inner part of the uvea, and terminating in the prominent part of the chrysaline humour of the eye, which they surround.

CIMA, or **SIMA**, in architecture, a member or moulding, called ogee and cymatium.

CIMOLIA TERRA, in natural history, a species of white marle, which is ponderous and friable, and makes a considerable effervescence with aquafortis.

CIMOLIA ALBA, a name given to the hard, heavy, white clay, whereof tobacco-pipes are made.

CINCHONA, in botany, a genus of plants, the flower of which is monopetalous and infundibuliform; the fruit is a roundish bilocular capsule, crowned with a cup, and opening into two parts from the base to the apex, containing several oblong, compressed, margined seeds.

This is the tree which produces the quinquina, or Peruvian bark. See the article **QUINQUINA**.

CINCTURE, in architecture, a ring or list, at the top and bottom of the shaft of a column, separating the shaft at one end from the base, and at the other from the capital.

That at the bottom is peculiarly called apophyge, as if the pillar took its flight from thence; and that at the top corolar, or collar.

CINERITIOUS, an appellation given to different substances, on account of their resembling ashes, either in colour or consistence: hence it is, that the cortical part of the brain has sometimes got this epithet. See the article **BRAIN**.

CINNABAR, in natural history, is either native or factitious. The native cinnabar is an ore of quick-silver moderately compact, very heavy, and of an elegant striated red colour. In this ore the quick-silver is blended in different proportions with sulphur. It is so rich an ore, as to be no other than mercury impregnated with a small quantity of sulphur, just enough to reduce it to that state, being commonly more than six parts of mercury to one of sulphur; and even the poorest cinnabar yields one half mercury: it is of a very bright glittering appearance, when fresh broken; and is usually found

found lodged in a bluish, indurated clay, though sometimes in a greenish talcy stone.

Falsitious CINNABAR, a mixture of mercury and sulphur sublimed; and thus reduced into a fine red glebe. The best is of a high colour, and full of fibres, like needles.

Cinnabar is likewise used by painters as a colour, and is rendered more beautiful, by grinding it with gum-water and a little saffron.

There is likewise a blue cinnabar, made by mixing two parts of sulphur with three of quicksilver and one of sal-armoniac.

CINNABAR of Antimony, a preparation of mercury, sulphur, and antimony, made by sublimation, said to be a good diaphoretic and alterative.

CINNAMON, *Cinnamomum*, the bark of a tree of the bay kind, growing in the island of Ceylon; freed from the outer green or greyish part, and cut into long slices, which curl up, in drying, into quills or canes, the form in which it is brought to us; very thin, light, of a reddish yellow colour, or pale rusty iron colour, somewhat tough in breaking, and of a fibrous texture like wood. It is frequently mixed with another bark, greatly resembling it in appearance, but much weaker in virtue, *casta lignea*: this last is distinguished by the close smooth surface which it exhibits on being broken, and by its remarkably slimy taste.

This bark is one of the most grateful of the aromatics; of a very fragrant smell, and a moderately pungent, glowing, but not fiery taste, accompanied with a considerable sweetness, and some degree of astringency. It is said, that the fine flavour resides, originally, only in the thin pellicle which lines the interior surface of the bark, and which abounds with vesicles of essential oil; the rest of the bark, while fresh, being merely subastringent, and receiving the flavour, which we find it to have, from the inner pellicle in drying. Accordingly the thinnest pieces are found to be strongest; as containing the largest proportion of this active part, and the least of the inert woody matter.

Cinnamon, infused in boiling-water in a close vessel, gives out to the fluid the greatest part of its virtue; together with a reddish brown tincture, deeper or paler, according to the proportion of cinnamon employed. Rectified and proof spirit extract its virtues more perfectly than water, and without the assistance of heat; three ounces of the powdered bark, by cold maceration for a few days, give a strong impregnation to a quart of proof spirit.

The aromatic principle of this spice is an essential oil; which, in distillation with water, rises slowly, difficultly, and renders the liquor somewhat milky: the water continues to run milky, and gratefully impregnated with the fragrance of the cinnamon, till about a gallon has been drawn off from a pound: when large quantities of the spice are submitted to

the operation at once, a small portion of the oil commonly separates and sinks to the bottom of the water; in colour gold yellow; of a delightful smell like that of cinnamon itself; and of a fiery pungency, so as not to be safely tasted or applied to the skin without dilution; for, as Boerhaave observes, it burns to a gangrenous eschar: in doses of a drop or two, diluted by the means of sugar, mucilages, &c. it is one of the most immediate cordials and restoratives, in languors, singultuses, and all debilities of the vis vitæ. If the milky distilled water be long kept, great part of the ponderous oil suspended in it, separates and subsides: some with a view to the perfection of the water, endeavour to prevent this separation, by adding a small proportion of sugar, which contributes to keep the oil dissolved: others, with a view only to the obtaining of the oil, endeavour to promote the separation, by setting the liquor in a very cold place, and perhaps by other means not commonly known. It is said, that from sixteen ounces of good cinnamon, about two drams of oil may be collected.

On distilling proof spirit from this spice, the purely spirituous part, which comes over first, proves almost flavourless, but the watery part which follows brings with it the essential oil; and this oil being dissolved by means of the spirituous portions, the liquor proves limpid. A cordial water of this kind is commonly prepared in the shops, by drawing off a gallon of proof-spirit from a pound of cinnamon. A like preparation might be obtained rather more advantageously, and free from the foreign flavour which the common proof-spirits are accompanied with, by adding to the simple water a suitable quantity of pure rectified spirit.

White CINNAMON, called also winter's bark, is the bark of a tree frequent in the island of St. Domingo, Guadalupe, &c. of a sharp biting taste like pepper. Some use it instead of nutmeg; and in medicine it is esteemed a stomachic and antiscorbutic. See *WINTERANUS Cortex*.

CINQUEFOIL, *Quinquefolium*, in botany, the same with the potentilla of Linnæus. See the article *POTENTILLA*.

Cinquefoil roots are esteemed drying, astringent, and antifebrile; and accordingly have been prescribed with success in agues and fluxes of all kinds.

CINQUE-PORTS, an appellation given to five port-towns, situated on the coast of Kent and Sussex, overagainst France, and famous in English history.

The cinque-ports are Hastings, Dover, Hithe, Romney, and Sandwich; which had large privileges granted them, on account of their former great importance, being then not only the keys of the kingdom, but considerable for their maritime strength: thus we are told, that they were

obliged to provide eighty ships at their own charge for forty days, as often as the king should have occasion in his wars.

CINQUE-PORT is also a particular kind of fishing-net, much used in standing water; so called on account of the five entrances into it.

CION, or CYON, among gardeners, denotes a young sprig, or sprout of a tree.

CION, in anatomy, a name sometimes used for the vulva. See the article UVULA.

CIPHER, or CYPHER, one of the Arabic characters, or figures, used in computation, formed thus 0.

A cypher of itself signifies nothing; but when placed to the right of other characters, in whole numbers, it augments their value ten times; and when placed to the left in decimal arithmetic, it lessens the value in each figure in the same proportion.

CIPHER is also a kind of enigmatic character, composed of several letters interwoven, which are generally the initial letters of the persons' names for whom the ciphers are intended.

These are frequently used on seals, coaches, and other moveables. Merchants likewise, instead of arms, bear a cipher, or the initial letters of their names interwoven about a cross, of which we have many instances on old tombs.

CIPHER denotes likewise certain characters disguised and varied, used in writing letters that contain some secret, not to be understood but by those between whom the cipher is agreed on.

CIRCÆA, in botany, a plant which grows naturally in shady places in many parts of England. This plant hath a creeping root, by which it multiplies greatly. The stalks are upright, and furnished with heart-shaped leaves, placed opposite: these are of a dark green on their upper side; but pale underneath. The stalks are terminated with loose spikes of flowers, which are branched out into three or four small spikes. The flowers are small and white, having but two heart-shaped spreading petals; opposite to which are two erect hairy stamina: when the flower is decayed, the calyx becomes a rough oval capsule with two cells, each containing a single oblong seed.

CIRCENIAN GAMES, *Circenses Ludi*, a general term, under which was comprehended all combats exhibited in the Roman circus, in imitation of the Olympic games in Greece.

CIRCLE, in geometry, is a plain figure, comprehended under one line, which is called a circumference, unto which all lines drawn from a point in the middle of the figure called the center, and falling upon the circumference thereof, are all equal the one to the other. Though more properly, it is that space included within the circumference or periphery, that is the circle: however, in the popular

use of the word, circle is frequently used for the periphery alone.

Every circle is supposed to be divided into 360 equal parts, called degrees; and of all figures is the most capacious; that is, contains the greatest space or area under the least bounds or periphery.

The method of finding the circumference from the diameter or radius being given, is a problem of the greatest use in geometry. The ancients endeavoured to solve this proposition by a continual bisection of the sides of an inscribed polygon, till they arrived at a side which subtended a very small arc; they likewise found the side of a similar circumscribed polygon; then multiplying each of these by the number of sides of the polygon, they obtained the periphery of each polygon. The ratio of the diameters to the periphery of the circle will be greater than that of the same diameter to the perimeter of the circumscribed polygon; but less than that of the inscribed polygon. The difference of the two being known, the ratio of the diameter to the periphery is easily known in numbers very nearly true, though not exactly so.

But the easiest way of obtaining the circle's periphery, is by the help of fluxions and infinite series; because the fluxion of the arch is to the fluxion of its tangent in the duplicate ratio of the radius to the secant; as may be seen demonstrated in most books of fluxions.

The impossibility of expressing the exact proportion of the diameter of a circle to the circumference, by any received way of notation, and the absolute necessity of having it as near the truth as possible, has put some of the most celebrated men in all ages upon endeavouring to approximate it.

The celebrated Van Culen was the first who attempted it with any success; for by the ancient method, though so very laborious, he carried it to thirty-six decimal places, which he ordered to be engraved upon his tomb-stone. After him Mr. Abraham Sharp carried it to seventy-five places; but Mr. John Machin has carried it to one hundred, which are as follow:

If the diameter of the circle be 1, the circumference will be 3,1415926535897932384626433832795028841971693993751058209749445923078164052861089986280348253421170679, + which is a degree of exactness far more than could ever have been expected. But the ratios generally in use are as 7 to 22, as 106 to 333, as 113 to 355, as 1702 to 5347, as 1815 to 5702, or as 1 to 3,14159.

Since then if the diameter of a circle is 1, the circumference will be 3,1415926536— of the same parts; and since all circles are similar figures, by having the diameter of any circle given, we can find any other part of a circle by the following proportions.

Fig. 2. Circumferentor

Fig. 3. Circumferentor

Fig. 5. Complement

Fig. 6. 7 Composition of Motion

Fig. 8. Concave Glass

1. As 1 : 31415926536 :: any given diameter to its circumference.

2. As 1 : 7854 + :: the square of the diameter given to the area required.

3. As 1 : 8862 + :: diameter given to the side of the square; that is, equal in area to that circle.

4. As 1 : 37071 :: diameter given : side of the inscribed square.

But if the circumference of any circle be given, any of the other parts may be found by the following proportions.

1. As 1 : 318309 :: circumference given, to the diameter of that circle.

2. As 1 : 50958 :: square of the circumference given : area of that circle.

3. As 1 : 2821 :: circumference given to the side of a square = in area to that circle.

4. As 1 : 2251 :: circumference given to the side of a square inscribed in that circle.

Again, having the area of a circle, to find any of the other parts.

1. As 1 : 1,2732 :: area given : square of the diameter of that circle.

2. As 1 : 12,56637 :: area given : square of the circumference of that circle.

3. As 1 : 6366 :: area given : square of the side of the inscribed square.

We might give many more proportions of the like kind; but the above will be sufficient with proper application; however, it may not be amiss to remark, that the area of any circle is equal to half the diameter, multiplied by half the periphery.

To describe a Circle through three given Points, not in a Right-line. Let ABC be the three given points (Plate XXXIV. fig. 1.) draw two right-lines from A to B, and from B to C; then divide these two right-lines into two equal parts, by the perpendiculars GH.

CIRCULAR, in a general sense, any thing that is described or moved in a round, as the circumference of a circle, or surface of a globe.

The circular form is of all others the best disposed for motion, and the most capacious.

CIRCULAR LETTER, a letter directed to several persons who have the same interest in some common affair.

CIRCULAR LINES, in mathematics, such straight lines as are divided from the divisions made in the arch of the limb, such as sines, tangents, secants, chords, &c. See the articles SINE and TANGENT.

CIRCULAR NUMBERS, called also spherical ones, according to some, are such whole powers terminate in the roots themselves.

Thus, for instance, 5 and 6, all whose powers end in 5 and 6, as the square of 5 is 25, the square of 6 is 36, &c.

CIRCULAR SAILING is the method of sailing by the arch of a great circle. See the article SAILING.

CIRCULAR VELOCITY, in the new astronomy,

signifies the velocity of any planet, or revolving body, which is measured by the arch of a circle.

CIRCULATION, the act of moving round, or in a circle; thus we say, the circulation of the blood, the circulation of the sap, &c.

CIRCULATION of the Blood, the natural motion of the blood in a living animal, whereby that fluid is alternately carried from the heart into all parts of the body, by the arteries, from whence it is brought back to the heart again by the veins.

This motion is chiefly caused by the dilatation and contraction of this organ, and is the principle on which life depends; for when it ceases in any part, that part dies; when it is diminished, the operations are weak; and when it ceases totally, life is extinguished.

All the veins discharge themselves into the ventricles of the heart; from hence all the arteries arise: the blood expelled out of the right ventricle must be carried, through the pulmonary artery, into the lungs; from which it must be returned, by the pulmonary veins, to the left ventricle; from the left ventricle the blood thus imported is, by the constriction of that part, again expelled into the aorta, and by it distributed all over the rest of the body, and thence is returned again to the right ventricle by the cava, which completes the circulation.

This circulation becomes actually visible, with the assistance of a microscope, especially in fish, frogs, &c. wherein the inosculation, or union of the extremities of the arteries with those of the veins, together with the globules of blood flowing from the one into the other, may be plainly seen.

The circulation of the blood is generally said to have been first discovered in England, in the year 1628, by Dr. Harvey, an ingenious and learned physician; though there are others who contend for the glory of this most important discovery. Leoniscenus says, that Fran. Paoli Sarpi, a Venetian, discovered the circulation, but durst not publish his discovery for fear of the inquisition; that he therefore only communicated the secret to Fab. ab. Aquapendente, who, after his death, deposited the book he had composed on it, in the library of St. Mark, where it lay a long time, till Aquapendente discovered the secret to Harvey, who then studied under him at Padua, and who upon his return to England, a land of liberty, published it as his own. But Sir George Ent has shewn, that father Paul received the first notion of the circulation of the blood from Harvey's book on that subject, which was carried to Venice by the ambassador of the republic at the court of England.

The circulation of the blood was altogether unknown to the ancients: they thought that all the blood came from the liver, and that the greatest part of it passed into the vena cava, and so into all the branches belonging to it; but in such a manner, that, in coming

coming out from the liver, a considerable quantity of it turns about, and enters into the right cavity of the heart, where it is divided into two parts, one of which runs through the vena arteriosa, into the lungs, and the other through the medium septum into the left cavity; where they say it is converted into arterial blood, or vital spirits, which is carried into the lungs by the arteria venosa, and all over the body by the arteria magna and its branches.

CIRCULATION of the *Sap of Vegetables* is a natural motion of the nutritious juice of plants from the root to the extreme parts, and thence back again to the root.

CIRCULATION, in chemistry, is an operation whereby the same vapour, raised by fire, falls back, to be returned and distilled several times, and thus reduced into its most subtil parts.

CIRCULUS, in chemistry, an iron instrument in form of a ring, which being heated red-hot, and applied to the neck of retorts and other glass-vessels, till they grow hot, a few drops of cold water thrown upon them, or a cold blast, will make the necks fly regularly and evenly off.

Another method of doing this, is to tie a thread, first dipt in oil of turpentine, round the place where you would have it break; and then setting fire to the thread, and afterwards sprinkling the place with cold water, the glass will crack exactly where the thread was tied.

CIRCUMAGENTES MUSCULI, or **OBLIQUI MUSCULI**, in anatomy, the certain oblique muscles of the eyes, so called from helping to wind and turn the eyes about.

CIRCUMAMBIENT, an appellation given to a thing that surrounds another on all sides; chiefly used in speaking of the air. See the article **AIR**.

CIRCUMCISION, the act of cutting off the prepuce; or a ceremony in the Jewish and Mahometan religions, wherein they cut off the fore-skin of their males, who are to profess the one or the other law.

CIRCUMCISION is also the name of a feast, celebrated on the first of January, in commemoration of the circumcision of our Saviour.

CIRCUMFERENCE, in a general sense, denotes the line or lines bounding a plane figure. However, it is generally used in a more limited sense, for the curve line which bounds a circle, and otherwise called a periphery; the boundary of a right-lined figure being expressed by the term perimeter.

Any part of the circumference is called an arch, and a right-line drawn from one extreme of the arch to the other, is called a chord.

The circumference of every circle is supposed to be divided into 360 degrees. The angle at the circumference of a circle is double that at the center. See **ANGLE**.

For the ratio of the circumference of a circle to its radius, see the article **CIRCLE**.

CIRCUMFERENTOR, an instrument used by surveyors for taking angles.

It consists of a brass index and circle, all of a piece. The index is commonly about fourteen inches long, and an inch and a half broad; the diameter of the circle is about seven inches. On this circle is made a chart, whose meridian line answers to the middle of the breadth of the index, and is divided into three hundred and sixty degrees (see Plate XXXIV. fig. 2.) There is a brass ring soldered on the circumference of the circle, on which serews another ring, with a flat glass in it; so as to form a kind of box for the needle, suspended on the pivot in the center of the circle. There are also two sights to screw on, and slide up and down the index; as also a spangle and socket screwed on the back-side of the circle for putting the head of the staff in.

How to observe the Quantity of an Angle by the CIRCUMFERENTOR.

Let it be required to find the quantity of the angle *EKG* (Plate XXXIV. fig. 3.) first, place your instrument at *K*, with the flower-de-luce of the chart towards you; then direct your sights to *E*, and observe what degrees are cut by the south end of the needle, which let be 296; then, turning the instrument about, direct your sights to *G*, noting then also what degrees are cut by the south end of the needle, which suppose 247. This done, always subtract the lesser from the greater, as in this example, 247 from 296, the remainder is 49 degrees, which is the true quantity of the angle *EKG*.

CIRCUMFLEX, in grammar, one of the accents. See the article **ACCENT**.

CIRCUMGYRATION, denotes the whirling motion of any body round a center: such is that of the planets round the sun.

CIRCUMINCESSION, in theology, a term whereby the schoolmen used to express the existence of three divine persons in one another, in the mystery of the Trinity.

CIRCUMLOCUTION, a paraphractical method of expressing one's thoughts, or saying that in many words which might have been said in few.

CIRCUMLOCUTION, in oratory, is the avoiding of something disagreeable, or inconvenient to be expressed in direct terms, by imitating the sense thereof in a kind of paraphrase, so conceived as to soften and break the force thereof.

CIRCUM-POLAR STARS, an appellation given to those stars, which by reason of their vicinity to the pole, move round it without setting.

CIRCUMSCRIBED, in geometry, is said of a figure which is drawn round another figure, so that all its sides or planes touch the inscribed figure.

CIRCUMSCRIBED HYPERBOLA, one of Sir Isaac Newton's hyperbolas of the second order, that cuts its asymptotes, and contains the parts cut off within its own space.

CIRCUM-

CIRCUMSCRIBING, in geometry, denotes the describing a polygonous figure about a circle, in such a manner, that all its sides shall be tangents to the circumference.

Sometimes the term is used for the describing a circle about a polygon, so that each side is a chord; but in this case it is more usual to say the polygon is inscribed, than the circle is circumscribed.

CIRCUMSCRIPTION, in natural philosophy, the termination, bounds, or limits of any natural body.

CIRCUMSPECTE AGATIS, in law, a statute prescribing certain cases to the judges, wherein the king's prohibition does not lie.

CIRCUMSTANCE, particularity which, tho' not essential to any action, yet doth some way affect it.

CIRCUMSTANTIBUS, in law, a term used for supplying and making up the number of jurors, in case any impannelled appear not, or appearing, are challenged by either party, by adding to them so many of the persons present, as will make up the number, in case they are properly qualified.

CIRCUMVALLATION, *the Line of*, a fortification of earth, consisting of a parapet and trench, which are made round the town intended to be besieged, when any molestation is apprehended from parties of the enemy, which may march in order to relieve the place.

Before the attack of a place is begun, care is to be taken to have the most exact plan of it possible, and upon this, the line of circumvallation, and the attack, are projected. The line of circumvallation, being a fortification opposed to an enemy that may come from the open country to relieve the besieged, ought to have its defences directed against him; that is, so as to fire from the town; and besiegers ought to be encamped behind this line, and between it and the place. The camp ought to be as much as possible out of the reach of the shot of the place; and the line of circumvallation, which is to be farther distant from the place than the camp, ought much more to be out of the reach of its cannon.

As cannon are never to be fired from the rear of the camp, this line should be upwards of 1200 fathoms from the place; we will suppose its distance fixed at 1400 fathoms from the covered-way. The thickness or depth of the camp may be computed about 30 fathoms, and from the head of the camp to the line of circumvallation there ought to be a space of 120 fathoms, that the army may be drawn up in order of battle at the head of the camp behind the circumvallation; this distance added to the 30 fathoms allowed for the depth of the camp makes 150 fathoms, which being again added to the distance of the covered-way from the rear of the camp, makes 1550 fathoms for the distance of the circumvallation from the covered-way.

Sometimes also an advanced fosse or ditch is made before the line, about 12 or 15 feet wide, 6 or 7 feet deep, and about 12 or 15 fathoms distant from the fosse of the line. The design of this ditch is to stop the enemy when he advances to attack the line, and make him lose time and men in passing it. For as it is absolutely under the fire of the line, the enemy must necessarily lose many soldiers during the time of his passage over it; and the passing this ditch may also so break and disconcert the order of the enemy, as to prevent his attacking with the same advantage, as he might have done if he had not been obstructed by it.

It will be sufficient to observe, with *M. Vauban*,

First, That the circumvallation ought to occupy the most advantageous part of the ground before the place; that is to say, the most easy to defend, the most difficult to attack, and the most adapted to the security and conveniency of the troops; and that the redans ought to be placed on the most eminent places, and not in bottoms.

Secondly, That the cannon of the place do not play upon the rear of the camp.

Thirdly, Never to carry the lines too far into the field, nor to occupy more ground than is necessary for the security of the camp.

Fourthly, To possess all places from which the line may be commanded, when it may be done without carrying the circumvallation too far; and also to construct this line so as that it may take advantage of all the declivities, eminences, rivers, morasses, and in general of all which may render the access to it more difficult. If there are woods and thickets within its circumference, it may be covered on those quarters by felling the trees.

Fifthly, If there be any rivers or brooks within the circumvallation, which divide the ground into several parts, care must be taken to provide a great number of bridges for the communication of all the quarters, that, in case of an attack, they may with ease and speed mutually assist each other.

It is not difficult to trace out these lines upon a good topographical chart or plan of the place and country adjacent, since nothing more is necessary than to carry on all the parts of the line at about 1800 fathoms from the center of the place, and to dispose them in such a manner as that there may be a distance of about 120 fathoms from the point of one redan to the point of another.

Nor is there any more difficulty in tracing out these lines on the ground, to those who know any thing of practical geometry, it being too easy to need an explanation here. See the article **CONTRAVALATION**.

CIRCUMVOLUTION, in architecture, signifies the torus of the spiral line of the Ionic volute.

CIRCUS, in antiquity, a great building of a round or oval figure, erected by the ancients, to exhibit shews to the people.

CIRRI, among botanists, fine strings of thread like filaments, by which some plants fasten themselves to the walls, trees, &c. such are those of ivy.

CIRRI, in ichthyology, certain oblong and soft appendages, not unlike little worms, hanging from the under jaws or mouths of some fishes: these cirri, commonly translated beards, afford marks to distinguish the different species of the fish, on which they are found.

CIRSOCELE, or **HERNIA VARICOSA**, in surgery, a preternatural distention or divarication of the spermatic veins in the process of the peritonæum, immediately above the testicle, and sometimes higher up in the scrotum, or even in the groin, inasmuch that they resemble the intestines of a bird, and equal the size of a goose-quill, with varicose nodes, by which means the testicle appears much bigger, and hangs down lower than it should do.

CISLEU, in Hebrew chronology, the ninth month of their ecclesiastical, and the third of the civil year, answering nearly to our November.

CISSAMPELOS, in botany, a genus of twining plants, which grow in the warmest parts of America: they produce male and female flowers on distinct plants; those of the male grow in short spikes or clusters, and are of a pale herbaceous colour. They are apetalous, having a monophyllous calyx, divided into four parts with a single style. The female flowers are produced in long loose racemi from the side of the stalks. These have a calix like the male; and instead of petals, have four nectariums standing round an hairy oval germen, which afterwards becomes a pulpy globose berry, containing a single seed.

This genus being tender, requires a hot-house in this climate, and are the same as the caapeba of Plumier.

CISSOID, in the higher geometry, an algebraic curve, first invented by Diocles, an ancient Greek-geometrician, whence it is peculiarly called the Cissoid of Diocles: its chief use is for finding two mean proportionals between two given right lines; but Sir Isaac Newton, in his *Enumeratio linearum tertii Ordinis*, reckons it amongst one of the defective hyperbolas, being according to him the forty-second species.

CISSUS, in botany, a genus of plants whose flower consists of a polyphyllous small involucrem, with a plane monophyllous cup, which contains four concave petals. The fruit is a rotundated umbilicated berry, containing an osculated roundish seed.

CISTERCIANS, in church history, a religious order founded in the eleventh century by St. Robert, a Benedictine. They became so powerful, that they governed almost all Europe, both in spirituals and temporals. Cardinal de Vitri, describing their observances, says, they never wear skins not shirts, nor ever eat flesh, except in sickness; and abstained

from fish, eggs, milk, and cheese: they lay upon straw-beds in their tunics and cowls: they rose at midnight to prayers: they spent the day in labour, reading, and prayer: and in their exercises observed a continual silence. The habit of the Cistercian monks is a white robe, in the nature of a cassock, with a black scapulary and hood, and is girt with woollen girdle. The nuns wear a white tunic, and a black scapulary and girdle.

CISTERN denotes a subterraneous reservoir of rain water; or a vessel serving as a receptacle for rain or other water for the necessary uses of a family.

CISTUS, in botany, a genus of plants, the flower of which consists of five large roundish patent petals which spread open, and contains a number of short, hairy filaments, topped with small, roundish antheræ; the fruit is a roundish capsule, containing a number of small seeds.

There are various kinds of this genus, which are very great ornaments to a garden; their flowers are produced in great plenty all over the shrubs, which though of short duration, yet are succeeded by fresh ones almost every day for above two months successively: these flowers are many of them about the bigness of a middling rose, but single, and are of different colours.

From a species of cistus, called by C. Bauhine, cistus ladanifera, the balsam or gum ladanum, is extracted, which is common in Cyprus, and some parts of Arabia; and Tournefort describes the method of gathering this gum in Candia. He says, it is brushed off the leaves of the shrub in a calm day, by a sort of whip, composed of many straps, to which it adheres, and afterwards it is scraped off the straps, and made into cakes of different sizes.

CITADEL, a place fortified with four, five, or six bastions, built on a convenient ground near a city, that it may it command in case of a rebellion. The city therefore is not fortified on the part opposite to the citadel, though the citadel is against the city. The best form for a citadel is a pentagon, a square being too weak, and a hexagon too big.

CITATION, in ecclesiastical courts, is the same with summons in civil courts.

CITHARA, in antiquity, a musical instrument, the precise structure of which is not known; some think it resembled the Greek delta Δ ; and others, the shape of a half moon. At first it had only three strings, but the number was at different times increased to eight, to nine, and lastly to twenty-four. It was used in entertainments and private houses, and played upon with a plectrum or quill, like the lyre. See the article **LYRE**.

CITHAREXYLON, in botany, a tree which grows in most of the West-Indian islands, where it rises to a great height, the wood of which is much esteemed for building, being very durable. It rises with an upright trunk to the height of fifty or sixty feet, sending out branches on every side; these

have

have several angles or ribs running longitudinally, and are furnished with oval, lanceolated leaves, serrated on their edges, of a pale or whitish colour on their upper side, and very prominent beneath. The flowers come out from the sides and ends of the branches in loose spikes, each of which are monopetalous and funnel-shaped, divided at the top into five parts, which spread open. The fruit is a roundish, unilocular berry, containing two ovated seeds.

This plant is propagated by seeds or cuttings, and requires a hot-house for their preservation in this climate.

CITIZEN, *Civis*, a native or inhabitant of a city, vested with the freedom and liberties of it.

CITRINUS, in natural history, a kind of spring crystal, of a fine yellow colour, which being set in rings, is often mistaken for a topaz.

CITRON-TREE, *Citrus*, in botany. See the article **CITRUS**.

CITRUL, *Citrullus*, makes a distinct genus of plants, according to some, otherwise called *anguria*; but Linnæus comprehends it among the cucumbers: it is said to have the same medicinal qualities with the cucurbita or gourd.

CITRUS, or *Citrum*, the citron-tree, in botany, an ever-green plant with a slender trunk, the wood of which is white and hard, and the bark of a pale green colour. The leaves are somewhat like those of the orange, generally blunt, but now and then acuminate. The flowers, which grow in the tops of the branches, are like those of the orange, the petals being more fleshy. The fruit is in shape and size like the orange, but coloured like the lemon, and the juice higher flavoured and more of the perfume in it than either.

Citrons in Italy are not used as an aliment, but as a sauce, and are cut into small slices, as we do lemons, to garnish the dishes, and to squeeze upon the meat; the acid is very agreeable, excites a weak appetite, and helps digestion, when used moderately. It is an excellent remedy against the scurvy, and is a kind of specific to cure that disease; when the gums of persons are ulcerated with this disorder, the juice will perfect a cure.

Citron-juice is also good in burning and malignant fevers, to quench thirst, and to restrain the heat and effervescence of the blood. When the juice is mixed with water, and sweetened with sugar, it makes a fine cooling drink, grateful to the palate, and agrees with both sick and well. The juice of citrons is likewise diuretic, cleanses the kidneys of small gravel, and restrains vomiting proceeding from bilious humours. From the bark and flowers of this plant we have oils, essences, confections, and waters obtained, of which considerable quantities are imported.

The citron-tree is propagated and managed with us in the same manner as the orange-tree, (to

which we refer the reader) but being rather more tender than the orange, they should have a green-house with a flue in it, to preserve them in winter in this country.

With the citron, Linnæus has classed the orange and lemon, under the general name *citrus*; but they being distinctly noticed, not only here but in the southern parts of Europe, where they are most plenty, it was thought necessary in this work to mention them separately.

CITY, *Civitas*, or *Urbs*, a large populous town, capital of some country, province, or district, and the see of a bishop.

Town and city are frequently used in a synonymous sense; however, custom seems to have appropriated the term city to such towns as are, or formerly were, the sees of a bishop: hence it is, that Edinburgh, Glasgow, &c. are still called cities, though they are no longer the sees of bishops, since the establishment of presbytery in Scotland.

CIVET, a soft unctuous odoriferous substance, about the consistence of honey or butter; of a whitish, yellowish, or brownish colour, and sometimes blackish, brought from the Brazils, the coast of Guinea, and the East-Indies; found in certain bags situated in the lower part of the belly of an animal of the cat kind. The bag has an aperture externally, by which the civet is shed or extracted. See **ZIBETHICUM**.

This substance has a very fragrant smell, so strong as, when undiluted, to be disagreeable; and an unctuous subacid taste. It is used chiefly in perfumes, rarely or never for medicinal purposes, though the singular effects which musk has been lately found to produce may serve as an inducement to the trial. It unites with oils, both expressed and distilled, and with animal fats: in watery or spirituous liquors it does not dissolve, but both menstrua may be strongly impregnated with its odoriferous matter, water by distillation, and rectified spirit by digestion; by trituration with mucilages, it becomes soluble in water.

CIVET-CAT. See **ZIBETHICUM**.

CIVIC CROWN, *Corona Civica*, was a crown given by the ancient Romans to any soldier who had saved the life of a citizen in any engagement.

This was accounted more honourable than any other crown, though composed of no better materials than oaken boughs.

CIVIL, *Civilis*, in a general sense, something that regards the policy, public good, or peace of the citizens, or subjects of the state; in which sense we say, civil government, civil law, civil right, civil war, &c.

CIVIL, in a legal sense, is also applied to the ordinary procedure in an action, relating to some pecuniary matter or interest, in which sense it is opposed to criminal.

CIVIL-LAW is properly the peculiar law of each state, country, or city: but what we usually mean by the civil-law, is a body of laws composed out of the best Roman and Grecian laws, compiled from the laws of nature and nations, and, for the most part, received and observed throughout all the Roman dominions for above 1200 years.

The civil-law is used in England in the ecclesiastical courts, in the courts of the admiralty, and in the two universities; yet in all these it is restrained and directed by the common law.

CIVIL WAR, a war between people of the same state, or the citizens of the same city.

CIVIL YEAR is the legal year, or the annual account of time, which every government appoints to be used within its own dominions; and is so called in contradistinction to the natural year, which is measured exactly by the revolution of the heavenly bodies.

CIVILIAN, in general, denotes something belonging to the civil law; but more especially the doctors and professors thereof are called civilians: of these we have a college or society in London, known by the name of Doctors-commons.

CLACK, among countrymen. To clack wool, is to cut off the sheep's mark, which makes the weight less, and yields less custom to the king.

CLAIM, in law, a challenge of interest in any thing that is in possession of another, as claim by charter, descent, acquisition, &c.

CLAIM of Liberty, is a suit to the king in the court of Exchequer, to have liberties confirmed there by the attorney-general.

False CLAIM is a term used in the forest-laws, where a person claims more than his due, for which he is liable to be amerced.

CLAIR - OBSCURE, **CHIAIRO - SCURO**, or **CLARO-OBSCURO**. See the article **CLARO-OBSCURO**.

CLAMP, among brickmakers, implies a pile of unburnt bricks built up for burning. These clamps are built much after the same manner as arches are built in kilns, viz. with a vacuity betwixt each brick's breadth for the fire to ascend by, but with this difference, that instead of arching, they truss over, or over-span, that is, the end of one brick is laid about half way over the end of another, and so till both sides meet within half a brick's length, and then a binding brick at the top finishes the arch.

CLAMPS, in naval architecture, thick planks in a ship's side, which support the ends of the beams. See **BEAMS**.

CLAMPS are also small crooked plates of iron, forelocked upon the trunnions of the cannon, to keep them steady in their carriages at sea.

CLAMPS are likewise frequently used to fasten the masts or bowsprits of small vessels and boats.

CLAMP NAILS, such nails as are used to fasten on clamps in the building or repairing of ships.

CLAMPING, in joinery, is the fitting of a piece of board with the grain, to another piece of board cross the grain. Thus the ends of tables are commonly clamped to prevent their warping.

CLAP, in medicine, the first stage of the venereal disease, more usually called a gonorrhoea. See **GONORRHOEA**.

CLAP-BOARD, among coopers, denotes any kind of board proper for making casks and other vessels of.

CLAR, or **CLAER**, among metallurgists, denotes the powder of bone-ashes, kept for covering the insides of coppers.

CLARENCIEUX, the second king at arms, so called from the duke of Clarence, to whom he first belonged; for Lionel, third son to Edward III. having by his wife the honour of Clare, in the county of Thomond, was afterwards declared duke of Clarence; which dukedom afterwards escheating to Edward IV. he made this earl a king at arms. His office is to marshal and dispose of the funerals of all the lower nobility, as baronets, knights, esquires, on the south-side of the Trent; whence he is sometimes called Surroy, or South-roy, in contradistinction to Norroy.

CLARENDON. The constitutions of Clarendon are certain ecclesiastical laws drawn up at Clarendon near Salisbury. They were sixteen in number, all tending to restrain the power of the clergy, and readily assented to by all the bishops and barons, the archbishop Becket excepted, who opposed them at first, but was afterwards prevailed upon to sign them. Pope Alexander III. declared against and annulled most of these.

CLARET, a name given by the French to such of their red wines as are not of a deep or high colour. See **WINE**.

CLARET-WINE-APPLE, is fair, and yields plenty of a pleasant sharp juice, from whence it has its name, and not from the colour, it being a white apple, but makes a vigorous liquor, which, if well ordered, excels most other cyders, especially with a mixture of sweet apples.

CLARICHORD, or **MANICHORD**, a musical instrument in form of a spinnet.

It has forty-nine or fifty stops, and seventy strings, which bear on five bridges, the first whereof is the highest, the rest diminishing in proportion. Some of the strings are in unison, their number being greater than that of the stops. There are several little mortises for passing the jacks, armed with brass-hooks, which stop and raise the chords instead of the feather used in virginals and spinnets: but what distinguishes it most is, that the chords are covered with pieces of cloth, which render the sound sweeter, and deaden it so, that it cannot be heard at any considerable

considerable distance; whence it comes to be particularly in use among the nuns, who learn to play, and are unwilling to disturb the silence of the dormitory.

CLARIFICATION, in chemistry. See the article **DEBURATION**.

CLARINO, a trumpet: hence, *a doi clarini*, signifies that a piece of music is to be played by two trumpets. See the articles **TRUMPET**, **CORNET**, &c.

CLARION, a kind of trumpet, whose tube is narrower, and its tone acuter and shriller than that of the common trumpet.

CLARION, in heraldry. He bears ruby, three clarions topaz, being the arms of the earl of Bath, by the name of Granville. Guillim is of opinion, that these three clarions are a kind of old-fashioned trumpets; but others say, that they rather resemble the rudder of a ship; others a rest for a lance.

CLARK-GOOSE, in ornithology, a kind of wild goose, found in Zetland.

CLARO-OBSCURO, or **CLAIR-OBSCURO**, in painting, the art of distributing to advantage the lights and shadows of a piece, both with regard to the easing of the eye, and the effect of the whole piece.

Thus, when a painter gives his figure a strong relief, loosens them from the ground, and sets them free from each other, by the management of lights and shadows, he is said to understand the *claro-obscuro*, which makes one of the great divisions or branches of painting, the whole of a picture being resolvable into light and shadow.

CLARO-OBSCURO, or **CHIAIRO-SCURO**, is also used to signify a design consisting only of two colours, most usually black and white, but sometimes black and yellow; or it is a design washed only with one colour, the shadows being of a dusky brown colour, and the lights heightened up with white.

The word is also applied to two prints of two colours, taken off at twice, whereof there are volumes in the cabinets of the curious in prints.

CLARY, in botany, the English name of the *felærea* of Tournefort, comprehended by Linnæus among the species of *salvia*, or sage.

Wild CLARY, the same with the *horminum* of Tournefort; likewise accounted by Linnæus a species of sage.

CLASPERS, among gardeners, the same with what botanists call *cirri*. See **CIRRI**.

CLASS, *classis*, an appellation given to the most general subdivisions of any thing: thus animal is subdivided into the classes quadrupeds, birds, fishes, vegetables, &c. which are again subdivided into series or orders; and these last into genera.

CLASS is also used in schools, in a synonymous sense with form, for a number of boys all learning the same thing.

CLASSIC, or **CLASSICAL**, an epithet chiefly

applied to authors read in the classes at schools, and who are in great authority there.

By classical learning may be understood, such an intimacy with the best Greek and Latin writers, as not only enables the reader to see and admire the beauty of their several compositions, but to imitate their manner of writing, to transcribe their spirit and eloquence, and make their diction and their sentiment his own.

CLAVELLATI CINERES, the same with pot-ashes. See the article **POT-ASHES**.

CLAVICLES, *claviculæ*, in anatomy, are two bones situated transversely and a little obliquely opposite to each other, at the superior and anterior part of the thorax, between the scapula and sternum.

The uses of the clavicles are, 1. To keep the arms from falling too forward upon the breast, and to facilitate several of the motions of the arm. 2. To serve for the place of origin for several muscles. 3. To defend the great subclavian vessels which run under them.

CLAVIS properly signifies a key, and is sometimes used in English to denote an explanation of some obscure passages in any book or writing.

CLAVUS, in antiquity, an ornament upon the robes of the Roman senators and knights, which was more or less broad, according to the dignity of the person: hence the distinction of *tunica angusticlavia* and *laticlavia*.

CLAVUS, in medicine and surgery, is used in several significations: 1. *Clavus hytericus* is a shooting pain in the head, between the pericranium and cranium, which affects such as have the green-sickness. 2. *Clavus oculorum*, according to Celsus, is a callous tubercle on the white of the eye, taking its denomination from its figure. 3. *Clavus* imports indurated tubercles of the uterus. 4. *Clavus* imports a surgical instrument of gold, mentioned by Amatus Lusitanus, designed to be introduced into an excoriated palate, for the better articulation of the voice. 5. *Clavus* is a callus or corn on the foot: this arises from a too great compression of the cutis, which by this means hardens and forms itself into a knot. The cure is by softening them, and then pulling them out. The pulp of a lemon laid to a corn, and bound on all night, often softens it so by the morning, that it may easily be taken off.

CLAW, among zoologists, denotes the sharp-pointed nails with which the feet of certain quadrupeds and birds are furnished.

CLAY, *argilla*, in natural history, a genus of earths, the characters of which are these: they are firmly coherent, weighty, and compact; stiff, viscid, and ductile to a great degree, while moist; smooth to the touch, not easily breaking between the fingers, nor readily diffusible in water, and when mixed, not readily subsiding from it.

Besides the use of clay for making potter's ware, it is a considerable improver of light and sandy grounds,

grounds, which, unless they be clayed, will bear nothing but rye, with whatever other composites they be manured; but once clayed, they will produce oats, barley, pease, &c.

CLAY-LANDS, those abounding with clay, whether black, blue, yellow, white, &c. of which the black and the yellow are the best for corn.

All clay-soils are apt to chill the plants growing on them in moist seasons, as they retain too much water: in dry seasons, on the contrary, they turn hard and choke the plants. Their natural produce is weeds, goose-grass, large daisies, thistles, docks, poppies, &c. Some clay-soils will bear clover and rye-grass; and, if well manured, will produce the best grain: they hold manure the best of all lands, and the most proper for them are horse-dung, pigeon's dung, some kinds of marle, folding of sheep, malt-dust, ashes, chalk, lime, soot, &c.

CLAYTONIA, in botany, a plant which grows naturally in Virginia. It hath a small, tuberous, dark-coloured root, from whence arises in the spring, several slender stalks about three inches high, each having two or three succulent narrow leaves, of a deep green colour. From the top of the stalk comes forth four or five flowers in a loose bunch; each of these are composed of five white petals, which are emarginated and spotted with red on their inner side, and contains the same number of recurved filaments, which are terminated with oblong incumbent anthers. The fruit is a roundish, trilobular capsule, opening with three elastic valves, containing several roundish seeds.

CLEATS, in the marine, pieces of wood having one or two projecting ends whereby to fasten the ropes: some of them are fastened to the shrouds below for this purpose, and others nailed to different places of the ship's deck or sides.

CLEAVERS, *aparine*, in botany, &c. See the article *APARINE*.

CLECHE, in heraldry, a kind of cross, charged with another cross of the same figure, but of the colour of the field.

CLEDGE, among miners, denotes the upper stratum of fuller's earth.

CLEF, or CLIFF, in music, a mark set at the beginning of the lines of a song, which shews the tone or key in which the piece is to begin; or it is a letter marked on any line which explains the rest. It is called clef, or key, because hereby we know the names of all the other lines, and consequently the quantity of every degree or interval: but because every note in the octave is also called a key, this letter marked is, for distinction sake, denominated the signed clef; and by this key is meant the principal note of a song, in which the melody closes.

There are three signed clefs, *c*, *f*, *g*; the clef of the highest part in a song, called treble, or alt, is *g* on the second, sometimes on the first, and sometimes on the third line, counting upwards. The

clef of the bass, or lowest part, is *f*, generally on the fourth line upwards, and often on the second, third, and fifth: for all the other mean parts, the clef in *c*, sometimes on one, and sometimes on another line; indeed some that are really mean parts are frequently set with the clef *g*. See *TREBLE*, *TENOR*, and *BASS*.

CLEFTS, or CRACKS in the Heels, a disease incident to horses, which comes either by over-hard labour, which occasions furfets, or by giving them unwholesome meat, or by washing them when hot. For the cure, shave away the hair, and apply the oil of hempseed, or linseed; and be sure to keep them clean.

CLEMATIS, virgin's bower, in botany, a genus of plants, the flower of which is composed of four loose oblong petals, having a great number of subulated filaments, with antheræ adhering to their sides: it hath many gemina, which are roundish and compressed, which afterwards become so many seeds of the same form, each crowned with a feather-shaped style. There are various species belonging to this genus, which have all of them climbing branches, and may be propagated by laying. Some of the sorts are very agreeable, and proper to run over arbours, &c. particularly those which produce double flowers.

CLEPSYDRA, an instrument or machine serving to measure time by the fall of a certain quantity of water.

The word comes from *κλεψω*, *condo*, and *υδωρ*, *aqua*, water.

There have likewise been clepsydræ made with mercury.

The Egyptians, by this machine, measured the course of the sun. Tycho Brahe, in our days, made use of it to measure the motion of the stars, &c. and Dudley used the same contrivance in making all his maritime observations.

The use of clepsydræ is very ancient: they were invented in Egypt under the Ptolemies; as were also sun-dials. Their use was chiefly in the winter; the sun-dials served in the summer. They had two great defects; the one, that the water ran out with a greater or less facility, as the air was more or less dense; the other, that the water ran more readily at the beginning, than towards the conclusion.

M. Amontons has invented a clepsydra free from both these inconveniences, and which has these three grand advantages; of serving the ordinary purpose of clocks; of serving in navigation for the discovery of the longitude; and of measuring the motion of the arteries.

Construction of a CLEPSYDRA. To divide any cylindric vessel into parts to be emptied in each division of time; the time wherein the whole, and that wherein any part is to be evacuated, being given.

Suppose, a cylindric vessel, whose charge of
water

water flows-out in twelve hours, were required to be divided into parts to be evacuated each hour. 1. As the part of time 1, is to the whole time 12, so is the same time 12 to a fourth proportional, 144. 2. Divide the altitude of the vessel into 144 equal parts: here the last will fall to the last hour; the three next above to the last part but one; the five next to the tenth hour, &c. Lastly, the 23 last to the first hour.

For since the times increase in the series of the natural numbers 1, 2, 3, 4, 5, &c. and the altitudes, if the numeration be in retrograde order from the twelfth hour, increase in the series of the unequal numbers 1, 3, 5, 7, 9, &c. the altitude, computed from the twelfth hour, will be as the squares of the times 1, 4, 9, 16, 25, &c. therefore the square of the whole time 144, comprehends all the parts of the altitude of the vessel to be evacuated. But a third proportional to 1 and 12 is the square of 12, and consequently it is the number of equal parts into which the altitude is to be divided, to be distributed according to the series of the unequal numbers, through the equal interval of hours. Since in lieu of parts of the same vessel, other less vessels equal thereto may be substituted; the altitude of a vessel emptied in a given space of time being given, the altitude of another vessel to be emptied in a given time may be found, viz. by making the altitudes as the squares of the times. Hence we see the method of constructing the clepsydræ used by the ancients.

CLEPSYDRA is also used for an hour-glass of sand, and likewise for a water-clock. See the articles HOUR-GLASS and WATER-CLOCK.

CLERGY, *Clorus*, *κλρος*, a general name given to the body of ecclesiastics of the Christian church, in contradistinction to the laity.

Benefit of CLERGY, is an ancient privilege, whereby one in orders claimed to be delivered to his ordinary, to purge himself of felony: this purgation was to be by his own oath, affirming his innocence, and the oath of twelve purgators, as to their belief of it, before a jury of twelve clerks: if the clerk failed in his purgation, he was deprived of his character, whereby he became a mere layman; or he was to be kept in prison till a pardon was obtained; but if he purged himself, he was set at liberty.

This was formerly admitted, even in cases of murder; but the ancient course of the law is much altered upon this head. By the statutes of 18 Eliz. cap. vii. clerks are no more committed to their ordinary to be purged; but every man, to whom the benefit of clergy is granted, though not in orders, is put to read at the bar, after he is found guilty and convicted of such felony, and so burnt on the hand, and set free for the first time, if the ordinary or deputy standing by do say, *legit ut clericus*, otherwise he shall suffer death.

CLERK, a word originally used to denote a

learned man, or man of letters; whence the term became appropriated to churchmen, who were from thence called clerks or clergymen: the nobility and gentry being usually bred up to the exercise of arms, and none left but the ecclesiastics to cultivate the sciences.

CLERK is also applied to such as by their course of life exercise their pens in any court or office, of which there are various kinds.

CLEROMANCY, *κλρομαντεια*, a sort of divination, performed by throwing lots, which were generally black and white beans, little clods of earth, or pebbles; also dice, or such like things, distinguished by certain characters. They cast the lots into a vessel, and having made supplication to the gods to direct them, drew them out, and according to the characters, conjectured what should happen to them.

CLIENT, *Clients*, among the Romans, a citizen who put himself under the protection of some great man, who, in respect of that relation, was called patron. This patron assisted his client with his protection, interest, and goods; and the client gave his vote for his patron, when he sought any office for himself or his friends. Clients owed respect to their patrons, as these owed them their protection.

The right of patronage was appointed by Romulus, to unite the rich and poor together in such a manner, as that one might live without contempt, and the other without envy; but the condition of a client, in course of time, became little else but a moderate slavery.

CLIENT is now used for a party in a law-suit, who has turned over his cause into the hands of a counsellor or solicitor.

CLINCH, or CLENCH, in naval affairs. That part of a cable, or other rope, which is fastened to the anchor, is called the clinch, and the act of fastening is called clinching.

A peculiar method of fastening a rope to a post, &c. is also called clinching.

CLIMACTERIC, *Annus Climactericus*, among physicians and natural historians, a critical year in a person's life, in which he is supposed to stand in great danger of death.

According to some, every seventh year is a climacteric; but others allow only those years produced by multiplying 7, by the odd number 3, 5, 7, and 9, to be climacterical. These years, they say, bring with them some remarkable change with respect to health, life, or fortune; the grand climacteric is the sixty third year; but some making two, add to this the eighty-first: the other remarkable climacterics are the seventh, twenty-first, thirty-fifth, forty-ninth, and fifty-sixth. The credit of climacteric years can only be supported by the doctrine of numbers introduced by Pythagoras; though many eminent men,

best

both among the ancients and moderns, appear to have great faith in it.

CLIMATE, in geography, is a tract of the surface of the earth included between two parallels to the equator, such that the longest day of the lesser parallel exceeds that of the greater by half an hour.

These climates are narrower the farther they are from the equator; therefore supposing the equator the beginning of the first climate, the polar circle will be the end of the 24th climate; for afterwards, the longest day encreases not by half hours, but by days and months. The following table of the climates shews the lengths of the longest days, and the latitude at the ends of each climate, together with the breadth thereof. So that having the climate given, the latitude is found: or having the latitude given, the climate and longest day are found.

Climate.	Length of days. H.	Latitude.	Breadth.
1	12 $\frac{1}{2}$	8.34	8.34
2	13	16.43	7.50
3	13 $\frac{1}{2}$	23.11	7. 3
4	14	30.47	6. 9
5	14 $\frac{1}{2}$	36.30	5.17
6	15	41.22	4.30
7	15 $\frac{1}{2}$	44.29	3.48
8	16	49. 1	3.13
9	16 $\frac{1}{2}$	51.58	2.44
10	17	54.29	2.17
11	17 $\frac{1}{2}$	56.37	2.00
12	18	58.26	1.40
13	18 $\frac{1}{2}$	59.59	1.26
14	19	61.18	1.13
15	19 $\frac{1}{2}$	62.25	1.01
16	20	63.22	0.52
17	20 $\frac{1}{2}$	64.06	0.44
18	21	64.46	0.36
19	21 $\frac{1}{2}$	65.21	0.29
20	22	65.47	0.22
21	22 $\frac{1}{2}$	66.06	0.17
22	23	66.20	0.11
23	23 $\frac{1}{2}$	66.28	0. 4
24	24	66.30	0. 1

The difference of climates arises from the different inclination or obliquity of the sphere. The ancients used to reckon the parallel in which the length of the longest day is twelve hours and three quarters, for the beginning of the first climate. It was likewise a custom among them, instead of the method now among us of setting the latitudes of places down in degrees and minutes, to content themselves with saying what climate the place under consideration was situated.

The term climate is vulgarly made use of to signify any country or region differing from one another, either in respect of the seasons, the quality of the soil, or even the manners of the inhabitants, without any regard to the length of the longest day.

CLIMAX, or GRADATION, in rhetoric, a figure wherein the word or expression which ends the first member of a period begins the second, and so on: so that every member will make a distinct sentence, taking its rise from the next foregoing, till the argument and period be beautifully finished: or, in the terms of the schools, it is when the word or expression, which was predicate in the first member of a period, is subject to a second, and so on, till the argument and period be brought to a noble conclusion; as in the following gradation of Dr. Tillotson. "After we have practised good actions a while, they become easy; and when they are easy, we begin to take pleasure in them; and when they please us, we do them frequently; and by frequency of acts, a thing grows into a habit; and confirmed habit is a second kind of nature, and so far as any thing is natural, so far it is necessary, and we can hardly do otherwise; nay, we do it many times, when we do not think of it."

CLINIC, a term applied by the ancient church-historians, to those who received baptism on their death-bed.

CLINIC, in a modern sense, is seldom used but for a quack, or rather for an empirical nurse, who pretends to have learned the art of curing diseases by attending on the sick.

CLINIC MEDICINE, *Medicina Clinica*, was particularly used for the method of visiting and treating sick persons in bed, for the more exact discovery of all the symptoms of their disease.

CLINOIDES, in anatomy, are four small processes in the inside of the os sphenoides, forming a cavity called sella turcica, in the middle of that bone, in which lies the glandula pituitaria.

CLITORIS, or as some call it, *Mentula Muliebris*, in anatomy, a part of the external female pudenda, situated at the angle which the nymphæ form with each other.

CLOACA, in Roman antiquity, the common sewer, by which the filth of the city of Rome was carried away.

CLOACA, in comparative anatomy, imports the canal in birds, through which the egg descends from the ovary in its exit.

CLOCK, a kind of movement, or machine, serving to measure and strike time.

The usual chronometers are watches and clocks: the former in strictness are such as shew the parts of time; the latter, such as publish it striking: though the name watch is originally appropriated to pocket clocks;

in (Plate XXXV. *fig. 1.*) then will the sun's light in passing through this prism suffer different degrees of refraction, and by that means be parted into different rays, which rays, being received upon a clean white paper, will exhibit the following colours, viz. red, orange, yellow, green, blue, indigo, and a violet purple. Thus let AB (Plate XXXV. *fig. 2.*) represent the window-shutter, C the hole in it, DEF the prism, ZY a ray of light coming from the sun, which passes through the hole, and falls upon the prism at Y; and if the prism were removed, would go on to X, but in entering its first surface EF shall be refracted into the course YW, falling upon the second in W, where, in going out into the air, it shall be refracted again.

Let the light now, after it has passed the prism, be received upon a sheet of white paper GHIK, held at a proper distance, and it will exhibit upon the paper a picture or image at LM, of an oblong figure, whose ends are semi-circular, and sides straight. And it shall be variegated with colours after the following manner.

From the extremity M, to some length, suppose to the line *no*, it shall be of an intense red; from *no* to *pg* it shall be of an orange colour; from *pg* to *rs* it shall be yellow; from thence to *tu* it shall be green; from thence to *vx* blue; from thence to *yz* indigo; and from thence to the end violet. And if the whole image be divided lengthwise into 360 equal parts, the red shall take up 45 of them, the orange 27, the yellow 48, the green 60, the blue 60, the indigo 40, and the violet 80.

Sir Isaac Newton, in his *Optics*, has shewn how, from the refraction of the most refrangible and least refrangible rays, to find the refraction of all the intermediate ones. His rule is this; if the sine of incidence be to the sine of refraction in the least refrangible rays, as AV to BC (*fig. 3.*) and to the sine of refraction in the most refrangible, as AV to BD; and if CE be taken equal to CD, and then ED be so divided in F, G, H, I, K, L, that ED, EF, EG, EH, EI, EK, EL, EC, may be proportional to the eight lengths of musical chords, which shall sound the notes in an octave, ED being the length of the key, EF the length of the tone above that key, EG the length of the lesser third, EH of the fourth, EI of the fifth, EK of the greater sixth, EL of the seventh, and EC of the octave above that key; that is, if the lines ED, EF, EG, EH, EI, EK, EL, and EC, appear the same proportion to each other, as the numbers 1, $\frac{9}{8}$, $\frac{5}{4}$, $\frac{4}{3}$, $\frac{3}{2}$, $\frac{5}{3}$, $\frac{15}{8}$, $\frac{2}{1}$, respectively, then shall BD and BF be the limits of the fines of refraction of the violet rays; that is, the violet coloured rays shall not all of them precisely have the same sine of refraction; but none of them shall have a greater sine than BD, nor a less than BF, though there be violet-coloured rays which answer to any sine of refraction that can be taken between these two. In

the same manner BF and BG are the limits of the fines of refraction of the indigo; BG and BH are the limits belonging to the blue; BH and BI the limits pertaining to the green; BI and BK the limits for the yellow; BK and BL the limits for the orange-coloured rays; and, lastly, BL and BC, those of the fines of refraction belonging to the red.

And particularly, when light passes out of glass into air, if the sine of its angle of incidence be 50, the sine of the angle of refraction of the red will be between $77\frac{1}{2}$ and $77\frac{1}{3}$, of the orange-coloured between $77\frac{1}{2}$ and $77\frac{1}{3}$, of the yellow between $77\frac{1}{2}$ and $77\frac{1}{3}$, of the green between $77\frac{1}{2}$ and $77\frac{1}{3}$, of the blue between $77\frac{1}{2}$ and $77\frac{1}{3}$, of the indigo between $77\frac{1}{2}$ and $77\frac{1}{3}$, and of the violet-coloured rays between $77\frac{1}{2}$ and 78.

To render this proof complete, we must now shew that these dispositions of the rays of light to produce some one colour, and some another, which manifest themselves after being refracted, are not wrought by any action of the prism upon them, but are originally inherent in those rays; and that the prism only affords each species on occasion of shewing its distinct quality, by separating them one from the other, which before, while they were blended together in the unrefracted light of the sun, lay concealed.

This will be proved by the following experiment. Things remaining as in the foregoing one, let another prism, as NO, (Plate XXXV. *fig. 4.*) be placed either close to, or at some distance from the first, in a perpendicular situation, with respect to the former, so that it may refract the rays issuing from the first, sideways. Now, if this prism could separate the light, which falls upon it into coloured rays, as the other did, it would divide the image breadthwise into colours, as before it was divided lengthwise; but no such thing is observable; for the image should only be thrown out of the perpendicular situation LM into the oblique one PQ; the upper parts, which were more refracted in the former case, being more refracted in this; and therefore made to reside farther sideways from their former situation L, than the lower ones are from M. And farther, each colour shall be uniform from side to side in the oblique image, as well as the perpendicular one.

If there be any objection against the sufficiency of this proof, it must be that the rays, when they fall upon the second prism, are not all in like circumstances with regard to their inclination to its surface; we shall therefore, to obviate that objection, add one more experiment, which seems to be peculiarly adapted to that purpose. It is as follows:

Two boards AB, CD, (Plate XXXV. *fig. 5.*) being erected in a darkened room at a proper distance, one of them AB being near the window-shutter EF, a space being only left for the prism GHI to

be placed between them; so that part of the rays, which enters the hole M, may, after passing through the prism, be transmitted through a smaller hole K, made in the board AB, and passing on from thence to go out at another hole L, made in the board CD, of the same size as the hole K, and small enough to transmit the rays of one colour only at a time. Let another prism PQR be placed behind the board CD to receive the rays passing through the holes K and L, and after refraction by that prism, let the rays fall upon the white surface ST. Suppose first the violet light to pass through the holes, and to be refracted by the prism PQR to *s*, which, if that prism were not there, would have passed on to W. If the prism GHI be turned about slowly, so that the incident ray ZY may fall more obliquely upon it, while the boards and the other prism remain fixed, in a little time another colour, suppose indigo, which we may suppose before to have proceeded to *s*, will pass through the holes K and L; and if the prism PQR were removed, would proceed like the former rays to the same point W. Now the refraction of this prism will not carry these rays to *s* as it did the other, but to some place less distant from W, as to *t*. But it is manifest, that the holes K and L being in the same situation in each case, both sorts of rays enter the prism PQR under the same circumstances, for they are equally inclined to its surface RP, and enter it at the same point thereof; which shews that the one species is more diverted out of its course by refraction, than the other is, when the circumstances of incidence are the same in each. Farther, if the prism GHI be turned about till the rays which exhibit blue, pass through the hole L, these will fall upon the surface ST below *t*, as at *u*, and therefore are subject to a less degree of refraction than such as produce indigo. And thus by proceeding, it will be found that the green is less refracted than the blue, and so of the remaining colours, according to the order in which they are represented in an image formed by a single prism. And also each species of rays is disposed to excite in us the idea of a different colour.

This is sufficiently clear from what has been already said, and is farther confirmed by what follows, viz. that whatever species of rays are thrown upon any body, they make that body appear of their own colour. Thus minium in red-light appears of its own colour; but in yellow-light it appears yellow; and in green-light, green; in blue, blue; and in violet-purple-coloured light it appears of a purple colour: in like manner verdigrise will put on the appearance of that colour in which it is placed. But each of these bodies appears most luminous and bright when enlightened with its own colour, and dimmest in such as are most remote from that.

It is certain therefore each ray is disposed to excite its own colour, which is neither to be altered by refraction nor reflection. Thus much in confirmation

of the first part of the proposition, viz. that there are different species of light, and that each species is disposed to suffer a different degree of refrangibility, and to excite in us the idea of a different colour. We proceed now to the second part of the proposition, viz.

2. That bodies appear of that colour which results from a composition of those colours which the several species they reflect are disposed to excite.

We have just now seen that each ray, whatever be the colour of the body it is reflected from, is able to excite no other idea than that of its own colour; and that coloured bodies reflect not all the different sorts of rays that fall upon them in equal plenty, but some sorts, viz. those of their own colour, much more copiously than others. We will now proceed to shew, that the other colours may be produced from a mixture of those seven, which rays of light, when separated by a prism, are disposed to exhibit. From whence it will be rational to conclude, the bodies appear of that colour which arises from the mixture of those which they reflect.

1. All the prismatic colours, viz. those that are made by the prism, mixed together, appear white, a little inclining to yellow, such as is that of the sun's light.

To shew this, let a convex lens be placed between the prism and the paper which receives the image, in order that the rays separated by it may be collected into a focus; and let this focus fall upon the paper, then will the spot where it falls appear white. And that the whiteness of this focal point is owing to the union of those colours appears from hence, that if we remove the paper from the focal point, and suffer the rays to cross each other in the focus, and if, when they have proceeded to some distance beyond, they be then received upon the paper, the same coloured image will be exhibited, and inverted, because the rays cross each other in the focus; an evident proof that the whiteness of the spot was owing to nothing but the mixture of the rays constituting the several colours of the image. But if the rays of any particular colour be intercepted before they are collected in the said spot, it then appears not only of a different colour from what it did before, but different from any of the prismatic colours taken separately. Or if the circumference of a wheel be painted with the prismatic colours taken in the same proportion with respect to each other, in which they are exhibited in the image made by the prism, and the wheel be turned swiftly about, the circumference of that wheel shall appear white: if they are taken in other proportions, the colour of the wheel, when turned about, will vary accordingly. From whence this part of the proposition is also abundantly clear.

No composition of these colours will produce black; that being no colour but the defect and absence

fence of all colour whatever. That species of light which is disposed to suffer a greater degree of refraction, requires proportionally less obliquity at the second surface of any medium to occasion a total reflection of it there; so that it is possible that a ray of light may pass through a medium with such obliquity, that only that part of it which is disposed to exhibit a violet colour shall be reflected at the second surface, and all the rest transmitted there. This indeed is a necessary consequence of what was observed concerning the reflection of light at the second surface of any medium, viz. that the reflection of a ray is total, when the obliquity of the incident ray is such, that the angle of refraction ought to be equal to, or exceed a right one. This is a consequence of that, because the angle of the refraction of the violet-coloured light is larger than the angle of refraction of any other, though their angles of incidence are equal. And accordingly thus it happens, as appears by the following experiment.

Let AB (Plate XXXV. fig. 6.) represent the window-shutter of a darkened room; C a hole to let in a ray of the sun; DEF, GHI, two prisms so applied together that the sides EF and GI be contiguous, and the sides DF and GH parallel: in this situation light will pass through them without any separation into colours; for the opposite sides being parallel, if the rays are refracted one way where they go in, they will be as much refracted the contrary way where they go out. But if it be afterwards received by a third prism KLM, will be divided so as to form upon any white body NOYU the usual colours, violet at *l*, indigo at *m*, blue at *n*, and red at *r*. Now let it be supposed that the surfaces EF and GI are not quite close together; but that the rays in passing from one to the other, pass through a medium (viz. the air) of different density from that of the prisms; and that the ray ZC is not so much inclined to the second surface of the first prism as to cause a total reflection of any one species there; then will part only of each species be reflected, and part transmitted.

Let now the reflected rays be received by a fourth prism TVX; these, after passing through it, will paint upon a white surface RS, the colours of the prism, viz. red at *s*, orange at *t*, yellow at *v*, and violet at *z*. Let now the prisms DEF, GHI, be slowly turned about, keeping still the same situation with respect to each other, until the obliquity of the rays ZC to the surface EF be so far increased, that there shall begin to be a total reflection of them there. In which case it is observable, that first of all the violet light will be totally reflected, and will therefore disappear at *l*, appearing instead thereof at *z*, and increasing the violet light which fell there before. And when the rays ZC become more oblique by the prisms being turned farther about, the indigo shall be totally reflected, disappearing at *m*, but falling upon *y*, and making the violet there

more intense: and by turning the prisms still farther about, all the remaining colours will be successively removed from the surface PQ to RS.

We are now to enquire what it is that gives bodies this power of reflection, some one sort of rays most copiously, and some another: and this is probably no other than the different magnitude of the particles whereof they are composed, as will appear from the following observations.

If water be prepared with soap so as to render it sufficiently tenacious, and then blown up into a bubble; it is observable, that as the bubble grows thinner and thinner, as it will do by reason of the water's continually running down from the top of it, till it breaks, different colours will arise one after another at the top of the bubble, spreading themselves into rings, and descending till they vanish at the bottom in the same order they arose at the top.

Thus in an experiment of this kind, tried by Sir Isaac Newton, the colours arose in this order; first red, then blue, to which succeeded red a second time, and blue immediately followed; after that red a third time, succeeded by blue; to which followed a fourth red, but succeeded by green; after this a more numerous order of colours, first red, then yellow, next green, and after that blue, and at last purple; then again red, yellow, green, blue, violet, followed each other; and the last order of colours that arose was red, yellow, white, blue; to which succeeded a dark spot that afforded scarce any light, though it was observed to cause some very obscure reflection, for the image of the sun or candle might be faintly discerned in it; and this last spot spread itself more and more till the bubble broke.

Now it is apparent that the only reason why these different colours succeeded each other at the top of the bubble, in the above-mentioned manner, was because its thickness in that part continually varied, till it broke. It remained therefore to examine what was the thickness of the bubble at the top, at the time it exhibited each particular colour: and this was effected by the following contrivance, viz. by taking the object glass of a long telescope, such having but a very small degree of convexity, and placing it upon a flat glass: these glasses, by reason of the convexity of the former, would touch but in one point, and the distance between them, where they did not touch, would be exceedingly small, but larger, the farther we consider it from the point of contact. Now water being put between these glasses, the same colours appeared as in the bubble, in the form of circles or rings surrounding the point where the glasses touched, which point appeared black like the top of the bubble when it is thinnest. Next to this spot lay a blue circle, and next without that a white one, and so on in the same but contrary order to that in which the colours arose on the top of the bubble.

Now

Now the distance between the glasses, that is, the thickness of the body of water between them, where it exhibited any one colour of a particular order, was equal to the thickness of the bubble at the time the same colour appeared upon it. For though the medium the light must pass through to come at the water is, in one case, glass, and in the other, air; that makes no difference in the species of the colour reflected from the water: for pieces of Mucovy glass, made thin enough to appear coloured, would have their colours faded, but not the species of them altered by being made wet with water: but it was found that transparent bodies of different density would not under the same thickness exhibit the same colours; for if the forementioned glasses were laid upon each other without any water between them, the air between them would then afford the same colours as the water, but more expanded; so that each ring had a larger diameter, though they bore all the same proportion to each other; so that the thickness of the air, proper to reflect each colour, was in the same proportion larger than the thickness of the water adapted to reflect the same.

Farther, all the light which is not reflected by the thin substances, whether of air or water contained between the glasses, is transmitted through them; for when viewed from the other side, they exhibit also coloured rings as before, but in a contrary order; for the middle spot, which in the other view appears black for want of reflecting light, now looks perfectly white; next without this spot the light appears tinged with a yellowish red; where the white appeared before, it now seems black, and so of the rest.

It is farther observable that the forementioned thin plates, whether of air or water, did not appear of the same colour when viewed obliquely, as when seen direct; for if the rings and colours between a convex and plain glass be viewed first in direct manner, and then under different degrees of obliquity, the rings will be observed to dilate themselves as increased. But a plate of air between the glass alters its colour much sooner than the water in the bubble, which is surrounded with air: for in the water, when viewed obliquely, the same colour might be seen at more than twelve times the thickness it appeared at under a direct view; but when the air was viewed under such an obliquity, that the thickness of the plate, where it was observed, was but half as much again as when it was viewed directly, a different colour appeared.

Lastly, the same colour reflected from a denser substance reduced to a thin plate, and surrounded by a rarer, will be more brisk than the same colour, when reflected from a thin plate formed of the rarer substance, and surrounded by the denser; as was found by blowing glass very thin, which exhibited in the open air more vivid colours than the air does between two glasses.

As to the thickness of the plate of air by which the several colours were reflected, it was found by carefully measuring the distances of the rings from the points where the glass is touched, that the distance between the glasses where the first order of colours was reflected, was from $\frac{1}{178000}$ to $\frac{1}{176000}$ part of an inch; that where the second, was from $\frac{1}{176000}$ to $\frac{1}{174000}$; that where the third, from $\frac{1}{174000}$ to $\frac{1}{172000}$, and so in a series of the odd numbers: and that the distance of the glasses, where the first order of colours that was transmitted passed through, was from 0 to $\frac{1}{178000}$ part of an inch; that where the second, was from $\frac{1}{178000}$ to $\frac{1}{176000}$; that where the third, from $\frac{1}{176000}$ to $\frac{1}{174000}$, and so on in a series of the even numbers. And the thickness of a plate of water, where it reflected or transmitted the same colours, was $\frac{3}{4}$ of the thickness of the plate of air.

Now we learn from experiments made with the microscope, that the least parts of almost all bodies are transparent; or the same may be experienced in the following manner: Take a very thin plate of the opaqueness body, and the room being darkened, apply it to a small hole in the window-shutter, and it will sufficiently discover its transparency. This experiment cannot be so well performed with a white body, because of the strong reflecting power in such; but even those, when dissolved in aquafortis or other proper menstrua, do also become transparent. Wherefore if we should suppose any body reduced to a thinness proper to produce any particular colour, and then broken into fragments, in all probability each fragment would exhibit that colour, and a heap of such fragments would constitute a body of that colour; so that the cause, why some bodies reflect one sort of rays most copiously, and some another, is probably no other than the different magnitude of their constituent particles.

This Sir Isaac Newton thinks a probable ground for making conjectures concerning the magnitude of the constituent particles of bodies. The green of vegetables he takes to be of the third order, as likewise the blue of the syrup of violets. The azure colour of the sky he thinks is of the first order, as also the most intense luminous white; but if it is less strong, he then conjectures it to be a mixture of the colours of all the orders. Of the latter sort he takes the colour of linen, paper, and such like substances to be; but white metals to be of the former sort. For producing black the particles must be smaller than for exhibiting any of the colours, viz. of a size answering to the thickness of the bubble where it reflected little or no light, and for that reason appeared colourless.

The colours in the same part of a peacock's tail vary as the tail changes its posture with respect to the eye; just so the thin plates of air or water appear of a different colour in the same plate when viewed directly, from what they do when seen obliquely.

as was observed above. The colours of silks, cloths, and other substances, which water or oil can intimately penetrate, become faint and dull by being wet with such fluids, and recover their brightness when dry; just as we observed that plates of Muffcovy glass grow faint and dim by wetting: all which particulars, and many more that might be produced, abundantly prove the present proposition.

COLOUR, in painting, is applied both to the drugs made use of in that art, and to the tints produced by those drugs variously mixed and applied.

Colours may be either pigments or fluids. By pigments is meant all such solid bodies as require to be mixed with some fluid, as a vehicle, before they can be used as paints, except in the case of crayons, where they are used dry. These make the far greater part of the whole; the fluid colours being only a small number employed along with water colours; and asphaltum, which is sometimes employed in oil-painting.

Colours are distinguished into several kinds, according to the vehicles in which they are worked, as oil-colours, water-colours, enamel-colours, &c. The same sorts of pigments, however, are, in many instances, employed in more than one kind of painting, as vermilion and lake in several, and ultramarine in all.

The principal qualities in colours, considered with regard to their perfection or faultiness, are two; purity of colour, and durability: purity of colour is, by the painters, called *brightness*, and the defect of it *fauiness*, or sometimes the breaking the colour: durability is called *standing*, and the negative, or want of it, *flying*, or flying off; which terms, for conciseness, we shall use in speaking of these qualities.

Brightness and standing well are the only properties which are necessary to the perfection of every kind of colours, and they equally relate to all; but there are others which are essential to many sorts, with regard only to particular purposes and uses.

The most considerable of the more general properties of colours, after purity and durability, or brightness and standing well, are transparency and opacity; for according to their condition, with respect to these qualities, they are fitted to answer very different kinds of purposes. Colours which become transparent in oil, such as lake, Prussian blue, and brown pink, are frequently used without the admixture of white, or any other opaque pigment; by which means the tint of the ground on which they are laid retains, in some degree, its force; and the real colour produced in the painting is the combined effects of both. This is called *glazing*, and the pigments endowed with such property of becoming transparent in oil, are called *glazing colours*. The same holds good also of such colours

as are transparent in water; only when they are there used in this manner, they are not called *glazing*, but *washing*, colours. When colours have no degree of such transparency in the vehicle in which they are used, as vermilion, king's yellow, and several others, they are said to have a body, and to cover. The property of glazing or washing is of so much importance, both in oil and water, that no other method can equally well produce the same effect in many cases, either with regard to the force, beauty, or softness of the colouring; and it is therefore very essential to the perfection of several kinds of pigments, that they should possess this property in a complete degree; but, in other instances, the using colours with a strong body is not less necessary, especially for the grounding or laying in, as it is called, of many objects to be painted.

There is another material quality in colours, that relates only to their use in oil, which is the drying well, and, as it is called, not fattening. By fattening is meant a coagulation of the oil, that frequently happens on its commixture with several kinds of pigments, by the effect they have upon it; from whence, after some time keeping, it is rendered so viscid or glutinous a consistence, as to be wholly incapable of being worked with either brush or pencil. This quality, when found in them, destroys almost wholly the value of such pigments for the purposes of the colourmen, who sell a great part of them ground in oil, and tied up in pieces of bladder, where they are kept till there is a demand for them, which frequently does not happen soon; and, therefore, gives time for their spoiling, in consequence of this quality. But to painters who mix the colours for themselves on their pallets with the oil, this property is not an equal inconvenience, when in a lesser degree; only, in general, it must be observed, that colours, in proportion to their tendency to fatten, are slow in drying; and when the oil once contracts this state, it will be a very long time before it will become duly hard and firm in the painting.

There are two other qualities of colour in general that relate only to their tint, or hue; but which render them, nevertheless, fit or improper, in a very material degree, for different purposes. They are distinguished by the names of *warmth* and *coolness*; terms which, indeed, are used very frequently by painters, but, for the most part, very indefinitely, and without any precise or clear meaning. What is meant, when properly used, by warmth, is that fiery effect which a small addition of yellow gives to a true red, and that glowing appearance which red imparts to either yellow or blue. By warmth, therefore, in red, is to be understood a small inclination towards orange; by the same term applied to yellow, a like tendency by the admixture of red; and by the same again, in the

case of blue, must be understood its slightly verging on the purple.

By coolness is to be understood the opposite to warmth; but this term is seldom used, except in speaking of yellow and blue; and there it means either the negation of that which causes warmth, or a tendency to green, in either colour, by a slight admixture of the other.

The sense of the word warmth, when applied to colouring, or the combined appearance of various tints, must not be confounded with that which it has when speaking of particular colours; for there it relates to the producing a strong effect by the disposition or contrast of the colours, or the grossness of the tints, and not the qualities peculiar to, or inherent in, the colours themselves.

The colours used in all the several kinds of painting, except some peculiar to enamel, are as follows:

Class I. Red—Vermilion, native cinnabar, red lead, scarlet oker, common Indian red, Spanish brown, terra de Sienna burnt; these are scarlet, or tending to the orange. Carmine, lake, rose-pink, red oker, Venetian red; these tend to the crimson, or to the purple.

Class II. Blue—Ultramarine, ultramarine ashes, Prussian blue, verditer, cendre blue, or sanders blue, indigo, smalt, bice, litmus, or lacmus.

Class III. Yellow—King's yellow, Naples yellow, yellow oker, Dutch pink, English pink, light pink, gamboge, masticot, common ochre, gallstone, terra de Sienna unburnt, turpith mineral, yellow berry wash, turmeric wash, tincture of saffron.

Class IV. Green—Verdigrise, distilled verdigrise, or crystals of verdigrise, Prussian green, terra vert, sap green.

Class V. Orange—Orange lake.

Class VI. Purple—True Indian red, archal, logwood wash.

Class VII. Brown—Brown pink, bistre, brown oker, umbre, Cologne earth, asphaltum, Spanish juice, or extract of liquorice.

Class VIII. White—White flake, white lead, calcined hartshorn, pearl white, troy-white, egg-shell white.

Class IX. Black—Lamp black, ivory black, blue black, Indian ink. See each under its proper article.

These are all the colours at present in use in this country, in any kind of painting, except such as are peculiar to enamel; in which kind of painting, as but few of these are capable of combining with glass, and enduring the necessary heat without changing their nature, or being destroyed, others are employed more suitable to vitrification: for which see the article *ENAMEL Painting*.

Theory of mixing of COLOURS. There are two things to be principally considered in regard to co-

lours; namely, the hue, (which is properly what may called the colour) and the strength of light and shadow: for as different colours, suppose red and green, may have the same strength of light, so two things, that are one of them much darker than the other, may still have the same hue as a light blue and a dark blue.

With respect to the hue, these two things are to be considered. 1^o. The species of colour, and 2^o. The perfection and imperfection of colour under the same species differ in degrees of perfection, as the red of a field poppy is much more perfect than the red of a brick. This quality of perfection and imperfection in the colours, by the painters, is expressed by the terms bright, or clean or simple, and broken, which is taken from their method of making the imperfect colours by the mixture of other colours, which is called breaking the colours. With respect to this quality of colours, Sir Isaac Newton, in his Treatise on Optics, shews that every ray of light has its proper colour, which it always carries with it, and never loses, in whatever manner it happens to be reflected or refracted. These natural colours of the rays are the bright simple colours, and the natural order of them, as they appear when they are separated by the refraction of a prism, is red, orange, yellow, green, blue, indigo, violet: all the less perfect or broken colours are made by the composition and mixture of these simple colours, as yellow rays mixed with blue rays make a green, but not so perfect as the simple natural rays that are green; and red and yellow rays make an orange colour, but not so perfect as the natural orange-coloured rays. And by a just proportion of all the natural rays together, is produced whiteness, which is indifferent to all the simple colours, and cannot be said to incline more to one colour than to another. By white is to be understood any colour between the lightest white and the darkest black; for as we are not now considering the degrees of light and shade, all the colours from black to white are to be considered as of the same hue.

According to this observation of the nature of whiteness, it appears that the broken colours are a medium between the simple colours and white; and the more broken a colour is, the nearer it is to white, and the further it is from white, the more simple it is.

Having thus explained the nature of the colours, and the effect of their mixture, in order to find exactly what colour will be produced by the mixture of any colours given, the colours are to be disposed in the following manner. Let there be a circle, as A D F A (Plate XXXV. fig. 7.) described, and let the circumference be divided into seven parts A B, B C, C D, D E, E F, F G, G A, in the same proportion to one another as the fractions $\frac{1}{2}$, $\frac{1}{3}$, $\frac{1}{4}$, $\frac{1}{5}$, $\frac{1}{6}$, $\frac{1}{7}$, $\frac{1}{8}$; which are the propor-

proportions of the musical notes *Sol, la, fa, sol, la, mi, fa, sol*. Between A and B place all the kinds of red, from B to C place all the kinds of orange, from C to D place all the kinds of yellow, from D to E place all the kinds of green, from E to F place all the kinds of blue, from F to G place all the kinds of indico, and from G to A place all the kinds of violet. Having thus disposed the simple colours, the center of the circle O will be the place of white. And between the center and the circumference are the places of all the broken compounded colours, those nearest the center being the most compounded, and those farthest from it being the least compounded: as in the line O 1, all the colours at 1, 2, 3, 4, are of the same species; that is, green inclining toward blue; but the colour at 1 is the simple natural colour; that at 2 is something compounded, or broken; that at 3 is more broken; and that at 4 is still more broken.

The colours being thus disposed, to know what colour results from the mixture of any colours given, find the center of gravity of the places of the colours given, and that will shew the character of the compound. For example, suppose it were required to know what colour would result from the mixture of two parts of the simple yellow at P, with three parts of the simple blue at Q; first find the center of gravity 3 of the points P and Q thus: draw P Q, and having divided it into five parts, (which is the sum of three and two) take the point 3 three parts from P, (because there are three parts of blue) and two parts from Q (because there are two parts of the colour at P); then draw O 3 cutting the circumference in 1, by the place of the point 1, (which is between D and E, but nearer to E) we find the mixture is a green inclining towards blue; but because 3 is near the middle between the center and the circumference, the colour is pretty much broken. To make the same thing more clear by another example; suppose I would know what would result from a mixture of two parts yellow at P, three parts blue at Q, and five parts red at R. First I find the place 3 of the mixture of the yellow and the blue, as before; then drawing the line 3 R (because there are five parts of the colour at 3, and five parts of the colour at R) I divide it into ten parts, and take the point *r* five parts distant from R. By this means *r* is the center of gravity of the three colours at P, Q, and R, and is consequently the place of the mixture; which by drawing O *r* cutting the circumference in 1, I find to be an orange a little inclining towards red; and because *r* is much nearer the center than the circumference, the colour is very much broken: and thus one may proceed in other cases.

Again, having given the place of any compound colour, one may find what colours may be mixed to compound it. Thus, having given the colour at 3, drawing any line P 3 Q through 3, the co-

lour proposed may be made by a mixture of the colours in P and Q, taking such a proportion of them as is expressed by the lines 3 P and 3 Q; that is, taking of the colour P as much as in proportion to 3 Q, and as much of the colour Q as is in proportion to 3 P; or having drawn O 3 passing through the points 1, 2, 4, the same colour may be produced by mixing the colours in 2 and 4, in proportion to the lines 4, 3, and 2, 3; or it may be produced by breaking the simple colour at 1, with white (which is at O) in the proportion of the lines 3, 1, and 3 O: and thus in other cases.

The proportions hitherto mentioned of the colours to be used in the mixtures, relate to the quantity of the rays of light, and not to the materials which artificial colours are made of. Wherefore if several artificial colours were to be mixed according to these rules, and some of them are darker than others, there must be a greater proportion used of the darker materials, to produce the hue proposed, because they reflect fewer rays of light in proportion to their quantities; and a lesser proportion must be used of the lighter materials, because they reflect a greater quantity of light.

If the nature of the material colours, which are used in painting, was so perfectly known, as that one could tell exactly what species of colour, how perfect, and what degree of light and shade each material has with respect to its quantity, by these rules one might exactly produce any colour proposed, by mixing the several materials in their just proportions. But though these particulars cannot be known to sufficient exactness for this purpose, besides the tediousness that would be in practice, to measure the colours according to their exact proportions; yet the knowledge of this theory may be of great use in painting. Suppose, for example, I had a pallet provided with the several colours at *a, b, c, d, e*; suppose for instance at *a*, carmine; at *b*, orpiment; at *c*, pink; at *d*, ultramarine; at *e*, smalts; and I had occasion to make a broken green, such as I judge should be placed at *x*. I see that it does not lie a great deal out of a line drawn through *c* and *d*; therefore I conclude, that mixing the colours *c* and *d* will come very near to what I want: but because *x* is nearer to the center O than the line *cd*, having brought my tint as near as I can to what I want, suppose to *z*, I look from *z* cross *x* for some colour opposite to *z*, to break the tint with, and I find the nearest to be *a*; therefore by mixing of the colour *a*, I bring the composition to the tint I have occasion for. If the colour *a* carries the tint too much towards the line O D, I put a little more of the colour *d*, which brings it into the right place: or having got the tint *z*, I might have broken it with white, whose place is at the center O: or putting a greater proportion of the colour *d*, instead of *a*, I may afterwards break the tint by means of the colour *b*. And in the same manner,

by only inspecting this scheme, one may see in what manner to make any tints whatsoever that can be produced by the colours that one uses. Thus one sees that red and yellow make a brown orange colour, which may still be more broken by adding blue, or indigo, or violet, which are to be taken one or other, as one would have the tint inclined more to the yellow or to the red, blue bringing it towards the yellow, and breaking it too much, and violet carrying it towards the red, and not breaking it so much.

From these principles one may see the reason why the materials of the brightest and simplest colours are the most valuable, and of them why the lightest are most to be esteemed. The simplest colours are the most valuable, because they cannot be produced by mixture; for mixture always breaks the colours: suppose *a, b, c, d, e*, to be all the colours you have, then drawing lines to join the points *a, b, c, d, e*, all the tints that can be produced by those colours will have their places within the area of the polygon *a, b, c, d, e*. That the lighter colours are more valuable than the dark ones, is because black does not break the colours so much as white; so that it is easier to make the clean dark tints with light colours and black, than to make the bright light ones with dark colours and white: for, by what has been shewed, white breaks the colours very much, but black, being nothing but the absence of light, only darkens the colours; though upon account of the imperfection of the materials that are in use, black does also break the colours something, because there is no material so perfectly black as to have no colour at all, as one sees by the best blacks having lights and shades. There will be other exceptions also to be made in the application of these observations to practice, upon account of the particular qualities of the materials some colours are made of. If all the colours were as dry powders, which have no effect upon one another, when mixed, these observations would exactly take place in the mixing of them: but some colours are of such a nature, that they produce a very different effect upon the mixture, to what one would expect from these principles: so that it is possible there may be some darker materials, which, when diluted with white, may produce cleaner and less compounded colours than they gave when single; as some colours do very well to glaze with, which do not look well when laid on in a body.

COLOUR, in heraldry. The colours generally used in heraldry are red, blue, black, green, and purple, which heralds call gules, azure, sable, vert, or sinople, and purpure. Tenne, or tawny, and sanguine, are not so common. As to yellow and white, called or and argent; they are metals, not colours. These metals and colours are sometimes also expressed in blazon by the names of precious stones, and sometimes by those of planets, or stars.

CENOMAUS is said to have first invented the distinction of colours, to distinguish the gundillæ of combatants of the Circenian games: the green for those who represented the earth; and the blue for those who represented the sea.

COLOUR, in law, is a probable or plausible plea, though really false in itself, and only calculated to draw the trial of the cause from the jury to the judge.

COLOURING, among painters, the manner of applying and conducting the colours of a picture; or the mixtures of light and shadows formed by the various colours employed in painting.

The colouring is one of the chief branches in painting, which art is, by Mr. Felibien, divided into three parts, the design, the composition, and the colouring. See the article **PAINTING**.

COLOURING and non-colouring Drugs. Into these dyers distinguish their ingredients: the first are applicative, and communicate their colours to the matters boiled in them, or passed through them, as wood, scarlet-grain, cochineal, indigo, madder, turmeric, &c.

The second serve to prepare and dispose the stuffs and other matters, and to extract the colour out of the colouring ingredients; as alum, salt or crystal of tartar, arsenic, realgal, salt-petre, common-salt, sal ammoniac, sal gemmæ, agaric, spirit of wine, bran, peas-flour, wheat, starch, lime, and ashes.

COLOURS, in the marine, certain banners or streamers which distinguish the ships or fleets of one nation from those of another; and the inferior divisions or squadrons of a fleet from each other. See the article **FLAG**.

A **SUIT OF COLOURS** for the admiral's ship consists of a flag, ensign, and jack; and those of a commodore or private ship of war with the two latter and a pendant. See the articles **ENSIGN**, **JACK**, and **PENDANT**.

COLOURS used in Dying. There are in the art of dying five colours, called simple, primary, or mother colours, from the mixture of which all other colours are formed; these are blue, red, yellow, brown, and black. Of these colours, variously mixed and combined, they form the following colours, pansy, blue, and red; from the mixture of blue and scarlet are formed amaranth, violet, and pansy; from the same mixture of blue, crimson, and red, are formed the columbine or dove colour, purple, crimson, amaranth, pansy, and crimson violet.

Here it is to be observed, that they give the name crimson to all colours made of cochineal.

Of blue and red madder is dyed purple, pepper colour, tan colour, and dry-rose colour.

The same blue, with red, half in grain, makes amaranth, tan colour, and dry-rose colour.

Blue and half-red crimson compose amaranth, tan colour, dry-rose, a brown pansy, and sun-brown.

Blue and yellow mixed together compose a yellow-green, spring-green, grafs-green, laurel-green, brown-green, dark-green; as well as sea-green, parrot-green, cabbage-green, &c. these three last colours are to be left boiled than the rest.

This is to be noted, that as to green there is no ingredient or drug in nature that will dye it, but the stuffs are dyed twice, first in blue, then in yellow.

Blue and brown. These two colours are never mixed alone; but with the addition of red, either of madder or cochineal, they form several colours.

Red and yellow. All the shades composed of these two colours, as gold-yellow, aurora, mary-gold, orange, nacarati, granat-flower, flame colour, &c. are made with yellow and red of madder; scarlet being less proper as well as too dear.

Red and brown. Of these two colours are formed cinnamon colour, chestnut, musk, bears-hair, and even purple, if the red be that of madder.

Yellow and brown. The colours formed from these two are all the shades of feuille-mort and hair colours.

But this may be taken notice of, that though it be said that there are no colours or shades made from such and such mixtures, it is not meant that none can be made, but that they are more easily formed from a mixture of other colours.

COLT, in zoology, the same with foal, being the young of the horse-kind. See **FOAL**.

COLT-EVIL, among farriers, a swelling of the yard and cods, incident both to stoned horses and geldings; for which, after washing the part with luke-warm vinegar, it is usual to anoint them with juice of rue; mixed with honey, and boiled in hog's grease, adding bay-leaves and the powder of fenugreek.

COLT'S FOOT, in botany, the English name of the tussilago. See **TUSSILAGO**.

COLTIE, a term used by timber-merchants for a defect, or blemish, in some of the annular circles of a tree, whereby its value is much diminished.

COLUBRINUM LIGNUM, snake-wood. See **NUX VOMICA**.

COLUMBINE, *Aquilegia*, in botany. See the article **AQUILEGIA**.

COLUMBINE-Colour, or dove-colour, among painters, denotes a kind of violet.

COLUMBUS, or *Congregation of St. COLUMBUS*, a society of regular canons, who formerly had an hundred abbeys or monasteries in the British islands.

COLUMN, in architecture, a round pillar, made to support and adorn a building, and composed of a base, a shaft, and a capital. As every fulcrum is so much the more perfect, as it is firm, or carries the appearance of firmness; hence all columns ought to have their base broader than themselves. See the article **BASE**.

And as a cylinder and a quadrangular prism are

more easily removed out of their place than a truncated cone, or a pyramid on the same base, and of the same altitude, the figure of columns ought not to be cylindrical, but grow less and less, like a truncated cone. Again, as columns are more firm if their diameter bears a greater proportion to their height than if it bore a less, the greater ratio is to be chosen where a large weight is to be sustained; and less, where a small weight is to be supported. Further, as the design of a column is to support a weight, it must never be supposed without an entablature.

Columns are different in the different orders of architecture, and may be considered with regard to their matter, construction, form, disposition, and use. With respect to the order, we have

Tuscan COLUMN, that which has seven diameters in height, and is the shortest and most simple of all the columns.

Its diminution is one fourth; that is, the diameter at top is three fourths of the diameter just above the base.

Doric COLUMN has eight diameters in height, and its capital and base more enriched with mouldings than the Tuscan. It diminishes one fifth part of the diameter at the base.

Ionic COLUMN has nine diameters in height, and differs from the others by the volutes in its capital, and by its base.

Corinthian COLUMN, the richest and most delicate of all, has ten diameters in height, and its capital adorned with two rows of leaves with caulicoles, from whence spring small volutes. It diminishes one seventh part of the diameter.

Composite COLUMN has likewise ten diameters in height, and two rows of leaves in its capital, with angular volutes like the Ionic. It diminishes one eighth part of the diameter of the base.

It may be observed, that different authors give different heights and proportions to columns of the same order, and that frequently the same author takes the liberty of dispensing with his own rules; but the heights and proportions exhibited above are a mean between the extremes of all the rest.

COLUMNS with regard to their Matter, are:

Fusible COLUMN comprehends not only columns of various metals, and other fusible matter, as glass, &c. but also those of stone, said to be cast, the secret of which some believe to have been known to the ancients.

Hydraulic COLUMN, the whole shafts appear to be of crystal; being formed by a number of little threads of water, falling from holes made in a girt of metal, at equal distances, by means of a pipe mounting through the middle of it. It also denotes a column from whose top proceeds a jet d'eau, to which the capital serves as a basin, whence the water descends by a little pipe, which turns spirally round the shaft.

Moulded

Moulded COLUMN, that made by impastation of gravel and flints of divers colours, bound together with a cement.

Water COLUMN, that whose shaft is formed of a large jet d'eau, which spouting out water violently from the base, drives it within the tambour of the capital, which is hollow, and in falling down it resembles a column of liquid crystal.

COLUMNS, with regard to their Construction.

Cabled or Rudented COLUMN, that having projections in form of cables, in the naked of the shaft, each cable having an effect opposite to that of a fluting, and accompanied with a little list on each side.

Colossal COLUMN, one of so large a size as not to enter any ordinance of architecture, but designed to be placed solitary in the middle of a square, &c. Such is the Trajan column.

Corollatic COLUMN, that adorned with foliage, turned spirally round the shaft, or in form of crowns and festoons: they are very proper for decorations of theatres.

Diminished COLUMN, that which has no swelling, but begins to taper from the base, in imitation of trees.

Geminated COLUMN, that whose shaft is formed of three similar and equal sides or ribs of stone, fitted within one another, and fastened at bottom with iron pins, and at top with cramp-irons: it ought to be fluted, that the joints may be less discernible.

COLUMN of Joinery, that made of strong timber-boards joined together: it is hollow, turned in the lathe, and usually fluted: such are the columns of most altar-pieces.

COLUMN of Masonry is made of rough stone, well laid and covered with plaster; or of bricks, laid triangular-wise, and covered with stucco.

COLUMN of Tambours, or Bands, that whose shaft is formed of several courses of stone, or blocks of marble, less high than the diameter of the column.

COLUMN in Truncheons, or Pieces, consists of two, three, or four pieces of stone or metal, differing from the tambours, as being higher than the diameter of the column.

COLUMNS with regard to their Form, are:

Fluted COLUMNS, called also channelled and fluted columns, those whose shafts are adorned with flutes or channellings, either from top to bottom, or only two thirds of their height.

Gothic COLUMN, a round pillar, either too short for its bulk, or too slender for its height, having sometimes twenty diameters, without either diminution or swelling, consequently differing widely from the proportions of the antique.

Hermetic COLUMN, a kind of pilaster, in manner of a terme, having the head of a man in lieu of a

capital. It is so called because the ancients placed on the top of such columns the head of Mercury.

Massive COLUMN, one too short for the order, the capital of which it bears: it likewise comprehends Tuscan and Rustic columns.

Oval COLUMN, that whose shaft has a flatness, its plan being made oval, to reduce the projection.

Pastoral COLUMN, that whose shaft is formed in imitation of a trunk of a tree, with bark and knots. It may be used in the gates of parks and gardens, and in the decoration of pastoral scenes.

Serpentine COLUMN, that formed of three serpents twisted together, the heads of which serve as a capital: it is now called the talisman, or enchanted column.

Swelled COLUMN, that which has a bulging in proportion to the height of the shaft. This practice obtains among the modern architects, but seems to have been unknown to the ancients.

Twisted COLUMN, that whose shaft is twisted round in form of a screw, with six circumvolutions, being ordinarily of the Corinthian order. Sometimes the twisted column is in form of two or three slender shafts twisted round, so as to leave a cavity in the middle.

COLUMNS, with regard to their Disposition.

Angular COLUMN is an insulated one, placed in the corner of a portico, or inserted in the corner of a building, or even a column that flanks any angle of a polygon.

Attic COLUMN, according to Pliny, is an insulated pilaster, having four equal faces, and of the highest proportion.

Cantoned COLUMNS are those engraved in the four corners of a square pillar, to support four springs of an arch.

Coupled COLUMNS, those disposed two and two, so as almost to touch each other at their bases and capitals.

Doubled COLUMN, one column joined with another in such a manner that the two shafts penetrate each other with a third of their diameter.

Engaged COLUMN, that which enters in a wall with one third or one fourth of its diameter.

Grouped COLUMNS, those placed on the same pedestal or socle, either by three and three, or four and four.

Insulated COLUMN, one standing free and detached from every other body.

Medium COLUMNS, a name given by Vitruvius to the two columns in the middle of a porch, which have their intercolumniation larger than the rest. The term may also be applied to the middle row of columns in a frontispiece adorned with three orders.

Niche COLUMN, that whose shaft enters with half its diameter into a wall, hollowed out for its reception.

reception with its plane parallel to the projecture of the torse.

COLUMNS, with regard to their Use, are either, 1st. Astronomical columns, such as that at Paris, erected for astronomical observations. 2. Chronological column. 3. Funeral column, which generally bears an urn, and has its shaft overspread with symbols of grief and of immortality. 4. Gnomonic column, a cylinder, upon which the hour of the day is represented by the shadow of a style: of these there are two kinds; in the one the stile is fixed, and the hour-lines are no more than the projection of a vertical dial upon a cylindrical surface: in the other the stile is moveable, and the hour-lines are drawn to the different heights of the sun in the different seasons of the year. 5. Historical column, that whose shaft is adorned with a basso relievo, running in a spiral line its whole height, and containing the history of some great personage. 6. Hollow column, that which has a spiral stair-case within-side, for the conveniency of ascending to the top. 7. Indicative column, that which serves to shew the tides along the sea-coasts. 8. Instructive column, that which conveys some precept or instruction, such as that raised by the son of Pisistratus at Athens, containing the rules of agriculture. 9. Itinerary column, one with several faces, placed in the crossing of several roads, serving to shew the different routes by the inscriptions engraved on its several faces. 10. Lactary column, at Rome, a column, according to Festus, in the herb-market, in the pedestal of which was a cavity, wherein young children, abandoned by their parents, through poverty or inhumanity, were exposed to be educated at the expence of the public. 11. Legal column, among the Lacedæmonians, that erected in a public place, upon which were engraven the fundamental laws of the state. 12. Limitrophous, or boundary column, that which shews the limits of a kingdom, or country, conquered. Those called the Columns, or Pillars of Hercules, are two very steep mountains, in the Straights of Gibraltar. 13. Luminous column, one formed in a cylindrical frame, mounted and covered over with oiled paper or gauze, so that lights being disposed in ranks within over each other, the whole appears to be on fire. 14. Manubriary column, a column adorned with trophies, built in imitation of trees, whereon the spoils of enemies were anciently hung. 15. Memorial column, that raised on occasion of any remarkable event, as the Monument in London, built to perpetuate the memory of the burning of that city in 1666. 16. Menian column, any column that supports a balcony, or meniana. 17. Military column, a column of marble, raised, by order of Augustus, in the middle of the Roman forum, from whence, as a center, the distances of the several cities of the empire were reckoned by other military columns, disposed at equal distances on all the grand roads. 18. Rostral column, that

adorned with the beaks, or prows of ships, &c. erected either in memory of a naval victory, or in honour of some admiral, &c. 19. Statuary column, that which supports a statue. 20. Symbolical column, that representing by symbols some particular country, or some memorable action. 21. Triumphal column, that erected by the antients in honour of an hero; the joints of the stones or courses of which were covered with as many crowns as he had made military expeditions. 22. Zoophoric column, a kind of statuary column, bearing the figure of some animal.

Scenography of a COLUMN. See the article SCENOGRAPHY.

COLUMN, among printers, is half a page, when the page is divided into two parts from top to bottom.

COLUMN, in the military art, a long deep file of troops or baggage.

The first and second lines of an army, as they are encamped, make generally two columns on a march, filing off either to the right or left: sometimes the army marches in four, six, or eight columns, according as the ground will allow; and each column is led by a general officer.

COLUMNS of a fleet or squadron. See the article LINES, SAILING.

COLUMNA, in anatomy, a term applied to different parts: thus the *columna nasi* is the lowest and fleshy part of the nose, which forms a part of the septum; and the *columna oris* is the same with the uvula. See SEPTUM and UVULA.

The *columnæ cordis* are small, long, and round fleshy productions in the ventricles of the heart. See HEART.

COLUMNÆA, in botany, a plant with a climbing stalk, the leaves are oval, serrated on their edges, and stand upon short foot-stalks; these, as also the stalks are very hairy. The flower is monopetalous and ringent, with four stamina, two being longer than the others. The fruit is an ovated bilocular capsule, containing a number of small, oblong seeds.

This plant, being a native of the warmest parts of America, requires a hot-house in this climate for their preservation.

COLURES, in astronomy and geography, two great circles supposed to intersect each other at right angles, in the poles of the world, and to pass through the solstitial and equinoctial points of the ecliptic.

That which passes through the two equinoctial points is called the equinoctial colure, and determines the equinoxes; and the other, which passes through the poles of the ecliptic, is called the solstitial colure, because it determines the solstices. See EQUINOX and SOLSTICE.

COLUTEA, bladder-fena, in botany, a genus of plants producing papilionaceous flowers. The

common sort is a shrub, which grows naturally in Aultria, in the south of France and Italy, from whence the seeds were originally brought to England. This plant hath several woody stems, which grow to the height of ten or twelve feet, sending out many branches, which are furnished with winged leaves, composed of four or five pair of oval leaves placed opposite, and terminated with an odd one; these are indented at the top, and are of a grayish colour. The flowers come out from the wings of the leaves on slender foot-stalks, about two inches long; each sustaining two or three flowers of the butterfly kind; these are yellow, with a dark coloured mark on each petal; they are succeeded by inflated pods an inch and a half long, having a seam on the upper side, containing a single row of kidney-shaped seeds.

This flowers in June or July, and the seeds ripen in autumn; they are propagated by seeds, and are very common in shrubberies, &c.

COMA, or COMA-VIGIL, a preternatural propensity to sleep, when, nevertheless, the patient does not sleep, or, if he does, awakes immediately, without any relief. This disorder is always symptomatic, and often attends acute, burning, and malignant fevers; as also an inflammation of the dura mater, and others in a phrenzy. Sometimes it attends a hemiplegia.

For the cure of the coma-vigil, if the fever has not continued above the third or fourth day, it is expedient to take away a large quantity of blood; then the body, if collicive, must be opened with clysters, which must not be very acrid; afterwards diluters and refrigerants must be given to moderate the febrile heat, such as absorbent powders, gentle nitrous medicines, taken in a draught with diaphoretic antimony, &c.

COMARUM, marsh cinquefoil, in botany, a plant whose flower consists of five oblong, acuminate petals, three times less than the cup in which they are inserted, with twenty subulated, permanent filaments, topped with lunular, deciduous antheræ; it has no pericarpium, but a scrotiform, fleshy receptacle, which is large and persistent, and contains numerous acuminate seeds. This plant grows wild in boggy places in divers parts of England.

COMA SOMNOLENTUM is when the patient continues in a profound sleep, and when awaked, immediately relapses, without being able to keep open his eyes. This is a primary disease, and must have a cause which obstructs the passage of the nervous fluid from the cortical part of the brain to the medulla oblongata, throughout the whole brain.

A coma somnolentum is divided into ferous and sanguine. The first requires the natural ferous evacuations to be restored or promoted; gouty fits are to be invited. Sternutatories are also of great use, as they discharge the serum through the nose, and

stimulate the nerves: and when a viscid phlegm offends the stomach, vomits are useful, with powder of squills, or emetic tartar, with a laxative potion. In a sanguine coma somnolentum, when the blood circulates slowly, or stagnates in the head, as in hypochondriac and scorbutic cases, all hot spirituous remedies are as bad as poison; but bleeding, clysters, gentle laxatives, cooling and nervous powders, are useful.

COMA BERENICES, in astronomy, a constellation of the northern hemisphere, situated between Virgo, Bootes, Canes venaticæ, and near the Lion's tail; this constellation comprehends, according to Ptolemy's catalogue three stars; Tycho's thirteen, and in the following forty-three. Catullus tells us in a Latin poem, that this is the Hair of Berenice, the wife of king Evergetes, who vowed to cut off her hair if her husband returned home from the war victor; which accordingly she did, and sent it to the temple of Venus, from whence it was said to be taken up into heaven and made a constellation.

COMB, an instrument to clean, untangle, and dress flax, wool, hair, &c.

Combs for wool are prohibited to be imported into Britain.

COMB is also the crest, or red fleshy tuft, growing upon a cock's head.

Lady's COMB, or *Venus's comb*, in botany, the same with the scandix. See the article **SCANDIX**.

COMBAT, in a general sense, denotes an engagement, or a difference decided by way of arms.

COMBAT, in our ancient law, was a formal trial of some doubtful cause or quarrel by the swords or battons of two champions. This form of proceeding was very frequent, not only in criminal, but in civil causes; being built on a presumption that God would never grant the victory but to him who had the best right. The last trial of this kind in England, was between Donald lord Ray, appellant, and David Ramsay, Esq. defendant; when, after many formalities, the matter was referred to the king's pleasure.

COMBATANT, in heraldry, a term for two beasts, as lions, &c. borne in a coat of arms, in a fighting posture, with their faces to each other.

COMBINATION is properly understood of an assemblage of several things by two and two; but is more particularly used in mathematics, to denote the variation or alternation of any number of quantities, letters, sounds, or the like, in all the different manners possible.

P. Merenne gives us the combinations of all the notes and sounds in music, as far as 64; the sum whereof amounts to 90 figures, or places.

The number of possible combinations of the 24 letters of the alphabet, taken first two by two, then three by three, &c. according to Mr. Prestet's calculation, amount to 139172428887252999425128493402200.

F. Truchet, in the Memoirs of the French Academy, shews, that two square pieces, each divided diagonally into two colours, may be arranged and combined sixty-four different ways, so as to form

so many different kinds of chequer-work; which appears very surprising, when we consider that two letters, or figures, can only be combined twice.

Problem 1. Any number of quantities being given, together with the number in each combination, to find the number of combinations.

One quantity, we observe, admits of no combination; two, a and b , of one; of three, abc , there are three combinations, viz. ab, ac, bc ; of four, six, ab, ac, bc, ad, bd, cd ; of five, ten, $ab, ac, bc, ad, bd, cd, ae, be, ce, de$; whence it appears that the number of combinations proceed as 1, 3, 6, 10, 15, &c. wherein, if we have n for the number of terms or quantities to be combined, we

shall have $\frac{n}{1} \times \frac{n-1}{2}$ for all the different pairs that

can be taken in the number of quantities n . If the proposed combinations are to be taken three by

three, $\frac{n}{1} \times \frac{n-1}{2} \times \frac{n-2}{3}$ will express the number of

combinations sought: but if they are to be taken by

four, $\frac{n}{1} \times \frac{n-1}{2} \times \frac{n-2}{3} \times \frac{n-3}{4}$ will be the answer;

and universally, if p be put for the number of quantities to be taken each time, then will $\frac{n}{1} \times \frac{n-1}{2} \times$

$\frac{n-2}{3} \times \frac{n-3}{4} \times \frac{n-4}{5}$, &c. continued to p terms, represent the number of combinations of p things in n .

Example. Let the number of quantities to be combined be 8, and 4 the number of them to be taken; then by expounding n by 8, and p by 4, we shall have $8 \times \frac{7}{2} \times \frac{6}{3} \times \frac{5}{4}$, or 70, for the number of combinations required.

The number of all the possible combinations, beginning from the combinations of every two, will, by writing successively for p the numbers 2, 3, 4, 5,

&c. be $\frac{n}{1} \times \frac{n-1}{2} + \frac{n}{1} \times \frac{n-1}{2} \times \frac{n-2}{3} + \frac{n}{1} \times \frac{n-1}{2}$

$\times \frac{n-2}{3} \times \frac{n-3}{4}$, &c. which is well known to be the

sum of the unciæ of the binomial $1 + 1$, raised to the n power, and abridged of the exponent of the power increased by unity $n + 1$; therefore the number of all the possible combinations will be expressed by $2^n - n - 1$.

Problem 2. Any number of quantities being given, to find the number of changes and alterations which those quantities, combined in all the manners possible, can undergo.

Suppose two quantities, a and b ; their variations will be 2: consequently as each of those may be combined, even with itself, to these there must be added two variations. The whole number, therefore, will be $2 + 2 = 4$. If there were three quantities, and the exponent of the variation were 2, the combination will be 3, and the changes 9; to which

which if the three combinations of each quantity with itself, aa, bb, cc , be added, we shall have the number of changes $3+3+3=9$. In like manner it is evident, if the given quantities were 4, and the exponent 2, the number of changes would be 16; if 5, 25, &c. and, in general, if n, n^2 .

Suppose the quantities 3, and the exponent of variation 3; the number of changes is found $27 = 3^3$; viz. $aaa, aab, aba, baa, abb, bac, aba, abc, bac, bca, abb, cab, cba, acc, cac, cca, bba, bab, bbb, bbc, cbb, bcb, bcc, cbc, ccb, ccc$.

After the same manner it will appear, that if the quantities were 4, and the exponent 3, the number of changes would be $64 = 4^3$: and, in general, if the number of quantities be $= n$, and the exponent 3, the number of changes will be n^3 . By thus proceeding, it will be found, that if the number of quantities be n , and the exponent n , the number of changes will be n^n ; wherefore, if all the antecedents be added, where the exponent is less, the number of possible changes will be found $n^n + n^{n-1} + n^{n-2} + n^{n-3} + n^{n-4} + n^{n-5} + n^{n-6}$, &c. till at length, the number subtracted from n leaves 1, because the beginning is from single quantities taken once.

Since then the number of possible changes is in a geometrical progression, whose first term is n , the greatest n^n , and the ratio n , it follows that $\frac{n^n + 1 - n}{n - 1}$ will express the number of possible changes. Sup-

pose v. gr. $n = 4$, then $\frac{4^n + 1 - n}{n - 1}$ will be equal to 340. Suppose again, $n = 24$, the number of possible changes will be 1391724288887252999425128493402200. In so many various manners, therefore, may the twenty-four letters of the alphabet be varied and combined among themselves.

COMBINATORY, in general, denotes something belonging to combination. See the preceding article.

COMBINATORY *Distillation*, a method of rectifying spirits, much practised by distillers, by distilling several ingredients along with the spirits; such are alkaline salts, and spirits, and other saline bodies capable of giving the spirits a good flavour. This method is condemned by Dr. Shaw, because these ingredients mix themselves so intimately with the spirits, as not to be easily separated again: hence, instead of rectifying or improving, they prevent the true and genuine taste of the spirits.

COMBUST, an appellation given to a planet when in conjunction with, or not distant above eight degrees and thirty minutes from the sun: some restrain the term combust to the distance of half their disk.

COMEDY, is a sort of dramatic poetry, which gives a view of common and private life, recom-

mends virtue, and exposes the vices and follies of mankind in an humorous and merry way. Scalliger defines comedy a dramatic poem, representing the business of life, whose event is fortunate and still familiar. Vossius defines it a dramatic poem, copying the actions of the principal citizens and common people in a familiar style, and not without mirth and railery.

COMET, an opaque, spherical and solid body like a planet, performing revolutions round the sun in elliptical orbits, which have the sun in one of the foci. The particulars in which they differ from the planets, are that they move in various directions, some the same way with the planets, others the contrary: neither are their motions confined within the zodiac, their orbits admitting of any inclination to the ecliptic whatever; and the eccentricity of their orbits is so very great, that some of the comets perform the greatest part of their motion almost in right lines, tending in their approach to the sun almost directly towards it, after which they pass by it; and when they leave it march off again nearly in a right-line, till they are invisible.

Though the ancients knew little of the use of conic sections, in comparison of what has been discovered within these last hundred and fifty years, yet they applied themselves to the study of their properties, and thereby prepared the way for the reader applying them to the uses lately found out. If those who at that time employed themselves in making astronomical observations, had been as careful in attending to the motion of comets, which do not require such depth of thought as abstruse mathematical problems; though they knew too little then of the principles of motion to have found out their real path, yet probably we should not have been so much at a loss, as we still are, as to their periods; but, by comparing their motions in different returns, even though the observations had been but gross, might have arrived to a considerable perfection in the astronomy of comets. But as most of their periods seem to be very long, and it is but a little while that their motions have been carefully watched, it may be some ages yet, before we get any great knowledge about them. Most of the ancients, being of Aristotle's opinion, that comets were only inflamed vapours, raised, continuing, and dispersed in our atmosphere, took little further notice of them than as omens, often mentioning neither the time of year, or place they were seen in; and unless both are known, we can neither find their orbit, nor compare them with that of any known comet. Seneca indeed, and some others whom he mentions, believed comets to be lasting heavenly bodies, Nat. Quæst. VII. 3 & 22: that multitudes of them, which could not be seen on account of their position, kept on their stated courses, and at certain times, when they got to the nearest end of their path, came within sight of men.

chap. 13, 17, 19. and he expected that time and pains would discover what was then unknown, and posterity wonder that they did not know such plain things, chap. 25. In these several places there is a better guess about comets, than any made for above fifteen hundred years afterward : and further search has since confirmed what he thought, that it is the eccentricity of their orbits which occasions their being only now and then seen. In all those dark ages, from the decline of the Roman empire to the reformation, comets being only considered as ominous meteors, three only have been yet found described enough to determine their orbits, and those but in a gross manner : and I think Appian was the first, who, about 1530, began to observe their motion astronomically ; and soon found that, so far from being within our air, they, having no sensible parallax, must needs be much further off than the moon : here then is the first step toward finding out the true nature of comets ; and from that time all astronomers have allowed their place to be among the planetary orbits, and many observations were made of their motions by Tycho Brahe and others.

The two comets of 1664 and 65, coming within a few months of one another, made many persons very inquisitive about them ; and in Birch's history of the Royal Society, vol. II. there are two remarkable guesses, both read May 23, 1666. In page 93, are Mr. Hooke's remarks on Mons. Petit's dissertation on the nature of comets, presented to the Society some weeks before. What that paper contained does not fully appear ; but Mr. Hooke said, the hypotheses were very ingenious, and some of them not improbable, but whether the comets were moved in equal spaces of a curve line in equal spaces of time, which Mons. Petit seemed inclined to believe, deserved to be further examined. This last clause is remarkable, and that paper, if still preserved, is worth searching, to see how near Mons. Petit was to guessing the truth. The other paper, page 91, is Mr. Hooke's own, endeavouring to account for the planet's motions ; where, having proposed the resistance of the æther, he says, the second cause of infecting a direct motion into a curve may be from an attractive property of the body placed in the center, whereby it continually endeavours to attract or draw it to itself : for if such a principle be supposed, all the phenomena of the planets seem possible to be explained, by the common principle of mechanick motions ; and possibly the prosecuting this speculation may give us a true hypothesis of their motions. By this hypothesis the phenomena of the comets as well as of the planets may be solved, and the motion of the secondary as well as their primary planets : the motion also of the progression of the æges is very evident. This I think was much about the time that Sir Isaac Newton discovered the property of gravity, and seems much like it ; only Sir Isaac, being the deeper mathema-

tician, prosecuted the matter further, and cleared it up more fully.

Hevelius was too good an astronomer, not to see that comets were far distant from the earth, and in his *Cometographia*, Book III. p. 149—164, largely shews the absurdity not only of supposing them in our air, but even below the moon, from the vast parallax they would have, and the various places they must needs be seen in at different times of day, as they rise towards the zenith, or descend to the horizon : yet could he not shake off the established opinion that they were meteors ; but, to reconcile both, supposes comets to be vapours collected near any of the planets, whirling round about it till thrown out of the atmosphere, and then moving in a straight or curve line till dispersed, Book VII. p. 384 ; that comets are not spherical, but round and flat, p. 338 ; and, from the time they leave the planet's atmosphere, always turn one flat side toward the sun, p. 666 ; and though, Book IX. p. 591—632, he calculates the places of several comets, as if moving in a straight line, and generally comes nearer the observed place, than I should expect such an hypothesis to do ; yet he thinks that their course is not really straight, p. 588 ; and in more largely treating on the subject, says, it is a parabola, p. 659. It may surprize those who have not read Hevelius, to hear that he first said a comet's orbit is parabolical, a discovery generally attributed to Sir Isaac Newton ; and indeed not without reason, for Hevelius did but guess it, and knew not the principle on which its motion depended ; but it was Sir Isaac Newton who first proved it, and accounted for its motion in that curve, from that universal principle of gravity, on which the motion of all the heavenly bodies depend. We may however give Hevelius his due praise as a good astronomer, and by a short extract from his *Cometographia*, Book IX. shew how nearly he guessed at the true motion of comets, without knowing, or even suspecting, the real cause which kept them in such a trajectory. A comet then, he says, “ by no means moves in a straight line, but in a curve, always concave toward the sun,” p. 658, that is, “ in a parabola,” p. 659 : this he illustrates by “ the parabolic motion of projectiles,” p. 660. He seems here to be got very near the point, yet shews afterward he did not think of gravity as the cause of a comet's parabola : for “ as projectiles move in a parabola, from a compound of their progressive motion and gravity, so comets also have a double motion ; one the force given them at leaving the planet's atmosphere, the other not gravity, yet something not unlike it, by which comets turn one of their flat sides toward the sun, as the center of our system, p. 666, as a magnetic needle points toward the north, or toward a loadstone. And as, in projectiles gravity, so in comets the inclination of their flat sides, turns them out of their straight course.”

"course," as a rudder turns about a ship, which he had before largely considered, p. 570—587. "And the farther a comet gets from the sun, the more will its flat side be opposed to its motion, which will not only more and more retard its swiftness, but turn it out of its straight course, p. 667. "But a comet differs from a projectile, in that a body thrown up moves slowest at the vertex of its parabola, and swifter both in rising and falling; while a comet moves swiftest at the vertex, where a line from the sun is perpendicular to its path, and slower both in approaching the sun and retiring from it, p. 669. If you ask whether a comet's path is not an hyperbola," he "will not deny it: it is neither circle nor ellipsis, but may be any other section of a cone, which is most bent in the middle, and straighter at each end: yet is satisfied it is rather a parabola than an hyperbola," p. 683. Lastly, "as the planets regard the sun as their center, so the comets also obey it in their way," p. 701. We see here that Hevelius, whether by a mere guess at what he thought must needs follow from his notion of comets being flat bodies, generally standing oblique to the path they move in, or finding such a motion to agree best with his observations, came very near to what has since been found to be the truth: that comets move in a parabola, concave toward the sun, swiftest at the vertex, that is, when they are nearest the sun, and their motion perpendicular to a line from it, and that it is an action of the sun on comets which makes them turn out of a straight line into a curved trajectory. So far he is right, and seems got near the point, but is defective in not suspecting the sun to be the parabola's focus, expressly denying their moving in an ellipsis, and consequently returning again; and the doctrine of gravity being a later discovery, he is forced to account for their curve another way. We may learn also from his book, that studies, of which we do not at first see the benefit, are not therefore always useless. Hevelius made many observations and calculations of the motion of comets; on which if a person at that time had said to him, *cui bona?* why so much time and pains spent on vapours, which were collected yesterday, and will be dispersed to-morrow? he, owing them to be nothing else, could not perhaps have given any sufficient reason for it: yet if he and others had not taken that pains, Sir Isaac Newton would hardly have found out their real motion; and there is a field yet open for further discoveries of future ages about them.

Sir Isaac Newton having discovered that gravity is universal, and that a planet whose velocity was in a due proportion to its gravity toward the sun, would revolve about it in a perfect circle; but in an ellipsis, of which the sun is one focus, if its motion was either faster or slower; on reconsidering the matter, on occasion of that remarkable comet of 1680, he

found, that, if a body is thrown with a velocity, which is to that necessary to keep it in a circle, as the square root of 2 to 1; the same universal principle of gravity will make it move in a parabola, of which the sun is the focus: and this being found agreeable to the observed motion of comets, has been since allowed by astronomers to be their real motion. It seems however not agreeable to the uniformity of the universe, that after a short view of the sun, they should be continually flying farther off, in that wide void beyond the planetary bounds, to creep along that dark cold region for millions of years; (and in less time than that, they could not reach any other system, if the parallax of the fixed stars be two seconds, which Dr. Bradley has found it cannot exceed;) but that they should rather revolve round the sun, in certain, though long periods; and the likeness of the elements of some of the comets seen in different ages, make it probable they were the same returning again; if so, their trajectories are not really parabolas; but they seem a kind of planets, revolving round the sun in so extremely excentric ellipses, that, so far as we can see them, they are not sensibly different from parabolas, which for ease of calculation we always suppose them to be: and that their motion is almost exactly a parabola, is easy to be demonstrated. The true motion of comets being thus known, Sir Isaac Newton applied himself to find a method, by which a comet's orbit might be determined from a course of observations; and, having attempted many ways in vain, hit at last on one, which he has explained, Book III. Prop. 41, &c. of his Principia, taking for his example the comet of 1680. The same method Dr. Halley used for twenty-three more, some accurately, others grossly, as the observations he met with were; and several more have been done since by others. From the likeness of the elements, some of these are supposed to be different returns of the same comet: first, those of 1531, 1607, and 1682, with a period of 75 or 76 years, may be expected again about 1758: secondly, those of 1532 and 1661, after a period of 128½ years, may probably return about 1789: thirdly, the observations of that in 1556 were very gross, and those in 1264 still more defective, so that neither orbit can be supposed to be at all accurate; yet from their likeness, though not agreeing very well, may not unlikely be the same, and come again, after a period of 292 years, about 1848: lastly, the comet of 1680 was a very remarkable one; and as at equal intervals, A. C. 44, A. D. 531, and 1106, others were seen in some respects like it, several persons have supposed they might be the same, being 575 years going round the sun; yet no observations being made at any of the three former times, it was but a guess; and if the comet of 1106 was seen in March in Cancer, as the manuscript Mr. Dunthorne mentions, Phil.

Transf. XLVII. p. 287, seems to say, it could by no means be the same as that of 1680, which cannot get beyond Taurus in March, nor be seen in Cancer after December; the period therefore of that comet must remain doubtful, till further light appears.

It may be objected, that the two periods of the comet of 1682 being a whole year different one from the other, there is no knowing when to expect it again. The difference indeed is very great, considering how true the planet's motions are found to be; yet I fear we must not expect the same regularity in a comet's orbit as in a planet's, they being subject to many great errors: first, crossing all or most of the planet's paths, they may come nearer to one or other of them than any of the planets do to each other, and be more affected by their mutual attraction; especially if near Jupiter or Saturn, the greatness of which bodies, weaker power of the sun, slowness of their motion, and consequent long continuance near one another, and direction of the comet's path nearly toward the sun, all join to make the alteration of its orbit more sensible: 2dly, a small change of angle will make little difference in a planet's orbit, which is always nearly perpendicular to the sun; but when a comet's path makes only five or ten degrees angle with a line from the sun, a little variation will bear a greater proportion to that small angle, than to 90 degrees: 3dly, as a comet's greatest distance is many times its least, if by a planet's attraction the perihelion is altered but a few miles, that may be greatly multiplied in the aphelion; and if the angle at first is changed but one minute, it may make a great alteration of length, in running four times as far as Saturn, and back again: 4thly, there is but little difference in the velocity of a body, going round the sun in one or two hundred years, and of one keeping a perfect parabola; small therefore must be the difference of one revolving in 75 or 76 years, especially if the same power, which increases its velocity, should make its perihelion distance greater. Now the comet of 1682, in its descent toward the sun, may be near Mars, but that being small will hardly affect it much; again, in going from the sun, it may pass near Venus, a little before it gets to the descending node, and near the earth a little after it: if then one or more of these planets should be in that part of their orbit when the comet passes by, they may make some change in its motion. The comet of 1680 is very liable to alteration, as in its descent it may pass not remote from any of the planets, extremely near the earth, and but a little way from Venus; its motion also being all the time almost directly toward the sun, and its perihelion distance so very small, a little change in its motion might make a very great one in its orbit.

The method Sir Isaac Newton gives, in his Principia, is from three observations of a comet, at proper intervals, to find its real trajectory; and

Book III. Prop. 41, he has explained in order the several processes, designed chiefly for construction, which was the way he used in his example of the comet of 1680. This operose problem Dr. David Gregory has more fully explained and demonstrated, in the fifth book of his astronomy: it may also be reduced to triangles, and calculated by numbers, which is much more accurate than construction by lines; and though consisting of about an hundred triangles, Dr. Halley undertook it for 24 comets, as others have since for 20 more; and some of them, by greater care or nicer observations to a very great degree of exactness. Yet as a compleat list of the triangles used, and several cautions necessary in practice, are not published, I have chosen to set them down here, not generally repeating the demonstrations, which Sir Isaac Newton and Dr. Gregory have already done, but supposing one of those books at hand, to add some observations for preventing mistakes, and shewing how it may be reduced to triangles: the letters here used are the same as in Sir Isaac Newton, except some few which he had not, and are generally those which Dr. Gregory uses.

He then who would calculate a comet's orbit by triangles, should first construct it as true as may be by lines; for as the method is approximation, it is to no purpose to calculate nicely, while the point tried is much wrong, as the first guess will most likely be; and as the accuracy depends on having, in fig. 2.) B near μ , (see Greg. V. 18, 19.) he cannot at first chuse such observations as will make it so. First therefore, out of a set of observations on a comet, chuse three so that you gets that interval of time when the comet was nearest the sun is the shortest, but no great nicety is required this first time. On a large sheet of pasteboard, draw a circle ten inches radius for the *magnus orbis*; mark the points the earth was in at the three times of observation, and call them T, t , and τ , (see fig. 1); from these draw the three observed longitudes of the comet, TA, t B, and τ C: on t B take any point B, let V be the intersection of St and T τ , and γ the place the comet was in perpendicularly over B; make $S\gamma^2 : SB \times R^2 :: tV : BE$, which fell off on the line SB: through E (Newton's Princip. III. lemma 7.) draw AC cutting TA and τ C, so that AE : EC as the time between the first and second observations, to the time between the second and third. A and C are near enough for the first trial, the curvate places of the comet in its orbit. To try how true they are, let TA be to the perpendicular AM, as radius to the tangent of the comet's apparent latitude the first time, and τ C : CN :: R : tang. of apparent latitude the last time, and draw MN the chord of the parabolick arc M γ N, along which the comet moved, while the projection of the points on the ecliptick are A, B, C: then say $SB : S\gamma :: SB + \frac{2}{3} BE$ to a fourth number nearly equal

equal to (SR, see Greg. V. 20.) the distance from the sun at which a comet would move the chord MN, in the same time as it really did go the arc M γ N: let X be the length run by a comet at the earth's mean distance from the sun, in the time between the first and third observations (Newton's Prin. III. 40.) then $\sqrt{SR} : \sqrt{\text{radius}} :: X : MP$, being the length a comet would go in the same time at the height SR. If MN be equal to MP, the point B was taken right; but if very different, as may easily be this first time, take a new point *b*, find *ac*, and try till MN is nearly equal to MP. Being now near the matter, we must be more exact: bisect the truest AC in I, (see fig. 2.) erect a perpendicular $Ii = Bb$, draw Si , and erect $\lambda\mu$: if μ falls on or near B, the observations are rightly chosen; if not, take one or more new observations, to make B as near as possible to μ , and rather between i and μ than otherwise, (Greg. V. 18, 19.)

The circle drawn for the *magnus orbis* will do again, as will T, t and τ , if carefully drawn as to angle and distance, and the same observations are still used; as also the three longitudes T A, t B, and τ C. Set off t B as near as now known, draw AC as before, bisect in I, erect the perpendicular $Ii = Bb$, (see fig. 2.) complete the rectangle $Ii\lambda\mu$, and μ is nearly the vertex of the parabolic arc ABC; (Greg. V. 19. coroll.) but may be further corrected thus. Produce $I\mu$ to n , so that $\mu n = \frac{1}{2} I\mu$; through S draw $n\xi = 3 S n$, in the line B ξ take a new point E', and if the former length BE is not true enough, which yet it will generally be for construction, a truer length for BE' may be found as directed presently for calculation, thus: a sidereal year is to the time between the first and third observations,* as the circumference of a circle to the length of the mean arc the earth moves in that time; the square of half that arc divided by twice the radius, is the fall of the earth in half the time: this, if now done accurately, need not be repeated in N $^{\circ}$. 7 of the calculation: then SB : S γ :: SB + $\frac{1}{2} I\mu$: SL and SL γ : R α $\times$ SB + $\frac{1}{2} I\mu$:: the fall of the earth : BE the fall of the comet. Through E' draw A' C', and form the rectangle $I'i'\lambda'\mu'$, μ' is the vertex of the parabolic arc, (Greg. V. 19. coroll.) and B ξ divides the chord very nearly in proportion to the times (V. 18.) It remains then to try whether the point B was guessed right: say then SB : S γ :: S μ + $\frac{1}{2} I'\mu'$: SR, and as above find MN and MP: if they are not equal, draw GP parallel to C'N, then is C'G the error; take a new length $t b$, and repeat the process to find a new $m n$ and $m p$, and error $c'g$. The two figures 3, which are the small part YCG of fig. 1. and 2, shew the two cases of this correction, when C and c are on the same or opposite sides of z ; where a line drawn through G and g the two points of error will cut YC, that is in the point the comet was really over, when, by a wrong guess at the length $t B$ and $t b$,

it came out C and c ; and setting off A'F and $a'f$ equal to C'G and $c'g$, the true point x may be in like manner found. We may now either proceed to calculate the orbit arithmetically, from the length of $t B$ now very nearly known, or find the elements of the orbit by construction thus; (see fig. 4.) two points of a parabola m and n , perpendicularly over the curtate places x and z , with the focus the sun, determine the whole curve: draw then xz , and erect two perpendiculars xm and zn , the tangents of the comet's latitude at the first and third observations, T x and τz being the radii; S Q drawn through the sun and the intersection of xz and mn , is the position of the comet's node. $z\rho$ a perpendicular let fall from z on S Q, is to zn the tangent of its latitude, as radius, to tangent of the inclination of the orbit. Produce the perpendiculars $x\sigma$ and $z\rho$ to m and n , as cosine of inclination to radius, which will be in that position to each other, the sun and line of nodes, as the comet was in its orbit at the first and third observations; on m and n (fig. 5) with radius S m and S n draw two circles; a tangent to both circles may be drawn by the eye, or thus, bisect mn , draw a circle on that center passing through m and n , and set of $m_1 = n\gamma = S n - S m$, which produce to δ and κ ; $\pi\kappa\delta$ being parallel to $m\gamma$, which is perpendicular to both radii $m\kappa$ and $n\delta$, touches both circles, and S π a perpendicular on it from S, is double the perihelion distance: (De la Hire's plain conicks.) Wherefore P, the bisection of S π , is the vertex of the parabola or perihelion point, whose position is determined by the angle nSP or mSP ; as is the time the comet was there, because the parabolick space nSm , is to the parabolick space mSP , as the time between the observations, to the time between the perihelion and first observation.

Thus are the elements of a comet's orbit found by construction; but if exactness is required, lines will not do it, but the process must be reduced to triangles, and calculated by numbers. And first see that the observations are good, or else be content with construction, for it is to little purpose to calculate nicely by uncertain data. Next try whether the times are rightly chosen, by the directions already given, (see page 7.) and, for further accuracy, be not content with the earth's places as found by the tables of the sun, but correct them by the mensural parallax. The weight of the earth being to that of the moon as 39.788 to 1, the distance of the moon, is to the distance of the common center of gravity, as 40.788 to 1. (Newton Prin. III. 37. cor. 4 and 6.) In fig. 6. E is the earth, and M the moon, revolving round C their common center of gravity which moves regularly along the *magnus orbis* ACB round the sun S; then at any time the line of the moon's horizontal parallax, is to the sine of the sun's parallax divided by 40.788, as SC to CE. In the triangle SCE, given SC, CE and SCE, then CSE is the required correction of the sun's place, and

and SE the real distance of the earth from the sun. This triangle however need not be solved, the tables IV. and V. giving the required correction in angle, and the length of the line ED, to be added to or subtracted from SC, the distance of the sun as found by the common tables. As the moon has sometimes above five degrees of latitude, and therefore the earth is not absolutely in the plain of the ecliptic, for perfect exactness that should be allowed for; but as the whole menſtrual parallax is very ſmall, this, which is but a ſmall part of it, may I ſuppoſe be ſafely

neglected. Laſtly, before calculating, draw a ſet of figures ſuited to the particular caſe, for no general rule can be given where to add and where ſubſtract; the caſe I have drawn, and ſuited the plus and minus to, is the comet of 1742; and another ſet of figures will ſhew, whether to add or ſubſtract in that caſe. Thus prepared, the following is a liſt of the triangles required, what is given and what is ſought, for fixing the due length of the lines, which determine the comet's trajectory.

102		Parabolic space $PS n - P S m$, is to $P S m$, as time between the observations } Time of to the time between the perihelion and first observation. } Perihelion		

N. B. The parabolic space may be either taken out of the table of the parabola, or calculated in the same manner that was done.

N^o. 7. I call the time between the first and second observations U , and that between the second and third W . Then a sidereal year is to the whole time, as the circumference of the circle to the arc moved in that time: and the square of half that arc, divided by twice the radius, is the earth's fall toward the sun in half the time.

N^o. 6, 7, 8. I find BE this way rather than Sir Isaac Newton's, which is only an approximation, and irregularly too great or too small, as the times are more or less unequally divided, and $T\tau$ in the more or less curved parts of the earth's orbit. But this way, if found as in N^o. 23, 24. would be true; and $S\mu$ being not yet known, I use SB for it, which is nearly the same: nor is $I\mu$ yet found, but as the comet has been already constructed, it is there given near enough for this process.

N^o. 20. Since, by Greg. V. 18, the right line $nS\xi = 3 S n$ is the truth, full as easy, and, requiring no taking out natural numbers, is less liable to error, I wonder Sir Isaac chose to approximate it by the point σ , and $\sigma\xi = 3 S\sigma + 3 i\lambda$. (See his fig. Book III. Prop. 41.)

N^o. 23, 24. In Greg. V. 21, the comet's fall at the height SL is $MV = VZ$, (see his fig.) Now B and μ nearly coinciding, by similar triangles $SB : S\gamma (N^o. 5) :: SL (= S\mu + \frac{1}{2} I\mu) : SL$. Again, $SL^2 : R^2 :: \epsilon\downarrow$ (the earth's mean fall): the fall at the point L . Greg. I. 42. And by similar triangles $SL : S\mu + \frac{1}{2} I\mu :: \epsilon\downarrow$ the fall at $L : BE$; then $SL^2 : R^2 \times S\mu + \frac{1}{2} I\mu :: \epsilon\downarrow : BE$. This is the true length of μZ or BE ; and seldom sensibly different from BE , which yet being more perpendicular to AC , is a little shorter; and if BE is so long and so oblique to AC , that the very small angle EBE' will sensibly alter its length, then the fine of $BE' b$: fine of $BE b :: BE : BE'$ may be something truer.

N^o. 36. The third proportional to $S\mu + \frac{1}{2} I\mu$, which is the truth, see Greg. V. 20, is easier found in Logarithms than $S\mu + \frac{3}{2} I\mu$.

N^o. 37. It is here fit to shew cause for this considerable variation from Sir Isaac Newton. Greg. V. 20, shews that a body at the height SR (see his fig.) would move the chord AB , while the comet really moved the arc AVB . Now μ , l and r , in

fig. 2, are the projection on the plain of the ecliptic of his V, L and R : then SR, the hypothenuse of the right-angled triangle S ρ R, is Gregory's line SR, and therefore the length sought. Sir Isaac's ID = $S\mu + \frac{2}{3}i\lambda$ is nearly the same as S ρ ; but his IO, being the comet's mean height above the ecliptic, may if the time is unequally divided, and the inclination of the comet great, considerably differ from the height sought at S ρ , which is in S μ produced : therefore, as in N o . 23, SB : Sy :: S ρ : SR, by similar triangles.

N o . 38, 39. M and N being the points the comet was really in, perpendicular over A' and C', T A' curtate distance, is to A' M the height, as radius to tang. of the apparent latitude at the first observation. The like of C' N.

N o . 41. The reason of this double proportion is this : MN, and of course A' C' and the perpendicular Y e , is too large in the proportion of MN to MP; but MP will increase or diminish, as $\sqrt{S\gamma}$ is less or greater than $\sqrt{S\gamma}$. Greg. I. 27. This however is very hard to find, and only an approximation at last. An easier and as good a way is, to compare the error of the last construction with the error now found by calculation : thus NP — NP the difference of the errors, is to t B — t B the difference of the guesses, as NP the present error, to the required correction of t B.

N o . 80, 81. Sir Isaac Newton takes CG = NP; but as the correction is in the plain of AC, not of MN, I make G the projection of P, as C is of N. And if CG is not parallel to cg (fig. 3.) or Cc bears not the same proportion to τC , as Aa to TA, it may make some difference in the places of x and z , though seldom much.

N o . 80, 81, 82, 84, are not wanted if AC is parallel to ac ; for then 83 and 85 will be, NP + np : NP :: Aa : Ax :: Cc : Cz.

Sir Isaac Newton in his next proposition, and Dr. Gregory V. 31, shew how, by the rule of false, to correct still further the comet's orbit as above found : but that I have here omitted, as hoping and expecting that the directions I have given, being contrived to avoid all error as much as possible, will give the orbit true enough without that laborious correction, which I can hardly think is much less trouble than the calculation of the orbit itself. The changing the comet's parabolick orbit into its real elliptical one, by this correction, thereby to discover its period, can doubt be at best but imperfectly done, from the small part of the orbit we can see, especially if so true a parabola as the comet of 1744 had : and unless we see a comet for a very long time, we must be content to wait for that more certain, though tedious discovery, the returning after another period. If any one however, desirous of the utmost exactness, chuses to undertake this last correction, Sir Isaac Newton and Dr. Gregory have both explained and shewn the

use of it. (See Plate facing the article COMET.)
Barker on Comets.

COMETARIUM, a curious machine to shew the revolution of a comet about the sun.

Dr. Defagulier was the first who described it under the character of a planetarium; and by it represented the motion of the planet Mercury : but since him, it has been described under the character of a cometarium by Mr. Ferguson, Mr. Martin, and several others in their mechanical lectures, being much more adapted to represent the motion of a comet, than a planet; because none of the planets describe orbits sensibly elliptical; whereas those of the comets are very much so.

We shall here give the representation of a cometarium (as in Plate XXXVI. fig. 1.) adapted to the motion or theory of the comet of the year 1682, whose period is 75 $\frac{1}{2}$ years.

The construction of the parts of this machine with the rationale is as follows, taken from p. 142. of Mr. Martin's lectures. When the lid is taken off the box, the internal parts appear as in Plate XXXVI. fig. 2. NO and QT are two elliptic wheels turning each other about the foci I and S, by means of a cat-gut string in a groove on their edges, crossing at K. These oval wheels are fixed on arbors or axes, which pass through the same focus S and I in each; the oval NO is moved by the circular wheel I, fixed also upon the same axes, but above it upon the bar or long piece GV; which wheel is itself moved by another equal wheel G, and that by an endless screw turned by a winch on the outside of the box, all which is evident in the figure.

The perimeter of the oval QT, where it touches that of NO, will have a velocity always proportional to the distance from I; that is, in the points K, 4, 3, 2, 1, &c. The velocities will be as the lines IK, 14, 13, 12, 11, &c. which we consider as levers acting upon and moving the oval QT in those points. Now if the ovals are such that IK, is to SV, or IK, to I τ , as 6 to 1, then will the point K have six times the velocity turned by the lever IK, as the point V will have when it has made $\frac{1}{6}$ a revolution, or is come under the point S, where it is turned by the lever I τ , than in the situation IS.

If we take SP = SK = I τ , and upon the point S, S, τ , as foci, describe the ellipsis PLIM, that will represent the orbit of the comet, or the figure of the groove on the lid of the box, in which a round brass ball, representing the comet, is made to slide along on a piece of wire, called the radius vector, fixed at one end into the top of the arbor at S, where we suppose the sun to be, and is accordingly represented by a silver plate at top.

The place of the comet at P is called the perihelion, as being there nearest the sun; as I is its aphelion or point of greatest distance. Since

SP = SK, the velocity of the comet will be in the point P equal to that of the point K; and were the comet's aphelion at *s*, its velocity then would be equal to that of the point V, when under *s*, viz. six times less than before; but since the comet's aphelion is at I, and since the greater arch described in the same time must have a greater velocity, the velocity of the comet at I will be about $\frac{1}{2}$ of that at P.

If the ellipsis on the lid of the box be divided into 100 parts, to shew the anomaly of the comet, and about the axis of the wheel G be placed a circle EF, divided into equal parts, representing the years or period of the comet, with a proper index pointing to these divisions, the instrument will shew the several particulars relating to the theory of elliptic motions, whether of a planet or comet.

COME-UP, in the marine, the order to slacken or cast-off any rope which had been drawn tight on some particular occasion; as, come-up the capstern, *i. e.* slacken the rope on the capstern; come-up the cat, *i. e.* slacken the cat-fall. See the article CAPSTERN and CAT.

COMFRY, *Symphytum*, in botany. See the article SYMPHYTUM.

COMING-TO, or COMING-TO an Anchor, in the marine, the same with letting the anchor go, to fasten the ship in a road, bay, or harbour.

COMITIA, in Roman antiquity, an assembly of the people, either in the comitum or campus-martius, for the election of magistrates, or consulting on the important affairs of the republic.

COMITUM, in Roman antiquity, a large hall in the forum, where the comitia were ordinarily held.

COMMA, among grammarians, a point or character marked thus (,) serving to denote a short stop, and to divide the members of a period.

COMMA, in music, an interval equal to the difference of the tone major and minor, and expressed by the ratio 81 : 80. See the articles INTERVAL and TONE.

COMMAND, in the royal navy, implies the rank and power of an officer who has the management of a ship of war under twenty guns, called a sloop, also that of an armed ship or bomb-vessel, whence

COMMANDER is an officer who governs a sloop of war, armed-ship, or bomb-ketch, and who has the rank of a major in the army.

COMMANDING GROUND, in the military art, an eminence overlooking any post or strong place.

A commanding ground is of three kinds: first, a front ground, being an height, opposite to the face of some post, which plays upon its front. Secondly, a reverse ground, being an eminence that can play upon the back of any post. Thirdly, an enfilade commanding ground, being an eminence that, with

its shot, can scour all the length of a straight line.

COMMANDMENT, in a legal sense, is used variously: sometimes it is taken for the commandment of the king; as when, upon his own motion, and from his own mouth, he orders any person to prison. Sometimes it is used for the commandment of the justices: this commandment is either absolute, or ordinary: absolute is when a justice commits a person to prison for contempt, &c. upon his own authority, as a punishment: ordinary is where a justice commits a person rather for safe custody than for punishment; the person thus committed by ordinary commandment is bailable. In another sense of the word, magistrates may command others to assist them in the execution of their offices, in order to keep the king's peace, &c.

COMMANDMENT is likewise used for the offence of a person that wills or orders another to do some unlawful act, as theft, murder, or the like. To command any one to commit burglary, is felony excluded clergy; and he who commands the doing any act that is unlawful, is accessory to it and all the consequences thereof, if executed in the same manner as commanded; though not where it varies, or where the commander revokes the command. In trespasses, &c. a master shall be charged with the acts of his servant done by his command: however, servants shall not be excused for committing any crime when they act by command of their masters, who have no such power over them as to enforce such commandments. The commands of infants or femme-coverts are void.

COMMANDRY, a sort of benefice, or certain revenue, belonging to a military order, and conferred on ancient knights, who had done services to the order, as the commandries of Malta.

COMMELINA, in botany, a genus of plants whose corolla consists of six petals, the exterior three of which are small, oval, and concave, of the dimensions of the perianthium: the three interior and alternate petals are large, roundish, and coloured; containing three subulated reclining filaments, terminated with ovated anthers.

The fruit is a naked roundish capsule, with three cells, and divided by three valves, and contains two-angled seeds.

COMMENDAM, in the ecclesiastical law, the trust or administration of the revenues of a benefice, given either to a layman, to hold, by way of depositum, for six months, in order to repair, &c. or to an ecclesiastic, or beneficed person, to perform the pastoral duties thereof, till once the benefice is provided with a regular incumbent.

COMMENSURABLE QUANTITIES, in geometry, are such as have some common aliquot part, or which may be measured by some common measure, so as to leave no remainder in either. Thus a foot and a yard are commensurable, there being a

third quantity which will measure each, as an inch taken twelve times makes a foot, and thirty-six times a yard.

COMMENSURABLES are to each other either as units to a rational whole number, or as one rational whole number to another.

COMMENSURABLE NUMBERS, whether integers or fractions, are such as have some other number which will measure or divide them without any remainder; thus, 6 and 1, $\frac{8}{12}$, and $\frac{1}{2}$, are respectively commensurable numbers.

COMMENSURABLE in Power, is when the squares of right lines are measured by one and the same space, or superficies.

COMMENSURABLE SURDS, are such surds, as being reduced to their least terms, become true figurative quantities of their kind, and are therefore as a rational quantity to a rational.

COMMENTARY, or **COMMENT**, in matters of literature, an illustration of the difficult or obscure passages of an author.

COMMENTARY, or **COMMENTARIES**, likewise denotes a kind of history or memoirs of certain transactions, wherein the author had a considerable hand: such are the *Commentaries of Cæsar*.

COMMERCE, a term used for the buying, selling, or bartering of all manner of commodities, in order to profit by the same.

COMMINUTION denotes the breaking, or rather grinding, a body into very small particles.

COMMISSARY, in the ecclesiastical law, an officer of the bishop, who exercises spiritual jurisdiction in places of a diocese so far from the episcopal see, that the chancellor cannot call the people to the bishop's principal consistory court, without giving them too much inconveniency.

COMMISSARY, in a military sense, is of three sorts.

COMMISSARY General of the Musters, an officer appointed to muster the army as often as the general thinks proper, in order to know the strength of each regiment and company, to receive and inspect the muster-rolls, and to keep an exact state of the strength of the army.

COMMISSARY General of Stores, an officer in the artillery, who has the charge of all the stores, for which he is accountable to the office of ordnance.

COMMISSARY General of Provisions, an officer who has the inspection of the bread and provisions of the army.

COMMISSARY of a Ship of War, the same with purser. See the article **PURSER**.

COMMISSION, in common law, the warrant or letters patent which all persons, exercising jurisdiction, have to empower them to hear or determine any cause or suit; as the commission of the judges, &c.

COMMISSIONER, a person authorized by commission, letters patent, or other lawful warrant, to examine any matters, or execute any public office, &c.

COMMISSIONERS of the Navy, certain officers appointed to superintend the marine under the direction of the lord high-admiral, or lords commissioners of the admiralty.

The duty of these officers does not extend to the internal government of ships in commission either at sea or in port, as they are invested with no military command, but is more immediately concerned in the building, docking, repairing, cleaning, &c. of ships in the dock-yards. They have also the appointment of some of the warrant-officers, as masters and surgeons of ships.

The principal officers and commissioners residing at the board are, 1. The comptroller. 2. Two surveyors, who are shipwrights. 3. Clerk of the acts. 4. Comptroller of the treasurer's accounts. 5. Comptroller of victualling accounts. 6. Comptroller of the store-keepers accounts. 8. An extra-commissioner.

Besides these there are three resident-commissioners who manage the affairs of the dock-yards of Chatham, Portsmouth, and Plymouth; for an account of whose duty see the article **DOCK-YARD**.

COMMISSIONERS for victualling the Navy, certain officers appointed to contract for, and furnish the king's ships, or fleets with provisions of all species. See the article **VICTUALLING-OFFICE**.

COMMISSURE, in architecture, &c. the joint of two stones, or the application of the side of one to that of the other.

COMMITMENT, in law, the sending of a person, charged with some crime, to prison, by warrant, or order.

COMMITTEE, one or more persons to whom the consideration or ordering of a matter is referred, either by some court, or by the consent of parties, to whom it belongs.

COMMITTEE of Parliament, a certain number of members appointed by the house for the examination of a bill, making report of an inquiry, process of the house, &c.

COMMODITY, in a general sense, denotes all sorts of wares and merchandises whatsoever, that a person deals or trades in.

Staple COMMODITIES, such wares and merchandises as are commonly and readily sold in a market, or exported abroad; being, for the most part, the proper produce or manufacture of the country.

COMMODORE, a general officer of the marine, invested with the command of a detachment of ships of war on any particular enterprise, during which time he bears the rank of brigadier general in the army, and is distinguished from the inferior ships

of his Squadron, by a broad red pendant tapering to the outer end, and forked.

COMMODORE is also a name given to some select ship in a fleet of merchantmen, who leads the van in time of war, and carries a light aloft to conduct and keep together the rest.

COMMON, something that belongs to all alike, in contradistinction to proper, peculiar, &c. Thus the earth is said to be our common mother.

COMMON DIVISOR, is a quantity or number which exactly divides two or more quantities without leaving any remainder.

COMMON, in geometry, is applied to an angle line, or the like, which belongs equally to two figures.

COMMON LAW, that body of rules received as law in England, before any statute was enacted in parliament to alter the same.

COMMON-PLACE BOOK, *Adversaria*, among the learned, denotes a register of what things occur worthy to be noted in the course of a man's study, so disposed, as that among a number of subjects, any one may be easily found.

COMMON-PLEAS is one of the king's courts now held constantly in Westminster-hall, but anciently was moveable.

COMMON, in law, that soil, the use of which is common to this or that town or lordship.

COMMON PRAYER is the liturgy in the church of England.

COMMON, in grammar, denotes the gender of nouns which are equally applicable to both sexes: thus *parens*, a parent, is of the common gender.

COMMON, in geometry, is applied to an angle, line, or the like, which belongs equally to two figures.

COMMONS, or *House of COMMONS*, a denomination given to the lower house of parliament. See **PARLIAMENT**.

COMMONS, or **COMMONALTY**, likewise signifies the whole body of the people under the degree of a baron, whether knights, gentlemen, burgesses, yeomen, &c.

COMMONWEALTH, the same with republic. See the article **REPUBLIC**.

COMMOTION, an intestine motion in the parts of any thing.

COMMUNICATION, in a general sense, the act of imparting something to another.

COMMUNICATION is also used for the connection of one thing with another, or the passage from one place to another: thus a gallery is a communication between two apartments.

COMMUNICATION of Idioms, in theology, the act of imparting the attributes of one of the natures in Jesus to the other.

COMMUNICATION of Motion, in philosophy, is the action of a moving body, whereby a body at

rest is put in motion, or a body already in motion is accelerated.

Before we proceed to explain the laws, by which bodies communicate their motion from one to another, it is very necessary to make a distinction between motion and velocity; which ought to be well observed, and is as follows.

By the motion of a body (sometimes called its quantity of motion, sometimes its momentum) is not to be understood the velocity only, with which the body moves; but the sum of the motion of all its parts taken together: consequently the more matter any body contains, the greater will be its motion, though its velocity remains the same. Thus, supposing two bodies, one containing ten times the quantity of matter the other does, moving with equal velocity; the greater body is said to have ten times the motion, or momentum, that the other has: for it is evident, that a tenth part of the larger has as much, as the other whole body. In short, that quality in moving bodies, which philosophers understand by the term momentum or motion, is no other than what is vulgarly called their force, which every one knows to depend on their quantity of matter, as well as their velocity. This is that power, a moving body has to affect another in all actions that arise from its motion, and is therefore a fundamental principle in mechanics.

Now, since this momentum, or force, depends equally on the quantity of matter a body contains, and on the velocity with which it moves; the method to determine how great it is, is to multiply one by the other. Thus, suppose two bodies, the first having twice the quantity of matter, and thrice the velocity which the other has; any two numbers, that are to each other as two to one, will express their quantities of matter (it being only their relative velocities and quantities of matter which we need consider) and any two numbers that are as three to one their velocities; now multiplying the quantity of matter in the first, viz. two by its velocity three, the product is six; and multiplying the quantity of matter in the second by its velocity, viz. one by one, the product is one; their relative forces therefore or powers will be as six to one, or the moment of one is six times greater than that of the other. Again, if their quantities of matter had been as three to eight, and their velocities as two to three, then would their moments have been as six to twenty-four, that is, as one to four.

This being rightly apprehended, what follows, concerning the laws of the communication of motion by impulse, and the mechanical powers, will be easily understood.

I. In bodies not elastic.

Those bodies are said to be not elastic, which, when

when they strike against one another, do not rebound, but accompany one another after impact, as if they were joined. This proceeds from their retaining the impression, made upon their surfaces, after the impressing force ceases to act. For all rebounding is occasioned by a certain spring in the surfaces of bodies, whereby those parts, which receive the impression made by the stroke, immediately spring back, and throw off the impinging body; now, this being wanting in bodies void of elasticity, there follows no separation after impact.

When one body impinges on another which is at rest, or moving with less velocity the same way, the quantity of the motion or momentum in both bodies taken together, remains the same after impact as before; for by the third law of nature, the reaction of one being equal to the action of the other, what one gains the other must lose.

Thus, suppose two equal bodies, one impinging with twelve degrees of velocity on the other at rest; the quantities of matter in the bodies being equal, their moments and velocities are the same; the sum in both twelve; this remains the same after impact, and is equally divided between them; they have therefore fix a-piece, that is, the impinging body communicates half its velocity, and keeps half.

When two bodies impinge on each other by moving contrary-ways, the quantity of motion they retain after impact, is equal to the difference of the motion they had before; for by the third law of nature, that which had the least motion, will destroy an equal quantity in the other, after which they will move together with the remainder, that is the difference.

Thus for instance, let there be two equal bodies moving towards each other, the one with three degrees of velocity, the other with five, the difference of their moments or velocities will be two; this remains the same after impact, and is equally divided between them, they have therefore one a-piece; that is, the body, which had five degrees of velocity, loses three, or as much as the other had, communicates half the remainder, and keeps the other half.

From these positions it is easy to reduce a theorem, that shall shew the velocity of bodies after impact in all cases whatever. Let there be two bodies A and B, the velocity of the first a , of the other b ; then the moment of A will be expressed by Aa , and of B by Bb ; therefore the sum of both will be $Aa + Bb$, and $Aa - Bb$ will be the difference when they meet. Now these quantities remain the same after impact; but knowing the quantities of motion and quantities of matter, we have the velocity (by dividing the former by the latter: therefore $\frac{Ab + Bb}{A + B}$ or $\frac{Aa - Bb}{A + B}$ will in all cases express the velocity of the bodies after impact.

II. In elastic bodies.

Bodies perfectly elastic, are such as rebound after impact, with a force equal to that with which they impinge upon one another: those parts of their surfaces that receive the impression, immediately springing back, and throwing off the impinging bodies with a force equal to that of impact.

From hence follows, that the action of elastic bodies on each other (that of the spring being equal to that of the stroke) is twice as much as the same in bodies void of elasticity. Therefore, when elastic bodies impinge on each other, the one loses and the other gains twice as much motion as if they had not been elastic; we have therefore an easy way of determining the change of motion in elastic bodies, knowing first what it would have been in the same circumstances had the bodies been void of elasticity.

Thus, if there be two equal and elastic bodies, the one in motion with twelve degrees of velocity impinging on the other at rest, the impinging body will communicate twice as much velocity as if it had not been elastic, that is, twelve degrees, or all it had; consequently it will be at rest, and the other will move on with the whole velocity of the former.

It sometimes happens, that in bodies not elastic, the one loses more than half its velocity, in which case, supposing them elastic, it loses more than all; that is, the excess of what it loses, above what it has, is negative, or in a contrary direction: thus, suppose the circumstances of impact such, that a body which has but twelve degrees of velocity loses sixteen; the overplus four is to be taken the contrary way; that is, the body will rebound with four degrees of velocity, *v. g.* Let it be required to determine the velocity of a body, after impact, against an immoveable object. Let us first suppose the object and body both void of elasticity, it is evident the impinging body would be stopped or lose all its motion and communicate none; if they are elastic, it must lose twice as much, and consequently will rebound with a force equal to that of the stroke.

It is sufficient if only one of the bodies is elastic, provided the other be infinitely hard; for then the impression in the elastic body will be double of what it would have been, had they both been equally elastic; and consequently the force with which they rebound, will be the same as if the impression had been equally divided between the two bodies.

There are no bodies that we know of, either perfectly elastic, or infinitely hard; the nearer therefore any bodies approach to perfection of elasticity, so much the nearer do the laws, which they observe in the mutual communication of their motion, approach to those we have laid down.

Sir Isaac Newton made trials with several bodies, and found that the same degree of elasticity always appeared

appeared in the same bodies with whatever force they were struck, so that the elastic power in all the bodies he made trial upon, exerted itself in one constant proportion to the compressing force. He found the celerity with which balls of wool, bound up very compact, receded from each other, to bear nearly the proportion of five to nine to the celerity wherewith they met; and in steel he found nearly the same proportion; in cork the elasticity was something less, but in glass much greater; for the celerity, with which balls of that material separated after percussion, he found to bear the proportion of fifteen to sixteen to the celerity wherewith they met.

We have hitherto supposed the direction in which bodies impinge upon one another, to be perpendicular to their surfaces: when it is not so, the force of impact will be less, by how much the more that direction varies from the perpendicular; for it is manifest that a direct impulse is the greatest of all others that can be given with the same degree of velocity.

The force of oblique percussion is to that of direct, as the sine of the angle of incidence to the radius.

Let there be a plane as AD (Plate XXXVI. fig. 3.) against which let a body impinge in the point D in the direction BD; which line may be supposed to express the force of direct impulse, and may be resolved into two others, EC and BA; the one parallel, the other perpendicular to the plane; but that force which is exerted in a direction parallel to the plane can no way affect it, the stroke therefore arises wholly from the other force expressed by the line BA, but this is to the line BD, as the sine of the angle of incidence ADB to the radius; from whence the proposition is clear.

If the surface of the body to be struck is a curve, then let AD be made a tangent to D, the point of incidence, and the demonstration will be the same.

This is the case, when bodies impel one another by acting upon their surfaces; but in forces, where the surfaces of bodies are not concerned, as in attraction, &c. we must not consider the relation which the direction of the force has to the surface of the body to be moved, but to the direction in which it is to be moved by that force. Here the force of action will be less, by how much the more these two directions vary from each other.

The force of oblique action is to that of direct, as the co-sine of the angle comprehended between the direction of the force, and that wherein a body is to be moved thereby to the radius.

Let FD (fig. 4.) represent a force acting upon a body as D, and impelling it towards E; but let DM be the only way in which it is possible for the body to move; the force FD may be resolved into two others, FG and FH, or which is equal to it GD; but it is evident that only the force GD impels it towards M. Now, FD being the radius,

GD is the co-sine of the angle FDG, comprehended between the two directions FE and GM; from whence the proposition is clear.

My meaning in both cases will be understood from the instance of a ship under sail. The force by which the wind acts upon the sail, will be less, by how much the more its direction varies from one that is perpendicular to its surface: but the force of the sail to move the ship forward, will be less, by how much the more the direction of the ship's course varies from that in which she is impelled by the sail.

To this we may add the following proposition relating to oblique forces, viz. that, if a body is drawn or impelled three different ways at the same time, by as many forces acting in different directions; and if the quantity of those forces is such, that the body is kept in its place by them, then will the forces be to each other, as the several sides of a triangle, drawn respectively parallel to the directions in which they act.

Let the lines AB, AD, AE, (fig. 5) represent the three forces acting upon the body A, in those directions, and by that means keeping it at rest in the point A. Then the forces EA and DA will be equivalent to BA, otherwise the body would be put into motion by them (*contra Hypoth.*) But these forces are also equivalent to AC, consequently AC may be made use of to express the force AB, and EC, which is parallel and equal to AD, may express the force AD, while AE expresses its own: but ACE is a triangle whose sides are all parallel to the given directions; therefore the sides of this triangle will express the relation of the forces by which the body is kept at rest.

Bridge of COMMUNICATION. See the article BRIDGE.

Lines of COMMUNICATION, in military matters, trenches made to continue and preserve a safe correspondence between two forts or posts; or at a siege, between two approaches, that they may relieve one another.

COMMUNION, in matter of religion, the being united in doctrine and discipline; in which sense of the word, different churches are said to hold communion with each other.

COMMUNION is also used for the act of communicating in the sacrament of the eucharist, or the Lord's supper.

COMMUNITY, a society of men living in the same place, under the same laws, the same regulations, and the same customs.

COMMUTATION, in astronomy, is the angular distance between the sun's true place seen from the earth, and the place of a planet reduced to the ecliptic. This angle of commutation is found by subtracting the sun's true place from the heliocentric place of the planet. See *HELIOCENTRIC*.

COMMUTATION, in law, the change of a penalty

or punishment from a greater to a less; as when death is commuted for banishment, &c.

COMPACT, in physiology, is said of bodies which are of a close, dense, and heavy texture, with few pores, and they very small.

COMPANION, in naval architecture, a sort of wooden porch raised over the stair-case which leads from the quarter-deck of a merchant-ship down to the cabin or apartment of the master. See **CABIN**.

COMPANY, in general, denotes a number of people met together in the same place, and about the same design. With respect, however, to matters of pleasure or division, instead of company, we make use of the terms party, or match.

COMPANY, in a commercial sense, is a society of merchants, mechanics, or other traders, joined together in one common interest.

COMPANY, in military affairs, a small body of foot, commanded by a captain, who has under him a lieutenant and ensign.

The number of centinels, or private soldiers in a company, may be from 50 to 80; and a battalion consists of thirteen such companies, one of which is always grenadiers, and posted on the right: next them stand the eldest company, and on the left the second company; the youngest one being always posted in the center.

Companies not incorporated into regiments are called irregulars, or independent companies.

Rule of COMPANY, in arithmetic, the same with Fellowship. See **FELLOWSHIP**.

COMPARATES, *Comparata*, among logicians, denote the terms of a comparison, or the subjects compared to each other. See the article **COMPARISON**.

COMPARATIVE, in general, denotes something that is compared to another. Thus,

COMPARATIVE ANATOMY, is that branch of anatomy which considers the secondary objects, or the bodies of other animals; serving for the more accurate distinctions of several parts, and supplying the defect of human subjects.

It is otherwise called the anatomy of beasts, and sometimes zootomy; and stands in contradistinction to human anatomy, or that branch of the art which considers the human body, the primary object of anatomy. See **ANATOMY**.

COMPARATIVE DEGREE, among grammarians, that between the positive and superlative degrees, expressing any particular quality above or beneath the level of another.

COMPARISON, in a general sense, the consideration of the relation between two persons or things, when opposed and set against each other, by which we judge of their agreement or difference, and find out wherein the one has the advantage of the other.

COMPARISON of Ideas, among logicians, that operation of the mind whereby it compares its ideas

one with another, in regard of extent, degree, time, place, or any other circumstance, and is the ground of relations. This is a faculty which the brutes seem not to have in any great degree. See **IDEA** and **RELATION**.

COMPARISON, in grammar, the inflection of the comparative degree. See the article **COMPARATIVE**.

COMPARISON, in rhetoric, a figure that illustrates and sets off one thing, by resembling and comparing it with another, to which it bears a manifest relation and resemblance, as the following figure in Shakespear:

"She never told her love,

"But let Concealment, like a worm in th' bud,

"Feed on her damask cheek: She pined in thought,

"And sat, like Patience on a monument,

"Smiling at Grief."

COMPARTITION, in architecture, denotes the useful and graceful disposition of the whole ground-plot of an edifice, into rooms of office, and of reception or entertainment.

COMPARTMENT, or **COMPARTIMENT**, in general, is a design composed of several different figures, disposed with symmetry, to adorn a parterre, a ceiling, &c.

COMPASS, or *Mariners COMPASS*, an instrument whereby the ship's course is determined.

This instrument, which is a representation of the horizon, is a circle divided into 32 equal parts, by right lines drawn from the center to the circumference, called points, or rumbs, being also divided into 360 equal parts, or degrees; and consequently the distance between, or angle formed by, any two rumbs, is equal to 11° , $15'$. The four principal of these rumbs are called the cardinal points, and take their names from the places to which they tend, viz. that which extends itself under the meridian, pointing towards the north, is called north; and its opposite one, pointing towards the south, is called south; that which is towards the right-hand, the face being directed north, is termed east; and its opposite, west. The names of the others are compounded of those, according to their situation.

The compass being of the utmost consequence to navigation, it is reasonable to expect that the greatest attention should be used in its construction, and every attempt to improve it carefully examined, and, if proper, adopted. But so careless are the generality of commanders of this most useful instrument, that almost all the compasses used on board merchant-ships have their needles formed of two pieces of steel wire, each of which is bent in the middle, so as to form an obtuse angle; and their ends, being applied together, make an acute one; so that the whole represents the form of a lozenge; in the center of which, and of the card,

is

is placed the brass cap. Now, if we examine a number of these cards, we shall rarely, if ever, find them all in the same direction, but they will all vary more or less, not only with regard to the true direction, but from one another.

These irregularities are owing to the structure of the needle; for the wires of which it is composed are only hardened at the ends; now, if these ends are not equally hard, or if one end be hardened up higher than the other, when they come to be put together, in fixing them to the card, that end which is hardest will destroy much of the virtue of the other; by which means the hardest end will have the most power in directing the card, and consequently make it vary toward its own direction: and, as the wires are disposed in the form of a lozenge, these cards can have but little force, so that they will often, when drawn aside, stand at the distance of several degrees on either side the point from whence they are drawn: for all magnetical bodies receive an additional strength by being placed in the direction of the earth's magnetism, and act proportionably less vigorously when turned out of it: wherefore, when these kind of needles are drawn aside from their true point, two of the parallel sides of the lozenge will conspire, more directly than before, with the earth's magnetism; and the other two will be less in that direction: by which means the two sides will very much impede its return; and the two latter will have that impediment to overcome, as well as the friction, by their own force alone.

To remove these inconveniencies, some needles are made of one piece of steel, of a spring temper, and broad towards the ends, but tapering towards the middle, where a hole is made to receive the cap. At the ends they terminate in an angle, greater or less, according to the skill or fancy of the workman. These needles, though infinitely preferable to the other, are, however, far from being perfect; for every needle of this form hath six poles instead of two, one at each end, two where it becomes tapering, and two at the hole in the middle: this is owing to their shape; for the middle part being very slender, it has not substance enough to conduct the magnetic stream quite through, from one end to the other: all these poles appear very distinctly, when examined with a glass that is sprinkled over with magnetic sand. This circumstance, however, does not hinder the needle from pointing true; but as it has less force to move the card than when the magnetic stream moves in large curves from one end to the other, it is certainly an imperfection.

These inconveniencies induced the ingenious Dr. Knight to contrive a new sea-compass, which is now used on board all the ships of war. The needle in this instrument is quite straight, and square at the ends; and consequently has only two poles, though about the hole in the middle, the curves are a little confused. Needles of this construction,

after vibrating a long time, will always point exactly in the same direction; and if drawn ever so little on one side, will return to it again, without any sensible difference. We may therefore conclude, that a regular parallelopiped is the best form for a needle, as well as the simplest, the holes for the caps being as small as possible.

And as the weight should be removed to the greatest distance from the center of motion, a circle of brass, of the same diameter of the card, may be added, which will serve also to support the card, which may then be made of thin paper, without any thing to stiffen it. This ring being fixed below the card, and the needle above it, the center of gravity is placed low enough to admit of the cap being put under the needle, whereby the hole in the needle becomes necessary.

In order to render the above instructions more plain and easy to be understood, we have given a view of the several parts (Plate XXXVI.) where *fig. 6.* is the card, with the needle *KL*, and its cap *M*, fixed upon it, being one third of the diameter of the real card.

Fig. 7. is a perspective view of the backside of the card, where *AB* represents the turning down of the brass edge, *C* the under part of the cap, *D* and *E* two sliding weights to balance the card, and *F*, *G*, two screws that fix the brass edge, &c. to the needle.

Fig. 8. is the pedestal that supports the card, containing a sewing-needle, fixed in two small grooves to receive it, by means of the collet *C*, in the manner of a port-crayon. *D*, the stem, is filed into an octagon, that it may be the more easily unscrewed.

AZIMUTH COMPASS. See the article **AZIMUTH Compass**.

COMPASS DIALS, are small horizontal dials, fitted in brass or silver boxes, for the pocket, to shew the hour of the day, by the direction of a needle, that indicates how to place them right, by turning the dial about till the cock or style stands directly over the needle, and points to the northward: but these can never be very exact, because of the variations of the needle itself.

COMPASS-SAW. See the article **SAW**.

COMPASSES, or *Pair of COMPASSES*, a mathematical instrument for describing circles, measuring figures, &c.

Beam COMPASSES consist of a long branch, or beam, carrying two brass cursors, the one fixed at one end, the other sliding along the beam, with a screw to fasten it on occasion.

To the cursors may be screwed points of any kind, whether steel, for pencils, or the like. It is used to draw large circles, to take great extents, &c.

Caliber COMPASSES. See **CALIBER**.

Clockmaker's COMPASSES are joined like the common

mon compasses, with a quadrant, or how, like the spring compasses; only of different use, serving here to keep the instrument firm at any opening. They are made very strong, with the points of their legs of well tempered steel, as being used to draw lines on paste-board or copper.

Cylindrical and Spherical COMPASSES, consist of four branches, joined in a center, two of which are circular, and two flat, a little bent on the ends: their use is to take the diameter, thickness, or caliber, of round or cylindric bodies; such as cannons, pipes, &c.

For the method of using them, see the article *CALIBER COMPASSES*.

Elliptic COMPASSES consist of a cross ABGH, (Plate XXXIV. fig. 4.) with grooves in it, and an index CE, which is fastened to the cross by means of dove-tails at the points CD, that slide in the grooves; so that when the index is turned about, the end E will describe an ellipsis, which is the use of these compasses.

German COMPASSES have their legs a little bent outwards, towards the top; so that when shut, the points only meet.

Lapidary's COMPASSES are a piece of wood, in form of the shaft of a plane, cleft at top, as far as half its length: with this they measure the angles, &c. of jewels and precious stones, as they cut them.

There is in the cleft a little brass rule, fastened here at one end by a pin; but so that it may be moved in the manner of a brass level: with this kind of square they take the angles of the stones, laying them on the shaft as they cut them.

Proportional COMPASSES are such as have two legs, but four points, which, when opened, are like a cross, as not having the joint at the end of the legs like common compasses: some of these have fixed joints, others moveable ones; upon the legs of the latter of which are drawn the lines of chords, sines, tangents, &c.

Their use is to divide lines and circles into equal parts; or to perform the operations of the sector at one opening of them.

COMPENDIUM, in matters of literature, denotes much the same with epitome, or abridgement. See *ABRIDGMENT*.

COMPENSATION, in a general sense, an action whereby any thing is admitted as an equivalent to another.

COMPENSATION, in the civil law, a sort of right, whereby a debtor, sued by his creditor for the payment of a debt, demands that the debt may be compensated with what is owing him by the creditor, which in that case is equivalent to payment.

COMPLAINANT, in law, the same with plaintiff. See the article *PLAINTIFF*.

COMPLEMENT, in astronomy, is an arch of

a circle, comprehended between the place of a star above the horizon and the zenith, which is commonly called the star's zenith distance, or complement of altitude.

COMPLEMENT of the Course, in navigation, is the number of points, or degrees, minutes, and seconds that the course wants of eight points, or 90 degrees.

COMPLEMENT, in geometry, is what remains of a quadrant of a circle, after some parts has been taken away; or it is that part which in any angle or arch of a circle is wanting to make it a quadrant or 90 degrees.

The sine of the complement of any arch is called the co-sine, and that of the tangent, the co-tangent, &c.

COMPLEMENT of the Curtin, in fortification, is that part of which makes the demigorge. See the articles *CURTIN* and *DEMIGORGE*.

COMPLEMENT of the Line of Defence, is the remainder of the line of defence, after the angle of the flank is taken off. See the articles *ANGLE* and *DEFENCE*.

COMPLEMENTS in a Parallelogram, are the two smaller parallelograms GAE, FCE, (Plate XXXIV. fig. 5.) made by drawing two right lines GE, and FE, through the point E, in the diagonal; and parallel to the sides AB, BC, of a parallelogram ABCD.

COMPLEX Ideas, in logic, are such as are compounded of several simple ones. See the articles *TERM* and *IDEA*.

COMPLEX Proposition is either that which has at least one of its terms complex, or such as contains several members, as casual propositions: or it is several ideas offering themselves to our thoughts at once, whereby we are led to affirm the same thing of different objects, or different things of the same object. Thus, *God is infinitely wise, and infinitely powerful*. In like manner, in the proposition, *Neither kings nor people are exempt from death*.

COMPLEX Term, in logic, is that which requires more than one word to signify one thing; or where one word implies several things.

COMPLEXUS, in anatomy, a broad and pretty long muscle, lying along the back-part and side of the neck: it is fixed below to the vertebrae of the neck, and above to the upper transverse line of the os occipitis. There is one of these on each side; and both acting together, they pull the head directly backwards; whereas, if only one acts, it draws the head obliquely back.

COMPLEXUS MINOR, in anatomy, a narrow, long, and slender muscle, lying along the inside of the neck, and otherwise called *maistoidæus lateralis*. See the article *MUSCLES*.

COMPLICATION, in general, denotes the blending, or rather interweaving, of several different things together: thus a person afflicted with several

several disorders at the same time, is said to labour under a complication of diseases.

COMPONED, **COMPONE**, or **GORONY**, in heraldry, is said of a bordure made up of angular parts, or chequers, of two different colours.

COMPOSITE, in general, denotes something compounded, or made up of several others united together. Thus,

COMPOSITE NUMBERS is one that may be divided by some one less than the composite itself, but greater than unity, as 4, 6, 8, 9, 10, &c.

COMPOSITE ORDER, in architecture, the last of the five orders of columns; so called because its capital is composed out of those of the other columns, borrowing a quarter-round from the Tuscan and Doric, a row of the leaves from the Corinthian, and volutes from the Ionic. Its cornice has simple modillions or dentils. It is also called the Roman or Italic order, as having been invented by the Romans. By most authors it is ranked after the Corinthian, either as being the next richest, or the last invented.

Scamozzi, and after him M. le Clerc, make the column of this order nineteen modules and a half, being less by half a module than that of the Corinthian, as in effect the order is less delicate than the Corinthian. Vignola makes it twenty, which is the same with that of his Corinthian: but Serlio, who first formed it into an order by giving it a proper entablature and base, and after him M. Perrault, raise it still higher than the Corinthian. See **ORDER**.

For the parts of this order, see the articles **BASE**, **CAPITAL**, **COLUMN**, **ENTABLATURE**, **FRIEZE**, **PEDESTAL**, &c.

COMPOSITION, *Compositio*, in a general sense, the uniting or putting together several things, so as to form one whole, called a compound.

COMPOSITION of Ideas, an act of the mind, whereby it unites several simple ideas into one conception, or complex idea.

COMPOSITION, in grammar, the joining of two words together; or prefixing a particle to another word, to augment, diminish, or change its signification. See the article **WORD**.

COMPOSITION, in logic, a method of reasoning, whereby we proceed from some general self-evident truth, to other particular and singular ones.

COMPOSITION, in music, the art of disposing musical sounds into airs, songs, &c. either in one or more parts, to be sung by a voice, or played on instruments. See the articles **MUSIC** and **SONG**.

COMPOSITION, in oratory, the coherence and order of the parts of a discourse.

COMPOSITION, in painting, consists of two parts, invention and disposition; the first is the choice of the objects which are to enter into the composition of the subject the painter intends to execute, and is either simply historical or allegorical.

The other very much contributes to the perfection and value of a piece of painting.

COMPOSITION, in commerce, a contract between an insolvent debtor and his creditors, whereby the latter accept of a part of the debt in compensation for the whole, and give a general acquittance accordingly.

COMPOSITION, in printing, commonly termed **composing**, the arranging of several types, or letters, in the composing stick, in order to form a line; and of several lines ranged in order in the galley, to make a page; and of several pages, to make a form.

COMPOSITION of Motion, or **FORCE**, in mechanism, is an assemblage of several directions of motion resulting from powers acting in different, though not in opposite lines.

The change of motion is proportionable to the moving force impressed, and is made according to the right line in which that force is impressed. It is well known, that if any force generate any motion, a double or triple force will generate twice or thrice as much. But the alteration in respect of the direction of the motion, is a compound affair.

Let A be a body (Plate XXXIV. fig. 6.) impelled in the direction CD, by a body C, with such force as shall cause it to be uniformly over the space AD, in a second of time: at the same instant, let it receive a stroke by another body F, in the direction FB, with such a force as shall cause it to pass over the space AB in the same time.

Now, it is evident, the body A cannot move in both these directions; and, therefore, will not move in either, but in a direction compounded of both, which may be thus demonstrated. Describe DE, parallel to FB; then, though the action of F prevents the body from proceeding in the right-line AD, yet it can no ways alter its velocity of approaching to the line DE, in the given time, by virtue of the force impressed by C. At the end, therefore, of a second of time, the body A will be somewhere in the line DE; by the same way of reasoning, it will, at the end of the same time, be found somewhere in the line BE, parallel to AD, and therefore in the concurrence of both, in the point E. Its cause then, is the line AE, which, by the first law of motion, is a right line. See **LAWS of Motion**.

Hence appears the method of compounding a direct force AE, out of any oblique force AD and DE; and, on the contrary, of resolving any direct force AE into two other oblique forces, by the two sides of a parallelogram; for the direct force will be represented by the diagonal, and the oblique by the sides AD and DE. The truth of this theory may be proved by experiment in the following manner.

Let the body A be drawn with a weight of three ounces in the direction AD, and by another of two ounces in the direction AB; then make AD to

AB

AB as three to two, and compleat the parallelogram ADBE, and draw the diagonal (as in Plate XXXIV. fig. 7.) AE, which will measure four upon the same scale, (when the angle DAB is of a certain magnitude) which shews the body A in the same circumstance, as if it had been drawn by a four ounce weight in the direction AE; and this is proved true, by causing a body G of four ounces to draw the body A the contrary way, viz. from A to G; for then the body A will be at rest, or in equilibrio with all the forces.

COMPOSITION of Proportion. See **PROPORTION**.

COMPOST, in husbandry and gardening, several sorts of soils, or earthy matter, mixed together, in order to make a manure for assisting the natural earth in the work of vegetation, by way of amendment or improvement.

Composts are various, and ought to be different, according to the different nature or the quality of the soils which they are designed to meliorate, and according as the land is either light, sandy, loose, heavy, clayey, or cloddy. A light, loose land requires a compost of a heavy nature, as the scouring of deep ditches, ponds, &c. so, on the other hand, land that is heavy, clayey, or cloddy, requires a compost of a more sprightly and fiery nature, that will insinuate itself into the lumpish clods, which, if they are not thus managed, would very much obstruct the work of vegetation. See **CLAY**, &c.

The great use of composts is for such plants as are preferred in pots, or tubs; or sometimes it is used for small beds, or borders of flower-gardens; but it is too expensive to make composts for large gardens, where a great quantity of soil is required. In making of composts, great care should be had that the several parts are properly mixed together, and not to have too much of any one sort thrown together.

COMPOSTO, in music, means compounded or doubled, as a fifteenth is an octave doubled, or an octave is compounded of a fifth and a fourth.

COMPOUND, in a general sense, an appellation given to whatever is composed or made up of different things: thus we say, a compound word, compound sound, compound taste, compound force, &c. See the articles **WORD**, **SOUND**, &c.

COMPOUND FLOWER, one consisting of several distinct lesser flowers, or corollulæ, each furnished with a style, stamina, &c. See **FLOWER**.

The corollulæ are of two kinds, viz. tubulated and ligulated: the tubulated ones are always furnished with a campanulated limb, divided into four or five segments; whereas the ligulated corollulæ have only a flat, linear limb, terminated by a single point, or by a broader extremity, divided into three or five segments.

The plants with compound flowers are extremely

numerous, forming a class by themselves, called by Linnæus, *syngenesia*. See the article **SYNGENESIA**.

COMPOUND-INTEREST. See the article **INTEREST**.

COMPOUND-MOTION, is that which is produced by several forces conspiring together in such a manner, that the direction of one is not contrary to the direction of the other; as when the radius of a circle moves about the center at the same time a point be conceived to go forwards along it. See **COMPOSITION of Motion**.

COMPOUND NUMBERS, PENDULUM, QUANTITIES, RATIO, &c. See **NUMBERS, PENDULUMS, &c.**

COMPOUNDER, in general, denotes one who compounds several things together.

COMPREHENSION, in logic, the same with apprehension. See **APPREHENSION**.

COMPREHENSION, or **SYNECDOCHE**, a trope or figure in rhetoric, which puts the name of the whole for a part, or of a part for the whole; a general for a particular of the same kind; or a particular for a general. By this trope a round and certain number is often set down for an uncertain one.

COMPRESS, in surgery, a bolster of soft linen cloth, folded in several doubles, frequently applied to cover a plaster, in order not only to preserve the part from the external air, but also the better to retain the dressings or medicines.

COMPRESSED LEAF, among botanists, one with a mark or impression on both sides. See **LEAF**.

COMPRESSOR, in anatomy, a muscle of the face, more usually known by the name of *elevator alæ nasi*.

COMPROMISE, a treaty, or contract, whereby two contending parties establish one or more arbitrators, to judge of and terminate their difference in an amicable way.

COMPTROLLER, or **CONTROLLER**. See the article **CONTROLLER**.

COMPUNCTION, in theology, an inward grief of mind for having offended God.

COMPURGATOR, in law, a person that by oath justifies or clears another's innocence.

COMPUTATION, in a general sense, the manner of estimating time, weights, measure, monies, or quantities of any kind.

COMPUTATION in Mathematicks, is used in the same sense as calculation. See **CALCULATION**.

CONARION, or **CONOIDES**, a name for the pineal-gland, a small gland about the bigness of a pea, placed in the upper part of that hole in the third ventricle of the brain, called the anus, and tied by some fibres to the nates. See **BRAIN**.

CONATUS, in a *Body of Motion*, is that disposition

tion or aptitude to go on in a right line, if not prevented by other causes, the same as attraction and gravitation without motion.

CONATUS is likewise a term used in mathematics to imply the endeavour any natural body that moves circular has to fly off, or recede from the center of its motion.

CONCAVE, or CONCAVITY, are terms used to signify the hollowness of any thing.

CONCAVE GLASS, or LENS, is one that is flat on one side and ground hollow on the other, but usually spherical. This by some is called a plano concave, and if this be concave or hollow on both sides it is called a double concave.

An object seen through a concave glass, or lens, appears nearer, smaller, and less bright than with the naked eye.

Thus, let AB, (Plate XXXIV. fig. 8.) be the object, CD the pupil of an eye, and EF the lens. Now, as it is the property of a lens, of this form, to render diverging rays more so, and converging ones less so, the diverging rays GH, GI, proceeding from the point G, will be made to diverge more, and so to enter the eye, as from some nearer point *g*; and the rays AH, BI, which converge, will be made to converge less, and to enter the eye sooner as from the points *a* and *b*; wherefore the object will appear in the situation *a, g, b*, less and nearer than without the lens.

But as the rays which proceed from G, are rendered more diverging, some of them will be made to pass by the pupil of the eye, which otherwise would have entered it, and therefore each point of the object will appear less bright. See FOCUS, LENS, and MIRROR.

CONCENTRATION, in general, signifies the bringing things nearer a center. Hence the particles of salt, in sea-water, are said to be concentrated; that is, brought nearer each other, by evaporating the watery part: thus, also, wine is said to be concentrated, when its watery parts are separated in form of ice by frost.

CONCENTRIC, in mathematics, something that has the same common center with another: it stands in opposition to excentric.

CONCEPTACULUM, among botanists, a kind of pericarpium, composed of soft and less rigid valves, and containing only one cavity.

CONCEPTION, among physicians, &c. denotes the first formation of an embryo in the womb of its parent, who from that time becomes pregnant. See GENERATION and PREGNANCY.

Immaculate CONCEPTION, a festival in the Romish church, observed on the 8th of December, in commemoration of the holy virgin's having been conceived and born immaculate, or without original sin.

CONCEPTION of our Lady, a religious order in Portugal, founded in the XVth century.

CONCEPTION, in logic, the same with apprehension. See APPREHENSION.

CONCERT, or CONCERTO, in music, a number or company of musicians, playing or singing the same piece of music or song at the same time.

CONCERTANTE, those parts of a piece of music that sing or play throughout the whole piece, either alone, or accompanied, to distinguish those parts that play now and then in particular places.

CONCERTATO intimates the piece of music to be composed in such a manner, as that all the parts may have their recitatives, be it for two, three, four, or more voices or instruments.

CONCERTO GROSSI, the grand chorus of a concert, or those places where all the several parts perform or play together.

CONCESSI, in law, a term frequently used in conveyances. Its effect is to create a covenant, as *dedi* does a warranty.

CONCESSION, in rhetoric, a figure, whereby something is freely allowed, that yet might bear dispute; to obtain something that one would have granted to him, and which he thinks cannot fairly be denied, as in the following concession of Dido, in Virgil:

“The nuptials he disclaims, I urge no more;
“Let him pursue the promised Latian shore.
“A short delay is all I ask him now;
“A pause of grief, an interval from woe.”

CONCHA, a genus of bivalve shells, the animal inhabiting which is called tethys. See the article TETHYS.

CONCHA, in anatomy, the larger cavity of the external ear, situated before the meatus auditorius, or passage into the internal ear.

CONCHOID, or CONCHILIS, in geometry, a curve line, which always approaches nearer a straight line, to which it is inclined, but never meets it.

It is described thus: draw a right line BD (Plate XXXIV. fig. 9.) and another AC, perpendicular to it to E; draw any number of right lines, as CM, CM, cutting BD in Q; make QM = QN = AE = EF; the curve wherein the points M, M, are found, is the *conchilis*, or *conchois prima*; so called by its inventor Nicomedes. The others, wherein the points N, N, are found, is the *conchois secunda*; the right line BD the rule, the point C the pole. The inventor also contrived an instrument, whereby the first conchois may be described mechanically: thus, in the rule AD, (fig. 10.) is a channel or groove cut, so as a smooth nail, firmly fixed in the moveable rule CB, in the point F, may slide freely within it: into the rule EG is fixed another nail in K, for the moveable rule CB to slide upon.

If then the rule BC be moved, as that the nail F passes along the canal AD, the style or point in C will describe the first conchoid.

Now let AP = *x*, AE = *a*, PE = MR = *a*

x ; wherefore as x increases, $a - x$ or MR will decrease, and therefore the curve continually approaches nearer to the rule BD .

In the same manner it appears that the right line NO must continually decrease, and therefore that the second conchoid also must continually approach nearer the rule.

Now as between each conchoid and the right line BD , there will still be the right line QM or QN , equal to AE ; neither of the conchoids can concur with the right line BD , consequently D is an asymptote of each conchoid.

Put $b = CE$, $a = EA = MQ$, $CQ = x$, $MR = y$; then by the similar triangles CEQ , QRM , we have $CE : CQ :: MR : MQ$, that is, $b : x :: y : a$, whence $ba = xy$.

Sir Isaac Newton, in the latter part of his Universal Arithmetick, tells us, that the conchoid was used by Archimides, and other ancients, in the construction of solid problems; and he himself prefers it before other curves, or even the conic sections, in the construction of cubic and biquadratic equations, on account of its simplicity and easy description, shewing therein the manner of their construction by help of it.

CONCHYLIA, a general name for all kinds of petrified shells, as limpets, cochlea, nautili, conchæ, lepadæ, &c.

CONCINNOUS INTERVALS, in music, are such as are fit for music, next to, and in combination with, concords; being neither very agreeable nor disagreeable in themselves, but having a good effect, as by their opposition they heighten the more essential principles of pleasure; as by their mixture and combination with them, they produce a variety necessary to our being better pleased.

CONCINNOUS SYSTEM, in music. A system is said to be concinnous, when its parts, considered as simple intervals, are concinnous; and are besides placed in such an order between the extremities, as that the succession of sounds, from one extreme to the other, may have an agreeable effect.

CONCLAVE, the place in which the cardinals of the Romish church meet, and are shut up, in order to the election of a pope.

CONCLAVE is also used for the assembly or meeting of the cardinals shut up, for the election of a pope.

CONCLUSION, in logic, the consequence or judgment drawn from what was asserted in the premises; or the previous judgments in reasoning, gained from combining the extreme ideas between themselves. See the article **SYLLOGISM**.

CONCOCTION, in medicine, the change which the food undergoes in the stomach, &c. to become chyle. See **CHYLE**, **CHYLIFICATION**, and **DIGESTION**.

CONCOMITANT, in theology, something that accompanies or goes along with another; as

concomitant grace is that which God affords us, during the course of our actions, to enable us to perform them; and according to the Romish divines, to render them meritorious.

CONCORD, in grammar, that part of construction called syntax, in which the words of a sentence agree; that is, in which nouns are put in the same gender, number, and case; and verbs in the same number and person with nouns and pronouns.

CONCORD, in music, the relation of two sounds that are always pleasing to the ear, whether applied in consonance or in succession.

If two simple sounds have such a relation, or difference of tune, as that, when mixed together, they form a compound sound, which agreeably affects the ear, that relation is denominated concord; and whatever two sounds agree in consonance, the same will follow each other agreeably, or be pleasing in succession. The reverse of a concord is a discord, being all the relations or differences of tune that are grating to the ear.

Concord and harmony are, in fact, the same thing, though by custom they are applied differently, harmony expressing the agreement of a greater number of sounds than two in consonance; besides, harmony always implies consonance; but concord is sometimes applied to succession, though never but when it will make a pleasing consonance: whence it is, that Dr. Holder, and some others, use the word consonance for what is called concord.

Unisonance being the relation of equality between the two sounds, all unisons are concords, in the first degree: but an interval, being a relation of inequality between two sounds, becomes a concord or discord, according to the variety of that particular relation: Mr. Malcolm thinks, that as the word implies agreement, it is applicable to unison in the first degree.

The differences of tune take their rise from the different proportions of the vibrations of a sonorous body, that is, of the velocity of those vibrations in their recourses; the more frequent those recourses are, the more acute is the tune, & *vice versa*. But the essential difference between concord and discord lies more remote: there does not appear any natural aptitude in two sounds of a concord to give a pleasing sensation, more than in two of a discord; these different effects must be resolved into the divine will.

We know from experience what proportions of tune are pleasing, and what not; and we know likewise, how to express the difference of tune by the proportion of numbers; we know what is pleasing, though we do not know why: for instance, we know that the ratio of 1 : 2 constitutes concord, and 6 : 7 discord; but on what original system pleasing or displeasing ideas are connected with those relations,

relations, and their proper influence upon one another, is entirely above our reach.

We know that the following ratio's of the lengths of chords are concord 2 : 1, 3 : 2, 4 : 3, 5 : 4, 6 : 5, 5 : 3, 8 : 5; that is, by taking any chord for a fundamental, represented by one, the following divisions thereof will be all concords with the whole,

as $\frac{1}{2}, \frac{2}{3}, \frac{3}{4}, \frac{4}{5}, \frac{5}{6}, \frac{5}{8}$. So that the characteristic of concords and discords must be looked for in these numbers, expressing the intervals of sound: not abstractly, but as exhibiting the number of vibrations.

Now unisons are in the first degree of concord, or have the most perfect agreement in tune; and therefore have something accessory to that agreement which is more or less to be found in every concord: but it is not true, that the nearer two sounds approach to an equality of tune, the more agreement they have; therefore it is not in the equality or inequality of the numbers that this agreement consists.

Farther, if we consider the number of vibrations made in any given time by two chords of equal time, they are, on the principle already laid down, equal; and therefore the vibrations of the two chords commence together as frequently as possible; that is, they coincide at every vibration, in the frequency of which coincidence, and of the undulations of the air occasioned thereby, it is that the difference of concord and discord must be fought.

Now, the nearer the vibrations of two strings approach to a coincidence as frequent as possible, the nearer they should approach that condition, and consequently the agreement of unisons, as is confirmed from experience.

If we take the natural series, 1, 2, 3, 4, 5, 6, and compare each number to the next, as expressing the number of vibrations of two chords in the same time, whose lengths are reciprocally as those numbers; the rule will be found exact; for 1 : 2 is best, then 2 : 3; after 6 the consonance is insufferable, as the coincidences are too rare; though there are other ratios that are agreeable, besides those found in that continued order, namely, 3 : 5 and 5 : 8, which, with the preceding five, are all the concordant intervals within, or less than an octave, or 1 : 2; that is, whose acutest term is greater than half the fundamental.

On this principle 3 : 5 will be preferable to 4 : 5, because, being equal in the number of vibrations of the acuter term, there is an advantage on the side of the fundamental in the ratio 3 : 5, where the coincidence is made at every third vibration of the fundamental, and every fifth of the acute term: in like manner the ratios 5 : 8 is less perfect than 5 : 6; because though the vibrations of each fundamental, that go to one coincidence, are equal, yet, in the

ratio 5 : 6, the coincidence is at every sixth of the acute term, and only at every eighth in the other.

Thus there is a rule for judging of the preference of concords from the coincidence of their vibrations, as in the following table.

Ratios, or Vibrations.

	Grave Term.	Acute Term.	Coincid.
Unison	1	1	
Octave, 8ve,	2	1	60
Fifth, 5th.	3	2	30
Fourth, 4th.	4	3	20
Sixth, gr.	5	3	20
Third, gr.	5	3	15
Third, lesser.	6	5	12
Sixth, lesser,	8	5	12
	Grave Lengths.	Acute	

Though this order be settled by reason, it is confirmed by the ear; so that, upon this foot, concords must be the more perfect, as they have the greater number of coincidences, with regard to the number of vibrations in both chords; and where the coincidences are equal, the preference will fall on that interval, whose acutest term has fewest vibrations to each coincidence: which rule is, however, in some cases contrary to experience; and yet is the only rule hitherto discovered.

F. Merfenne, it is true, after Kircher, gives another standard for settling the comparative perfection of intervals, with regard to the agreement of their extremes in tune.

The perception of concordance, say they, is nothing but the comparing of two or more different motions, which in the same time affect the auditory nerve: now we cannot certainly judge of any consonance till the air be as often struck in the same time by two chords, as there are units in each member expressing the ratio of that concord; as for instance, we cannot perceive a fifth, till two vibrations of the one chord, and three of the other, are performed together, which chords are at length as 3 to 2: so that those concords are most simple and agreeable, which are generated in the least time; and those, on the contrary, the most compound and grating, which are produced in the longest time.

For example, let 1, 2, 3, be the lengths of three chords; 1 : 2 is an octave; 2 : 3 a fifth; and 1 : 3 an octave and fifth compounded, or a twelfth. The vibrations of chords being reciprocally as their lengths, the chord 2 will vibrate once, while the chord 1 vibrates twice, and then exist an octave; but the twelfth does not yet exist, because the chord 3 has not vibrated once, nor the chord 1 thrice, which is necessary to form a twelfth.

Again,

Again, to generate a fifth, the chord 2 must vibrate thrice, and the chord 3 twice; in which time the chord 1 will have vibrated 6 times; and thus the octave will be thrice produced, while the twelfth is only produced twice; the chord 2 uniting its vibrations sooner with the chord 1, than with the chord 3; and they being sooner consonant than the chord 1 or 2 with that of 3.

But this rule, upon examining it by other instances, Mr. Malcolm has shewn to be defective, as it does not answer in all positions of the intervals with respect to each other; but in a certain order required: and there being no rule, as to the order, to make this standard tally with experience in every case; we are at last left to determine the degrees of concord by experience and the ear.

So that the whole may be summed up in this definition: concord is the result of a frequent union, or coincidence of the vibrations of two sonorous bodies, and consequently of the undulating motions of the air, which, arising from these vibrations, are similar and proportionable to them; which coincidence, the more frequent it is, with regard to the number of vibrations of both bodies, performed in the same time, *ceteris paribus*, the more perfect is that concord: till the unfrequency of the coincidence, in respect of one or both the motions, commences discord.

Mr. Carre, in the *Memoirs of the Royal Academy*, lays down a general proposition to determine the proportion of cylinders that are to form the concords of music; namely, that the solid cylinders, whose sounds produce those concords, are in a triplicate and inverse ratio of that of the numbers which denote the same concords.

For instance, suppose two cylinders, the diameters of whose bases and lengths are as 3 to 2, their solidities will be in the ratio of 27 to 8, which is the triplicate ratio, or as the cube of 3 to that of 2; consequently the sounds of those two cylinders will produce a fifth, as expressed by those numbers; and that the biggest and longest will give the grave sound, and the smallest the acute: and so of all the rest.

Concords are divided into original, or simple and compound. A simple concord is that whose extremes are less remote than the sum of any other two concords. A compound concord is equal to two or more concords.

Other musical writers state the division in this manner; an octave is 1:2, and all the inferior concords above mentioned are simple ones: and all greater than an octave are compound concords; as consisting of, and being equal to, the sum of one or more octaves, and some single concord less than an octave; and are usually, in practice, called simple concords.

As to the composition and relations of original concords, by applying to them the rules of the ad-

dition and subtraction of intervals, they will be divided into simple and compound, according to the more general motion: as,

$$\left. \begin{array}{l} 5:6 \text{ a 3d lefs } | 4^{\text{th}} \quad | 3^{\text{d}} \text{ g. and } 3^{\text{d}} \text{ l.} \\ 4:5 \text{ a 3d gr. } | 6^{\text{th}} \text{ lefs } | 4^{\text{th}} \text{ and } 3^{\text{d}} \text{ l.} \\ 3:4 \text{ a 4th } | 6^{\text{th}} \text{ gr. } | 6^{\text{th}} \text{ gr.} \end{array} \right\} \text{ of } \left\{ \begin{array}{l} 5^{\text{th}} 4^{\text{th}} \text{ or } 6^{\text{th}} \\ \text{gr. } 3^{\text{d}} \text{ lefs or} \\ \quad 3^{\text{d}} \text{ gr. } 3^{\text{d}} \text{ l.} \\ \quad 4^{\text{th}}. \end{array} \right.$$

The octave is not only the first concord in point of perfection, the agreement of whose extremes is greatest, and the nearest to unison; so that, when sounded together, it is impossible to perceive two different sounds; but it is likewise the greatest interval of the seven original concords; and, as such, contains all the lesser, which derive their sweetness from it, as they more or less directly rise out of it, and which gradually decrease from the octave to the lesser sixth, having but a small degree of concord.

The manner in which those lesser concords are found in the octave, shews their mutual dependences. For, taking an harmonical and arithmetical mean betwixt each extreme, and the most distant of the two means last found, to wit, betwixt the lesser extreme and the first arithmetical mean, and betwixt the greater extreme and the first harmonical mean, we have all the lesser concords. Thus, if betwixt 360 and 180, the extremes of the octave, you take an arithmetical mean, it is 270, and an harmonical one is 240. Then betwixt 360 the greatest extreme, and 240 the harmonical mean, take an arithmetical mean, it is 300; and an harmonical mean is 288. Again, betwixt 180, the lesser extreme of the octave, and 270 the first arithmetical mean, it is 225, and an harmonical one 216.

Thus you have a series of all the concords, both ascending towards acuteness from a common fundamental term 360, and descending towards gravity from a common acute term 180: which series has this property, that taking the two extremes, and any other two at equal distances, these four will be geometrically proportional.

The octave, by immediate division, becomes a fourth and fifth; the fifth again, by immediate division, produces the two thirds; the two thirds are therefore found by division, though not immediately. And the same is true of the two sixths. Thus all the original concords arise from the division of the octave; the fifths and fourths immediately, the thirds and sixths mediately.

From the perfection of the octave, it may be doubled, tripled, &c. and yet preserve a concord; that is, the sum of two or more octaves is concord; though the more compound will be gradually less agreeable; but it is not so with any other concord less than octave, the doubles, &c. whereof are all discords.

Again,

Again, whatever found is concord to one extreme of the octave, is concord to the other also; and, if you add any other simple concord to an octave, it agrees to both its extremes, to the nearest being a simple concord, and to the farthest a compound one.

The greatest number of the vibrations of the fundamental, it is to be farther observed, cannot exceed five, or there is no concord where the fundamental makes more than five vibrations to one coincidence with the acute term. This progress of the concords may be carried on *in infinitum*, but the more compound, the less agreeable. A single octave is better than a double one, and that than a triple one; and so of fifths and other concords. Three or four octaves is the greatest length in common practice: the old scales went but to two; no voice or instrument can well reach above four.

CONCORDANCE, a sort of dictionary of the Bible, explaining the words thereof in alphabetical order, with the several books, chapters, and verses quoted, in which they are contained.

CONCORDANT VERSES, are such as have several words in common, but which, by the addition of other words, convey an opposite or at least a very different meaning.

CONCRETE, in the school-philosophy, an assemblage or compound. See the article **COMPOUND**.

CONCRETE, in natural philosophy and chemistry, signifies a body made up of different principles, or any mixed body: thus a soap is the factitious concrete, or a body mixed together by art; and antimony is a natural concrete, or a mixed body, compounded in the bowels of the earth.

CONCRETE, in logic, is used in contradistinction to abstract; for example, when we consider any quality, as whiteness, inherent in a subject, as, suppose, in snow; if we may say the snow is white, then we speak of whiteness in the concrete: but if we consider whiteness by itself, as a quality that may be in paper, in ivory, and in other things, as well as in snow, we are then said to consider, or to take it in the abstract. See the article **ABSTRACT**.

CONCRETE NUMBERS, are those which are applied to express or denote any particular subject, as two men, three pounds, two thirds of a shilling, &c, whereas if nothing be concreted with the number, it is taken abstractly, or universally. Thus three signifies an aggregate of three units; let these units be men, pounds, or whatever else you please.

CONCRETION, the uniting together several small particles of a natural body into sensible masses, or concretes, whereby it becomes so and so figured and determined, and is induced with such and such properties. See **CONCRETE**.

CONCUPISCENCE, according to divines, an irregular appetite, or lust after carnal things, inherent in the nature of man ever since the fall.

CONCURRING, or **CONGRUENT FIGURES**, in geometry, those which being laid upon one another, exactly correspond and cover each other, and therefore are equal.

CONDENSATION, the act whereby a body is rendered more dense, compact, and heavy.

Hence condensation stands opposed to dilatation, or rarefaction; which latter renders the body lighter and looser, by setting the parts further asunder; whereas the former brings them closer to each other, and increases their contact.

Condensation is, by most writers, distinguished from compression, in regard the latter is performed by some external violence; whereas the former is the action of cold.

CONDENSER, a pneumatic engine, or syringe, whereby an uncommon quantity of air may be crowded into a given space; so that sometimes ten atmospheres, or ten times as much air as there is at the same time in the same space, without the engine, may be thrown in by means of it, and its egress prevented by valves properly disposed.

It consists of a brass cylinder wherein is a moveable piston; which being drawn out, the air rushes into the cylinder through a hole provided on purpose; and when the piston is again forced into the cylinder, the air is driven into the receiver through an orifice, furnished with a valve to hinder its getting out.

The receiver or vessel containing the condensed air, should be made very strong, to bear the force of the air's spring thus increased; for which reason they are generally made of brass: its orifice is fitted with a female screw, to receive the male screw at the end of the condenser.

If glass be used for a condenser, it will not suffer so great a degree of condensation; but the experiment will be more entertaining, since the subject may be viewed in the condensed air.

CONDERS, a term used in the herring fishery, for people who stand on cliffs or eminences near the sea coast, to direct the fishermen which way the shoal of herrings passes; their course being more conspicuous to those who stand on high cliffs ashore, than to those on board the vessels.

CONDITION, in the civil law, a clause of obligation stipulated as an article of a treaty or contract.

CONDITION, in common law, a restriction annexed to an act, qualifying or suspending the same, in rendering its effect precarious and uncertain.

CONDITIONAL, something not absolute but subject to conditions.

Conditional legacies are not due till the conditions are accomplished.

The feeds have been recommended by some as demulcent, paretic, and antiprophidiac. Of their real qualities, little more is known with certainty, than that they are innocent to some kinds of birds. Mr. Ray says he found the crop of a thrush full of hemlock seeds, even at the season when corn was plentiful.

Botanists enumerate two or three other species of conium, which are natives of foreign countries.

CONJUGATE DIAMETER, or *Axis of an Ellipsis*, the shortest of the two diameters, or that bisecting the transverse axis. See the article **AXIS**.

CONJUGATE HYPERBOLAS. If there be two opposite hyperbolas *AM, am*, (Plate XXXVII. fig. 1.) whose principal axis is the line *Aa*, and conjugate axis of the line *Bb*; and if there be two other hyperbolas, whose principal axis is the line *Bb*, and conjugate one the line *Aa*; then these four hyperbolas are called conjugate hyperbolas; the two former opposite ones being conjugates to the latter.

CONJUGATION, in grammar, a regular distribution of the several inflexions of verbs in their different voices, moods, tenses, numbers and persons, so as to distinguish them from one another.

The Latins have four conjugations, distinguished by the terminations of the infinitive *äre, äre, äre, äre*; and *ire*; the vowels before *re* of the infinitive in the first, second, and fourth conjugations being long vowels, and that before *re* in the infinitive of the third being a short one. See the article **VOWEL**.

The English have scarce any natural inflexions, deriving all their variations from additional particles, pronouns, &c. whence there is scarce any such thing as strict conjugations in that language.

The French grammarians reduce the number of conjugations in their language to that in the Latin, and these terminating in *er, re, ir, and oir*.

CONJUGATION, in anatomy, is applied to a pair of nerves arising together, and serving the same operation, sensation, and motion.

CONJUNCTION, in astronomy, the meeting of two stars or planets in the same degree of the zodiac.

This conjunction is either true, or apparent. The true conjunction is when a right line, drawn from the eye through the center of one of the bodies, would pass through that of the other: in this case the bodies are in the same degree of longitude and latitude: and here the conjunction is also said to be central, if the same line, continued from the two centers through the eye, do also pass through the center of the earth.

Apparent conjunction is when the two bodies do not meet precisely in the same point, but are joined with some latitude.

In this case a right line, drawn through the center of the two bodies, would not pass through the

center of the earth, but through the eye of the spectator: this conjunction is also called *partile*.

The moon is in conjunction with the sun, when they meet in the same point of the ecliptic, which happens every month; and eclipses of the sun are always occasioned by the conjunction of the sun and moon in or near the nodes of the ecliptic.

In the revolution of Jupiter's satellites, there must be distinguished two conjunctions with the planet; the one made beyond the planet in respect of the sun, and in passing from the western excursion to the eastern, which is called the superior conjunction; the other made on this side the planet, in passing from the eastern excursion to the western, and is called the inferior conjunction. That part of a satellite's orbit, comprehended between the two points of its eastern and western excursions, and where the superior conjunction is made, may be called the superior semi-circle, and the part where the lower conjunction is made the inferior semi-circle. If the planes of the satellites were parallel to the plane of their respective primary planet's orbit, these planes prolonged would pass through the sun; because the plane of each planet's orbit passes through it, consequently all the satellites would appear to move in a right line, in the direction of the planet's diameter, where it is intersected by its orbit; therefore, would never pass above or under the planet's center, when in conjunction with it.

Another consequence of this phenomenon is, supposing the planets and their satellites to have no light but what is reflected from the sun to them; then the satellite passing before the planet's disk, when in their inferior conjunction, must hide the sun from such of the planet's inhabitants who are under their path, and thereby cause an eclipse of the sun to those inhabitants. And, when in their superior conjunction they pass behind the planet's disk, they cease to be enlightened by the sun, and consequently, being sunk in the planet's shade, are not visible while in that shade, or behind the planet's disk, which forms an eclipse of the satellite or moon.

CONJUNCTION, in grammar, an undecidable word, or particle, which serves to join words and sentences together, and thereby shews their relation or dependence one upon another. The conjunction, which is usually placed last in the eight parts of speech, is of great use to render the discourse smooth and fluent, and serves many good purposes in the argumentative or narrative style; but should ever be omitted where a person speaks with emotion, as only serving to weaken and enervate it. Conjunctions are of several kinds.

Adversative CONJUNCTIONS, such as are restrictive, or expressive of contrarieties; as, *but, nevertheless, although*.

Causal

Causal CONJUNCTIONS, such as express the reason of something advanced; as, *for, because, seeing, inasmuch as*.

Conclusive CONJUNCTIONS, such as shew that a consequence is drawn; as, *of consequence, for which reason, but then, so that*.

Conditional CONJUNCTIONS, those that denote a condition; as, *on condition that, if, if not, in case of, provided that*.

Copulative CONJUNCTIONS, such as shew a comparison, or express a relation of union between two things; as, *and, only, as much as, in the same manner as, not only, inasmuch as, but also, neither more nor less*.

Continuative CONJUNCTIONS, such as denote a succession or continuation of the discourse; as, *what-ever it be, even, in effect*.

Disjunctive CONJUNCTIONS, such as import a relation of separation or division; as, *neither, whether, or*.

Dubitative CONJUNCTIONS, such as express some doubt, or suspension of opinion; as, *if, that is to say, &c.*

CONJURATION, magic words, characters, or ceremonies, whereby evil spirits, tempests, &c. are supposed to be raised, or driven away.

CONNARUS, in botany, a genus of plants, whose flower consists of five lanceolated, erect, equal petals; and contains ten subulated erect filaments, topped with roundish antheræ.

The fruit is an oblong, gibbous, bivalvular capsule, of one cell, containing a large ovated seed.

CONNECTICUT, a British colony of North America, bounded by the Massachusetts colony on the north-east; by the sea, on the south; and by New-York, on the west; being about one hundred miles in length, and eighty in breadth.

This colony constitutes a distinct government, of a different form from that of New-England.

CONNECTION, or CONNEXION, the relation whereby one thing adheres to, or depends upon, another. Such is the relation between Euclid's propositions, that the latter cannot subsist but by its connection with the former.

CONNECTION, or CONTINUITY, in the drama, consists in the joining of the several scenes together.

The connection is said to be observed, when the scenes of an act succeed one another immediately, and are so joined, as that the stage is never left empty.

CONNIVENT VALVES, in anatomy, those wrinkles, cellules, and vascules, which are found in the inside of the two great intestines, the ilium and jejunum.

The inner tunic of the guts, being longer than the middle or the outward tunic, does frequently wrinkle, or bag out, in many places, by which

means the passage for the contents become straightened, and the matter through the guts then descends more slowly, so that the lacteals have the more time to imbibe the chyle.

CONNOISSEUR, a French word much used of late in English, to signify a person well versed in any thing: whence it is used for a critic, or a person who is a thorough judge of any subject.

CONOCARPUS, the button-tree, in botany, a plant which grows in all the islands of the West-Indies. It rises with a woody upright stem, about sixteen feet high, sending out many side branches, which also grow erect: these are furnished with spear-shaped leaves, having broad foot-stalks, and are placed alternate on the branches.

The flowers grow upon short branches, which arise from the wings of the leaves. These have three or four small leaves on their lower part under the flowers: each of these branches are terminated by six or eight conical heads of flowers, each coming out of a scaly covering. The flowers are small, of a red colour, having five erect subulated filaments, topped with globose antheræ, with a single style.

The fruit is conical and scaly, and contains a single naked seed.

CONOID, in geometry, is a solid body generated by the revolution of a conic section about its axis.

Elliptical CONOID, is a solid formed by the revolution of an ellipse about one of its diameters, and more generally called a spheroid. See SPHEROID.

Hyperbolic CONOID, is generated by the revolution of an hyperbola ACE (Plate XXXVII. fig. 2.) about its axis AD.

Example I. Let it be required to find the surface of an hyperbolic conoid, generated by the rotation of the hyperbola ACF about its axis AD.

Let E be the center of the hyperbola, and put AE, the semi-transverse diameter, equal to b , and AG, the semi-conjugate diameter, equal to a ; also $BC = x$, and $EB = y$. Now because, from the nature of the curve, $xx = \frac{aa}{bb} \times yy - bb$;

therefore $2xx = \frac{aa}{bb} \times 2yy$; whence $2bbxx = 2aa yy$, and $bbxx = ayy$, and $x = \frac{aay}{bbx}$;

whence $xx = \frac{a^2 y^2}{b^4 x^2}$: substituting this therefore in the general equation, $x = \frac{xx}{x} + \frac{y^2}{x^2}$ in the room

of xx , and we shall have $\frac{a^2 y^2 \cdot b^2}{b^4 \times yy - bb} + \frac{y^2}{x} =$

$\frac{a^2 y^2 \cdot b^2 + b^4 y^2 \cdot x - b^6 y^2 \cdot \frac{1}{x}}{b^4 \times yy - bb} = \frac{a^2 y^2 + b^2 y^4 - b^6}{b^4 \times yy - bb} \times \frac{1}{x} =$

Geometric Diagram

Geometric Diagram

Geometric Diagram

$\times \dot{y} = \frac{\dot{y}}{b} \frac{d^2 y y - b^2}{y y - b b^{\frac{1}{2}}}$, by substituting dd in the room of $aa + bb$, for the fluxion of the curve.

Put $AD = r$, and the circumference generated by the point c , then will the circumference generated by the point C be $= \frac{cx}{r}$ (for as $c : r :: x :$

$\frac{cx}{r}$) $= \frac{c}{r} x$; but from the nature of the curve

$x\dot{x} = \frac{aa}{bb} \times \dot{y}y - bb$; therefore $x = \frac{a}{b} \times \dot{y}y - bb^{\frac{1}{2}}$; whence $\frac{c}{r} x$ will be equal to $\frac{ca}{rb} \times$

$\dot{y}y - bb^{\frac{1}{2}}$, the circumference described by the point C in the terms of the equation of the curve.

This therefore being multiplied $\frac{\dot{y}}{b} \times \frac{d^2 y y - b^2}{y y - b b^{\frac{1}{2}}}$,

the fluxion of the curve line, $A C$, will give $\frac{ca}{rb} \times$

$\frac{d^2 y y - b^2}{y y - b b^{\frac{1}{2}}} \times \frac{\dot{y}}{b} = \frac{cay}{rbb} \times \frac{d^2 y y - b^2}{y y - b b^{\frac{1}{2}}}$,

for the fluxion of the surface generated by the curve line $A C$, about its axis $A B$.

Example II. Let it be required to find the value of the hyperbolic conoid formed by the rotation of the hyperbola $A C F D$, about its axis $A D$.

Having drawn an ordinate, as $B C$, put $D F = r$, $B C = y$, $A B = x$, $A D = a$, and $A E = 2b$, then will $E D = a + 2b$, and $E B = x + 2b$, and the area of the circle generated by the ordinate $B C$ $=$

$\frac{cyy}{2r}$; whence $\frac{cyy\dot{x}}{2r}$ will be the fluxion of the

solid; and because, from the nature of the hyperbola, as $E D \times A D : D F^2 :: E B \times A B : A C^2$;

therefore $aa + 2ab : rr :: xx + 2bx : yy$;

whence $yy = \frac{rrxx + 2brrx}{aa + 2ab}$. Putting there-

fore this last expression in the room of yy , in the fluxion of the solid $\frac{cyy\dot{x}}{2r}$, we shall have

$\frac{crxx\dot{x} + 2bcrx\dot{x}}{2aa + 4ab}$, whose fluent $\frac{crx^2}{6aa + 12ab}$

$+ \frac{bcrxx}{2aa + 4ab} = \frac{crx^2 + 3bcrx^2}{6aa + 12ab}$, for the value of the solid formed by the space $A B C$; whence

$\frac{aa cr + 3 ab cr}{6aa + 12b}$ will be the value of the whole

solid; for when $A B$ flows into, or becomes equal to $A D$, x will become equal to a . Whence it follows,

That the circumscribed cylinder is to the inscribed hyperbolic conoid, as $3a + 6b$ is to $a + 3b$, for the cylinder is $\frac{1}{2}acr$.

Parabolical CONOID is generated by the revolution of a parabola about its axis; and is something

like an half spheroid, only its sides are somewhat straighter.

To find the solid content, multiply the square of the diameter of its base by $.7854$, and multiply that product by half the height, and that last product will be the content required sufficiently accurate for common practice.

To find the content of the lower frustum of a parabolical conoid, multiply the sum of the squares of the lesser and greater diameters by $.3927$, and that product by the height of the frustum, and the last product is the content required.

By fluxions the surface of a parabolic conoid is found in the following manner.

Example I. Let it be required to find the surface of a parabolic conoid, generated by the rotation of the semi-parabola $A D E$, about its axis $A D$, (fig. 3.)

From any point B , let the ordinate $B C$ be drawn parallel to DE ; then put $AB = x$, $BC = y$, $DE = r$, and the circumference of the circle generated by the point $E = c$; whence $\frac{cy}{r}$ will be

the circumference generated by the point C (for as

$r : c :: y : \frac{cy}{r}$); but, from the nature of curve,

$ax = yy$; whence $a\dot{x} = 2y\dot{y}$, and $\dot{x} = \frac{2y\dot{y}}{a}$;

consequently $\dot{x}\dot{x} = \frac{4yy\dot{y}\dot{y}}{aa}$. Substituting this

quantity therefore in the general equation $\dot{z} =$

$\dot{x}\dot{x} + y\dot{y}^{\frac{1}{2}}$ in the room of $\dot{x}\dot{x}$, and we shall have

$\dot{z} = \frac{4yy\dot{y}\dot{y}}{aa^{\frac{1}{2}}} + y\dot{y} = \frac{4yy\dot{y}\dot{y} + aay\dot{y}}{aa^{\frac{1}{2}}}$, which

being multiplied by $\frac{cy}{r}$, the circumference generated

by the point C , will give $\frac{cy}{r} \times \frac{4yy\dot{y}\dot{y} + aay\dot{y}}{aa^{\frac{1}{2}}} =$

$\frac{cy}{r} \times \frac{\dot{y}^{\frac{3}{2}}}{aa^{\frac{1}{2}}} \times 4yy + aa^{\frac{1}{2}} = \frac{cyy\dot{y}}{ar} \times 4yy + aa^{\frac{1}{2}}$

$= \frac{c}{r} \times \frac{y\dot{y}}{a} \times 4yy + aa^{\frac{1}{2}}$, for the fluxion of the

surface generated by the arch $A C$; but the square

root of $4yy + aa$, is $a + \frac{2yy}{a} - \frac{2y^4}{a^3} + \frac{4y^6}{a^5}$

$- \frac{10y^8}{a^7} + \frac{28y^{10}}{a^9}$, &c. This therefore being

multiplied by $\frac{y\dot{y}}{a}$, will give $y\dot{y} + \frac{2y^3\dot{y}}{aa} - \frac{2y^5\dot{y}}{a^3}$

$+ \frac{4y^7\dot{y}}{a^5} - \frac{10y^9\dot{y}}{a^7} + \frac{28y^{11}\dot{y}}{a^9}$, whose fluent $\frac{y^2\dot{y}}{2}$

$+ \frac{y^4}{2aa} - \frac{y^6}{3a^3} + \frac{y^8}{2a^5} - \frac{y^{10}}{a^8} + \frac{7y^{12}}{3a^{10}} \times$

$\frac{c}{r}$, &c. equal (by putting $a = 1$) to $\frac{c}{r} \times \frac{y^2\dot{y}}{2}$

+

$+\frac{y^4}{2}-\frac{y^5}{3}+\frac{y^6}{2}-\frac{y^{10}}{1}+\frac{7y^{12}}{3}$, &c. for the surface generated by the arch AC; but if we suppose $DE = b$, and imagine the ordinate BC to move in the direction AD, till it arrive at, or coincide with the ordinate DE, then y will become equal to b , and we shall have $\frac{c}{r} \times \frac{1}{2} b b + \frac{1}{3} b^4 - \frac{1}{4} b^6 + \frac{1}{5} b^8 - b^{10} + \frac{7}{3} b^{12}$, for the surface of the whole parabolic conoid.

Example II. Let it be required to find the value of a parabolic conoid, generated by the revolution of the semi-parabola ACED (Plate XXXVII. fig. 3.) about its axis AD.

From any point, as B, in the axis AD, let the ordinate BC be drawn parallel to the base DE; then put $AB = x$, $BC = y$, and $DE = r$, also $AD = a$, and the circumference described by the point E = c ; whence to find the circumference generated by the ordinate BC, it will be as r :

$c::y:\frac{cy}{r}$ = to the circumference described by the

point E; whence $\frac{cy}{2r} \times y = \frac{cyy}{2r}$, will be the arch of the same circle. This therefore being multiplied by x , the fluxion of the abscissa, will give $\frac{cyyx}{2r} = \frac{cx^2}{2r}$ (by putting x in the room of yy)

because from the nature of the parabola, $1x = yy$) for the fluxion of the solid generated by the space ABC, whose fluent $\frac{cx^2}{4r} = \frac{cyyx}{4r}$ by putting

yy in the room of x , equal to $\frac{carr}{4r} = \frac{1}{4} acr$ (by

putting a in the room of x , and r in the room of y) will be the value of the solid generated by the whole parabolic space ADE; for if we imagine the ordinate BC in a flowing state, and to move till it arrives at, or coincides with the ordinate DE, then AB will become equal to AD, x will become equal to a , and y will become equal to r . Whence follows,

First, That the parabolic conoid is to the circumfcribing cylinder as 1 to 2; for the cylinder is equal to $\frac{acr}{2}$.

Secondly, That the inscribed cone is to the cylinder as 1 to 3.

Thirdly, That the cylinder, the parabolic conoid, and the cone, are to each other as the numbers 3, $\frac{3}{2}$, 1.

CONOIDES, in anatomy, a gland found in the third ventricle of the brain, called pinealis, from its resemblance to a pine-apple. Descartes fixed the seat of the rational soul in this gland. See the article BRAIN.

CONSANGUINITY, the relation subsisting

between persons of the same blood, or who are sprung from the same root.

CONSCIENCE, in ethics, a secret testimony of the soul, whereby it gives its approbation to things that are naturally good, and condemns those that are evil. When it judges of an action to be performed, it is called in the schools an antecedent conscience; and when it passes sentence on an action which is performed, it is called a subsequent conscience. When the mind is ignorant or uncertain about the motive of an action, or its tendency to good; or when there are several circumstances in the case, some of which being doubtful, render the mind dubious concerning the morality of an action, this is called a doubtful or scrupulous conscience; and if it mistakes concerning these, it is called an erroneous conscience. If the error or ignorance is involuntary or invincible, the action proceeding from that error, or from that ignorance, is reckoned innocent. But if they are the effect of negligence, or of affectation, the conduct flowing from such error is criminal. Not to follow one's conscience, though erroneous and ill-informed, Mr. Hutcheson likewise reckons criminal, as it is the guide of life, and to counteract it shews an incorrigible spirit; yet to follow an erroneous conscience is likewise criminal, if the error which misled the conscience was the effect of inattention, or of any criminal passion.

Some divines maintain that conscience is infallible, and hold it to be that immutable law by which God will judge men. They deny that the understanding can be the source of errors, and lay them all at the door of the will.

CONSCRIBED, a term used by some geometricalians for circumfcribed.

CONSCRIPT, *Conscriptus*, in Roman antiquity, an appellation given to the senators of Rome, who were called conscript-fathers, on account of their names being entered all in one register.

CONSECRATION, the act of devoting any thing to the service and worship of God. The Mosaic law ordained, that all the first-born, both of men and beast, should be sanctified or consecrated to God. We find also, that Joshua consecrated the Gibeonites, as Solomon and David did the Nethinims, to the service of the temple; and that the Hebrews sometimes consecrated their fields and cattle to the Lord, after which they were no longer in their power.

Among the ancient Christians, the consecration of churches was performed with a great deal of pious solemnity. In what manner it was done for the three first ages, is uncertain; the authentic accounts reaching no higher than the fourth, when, in the peaceable reign of Constantine, churches were every where built, and dedicated with great solemnity. Some think the consecration consisted

in setting up the sign of the cross, or in placing a communion-table in the church; and others, that no more was done than preaching a panegyric sermon in commemoration of the founder; and that then they proceeded to prayers, one of which was composed on purpose for the church to be consecrated. The Romanists have a great deal of pious foppery in the ceremonies of consecration; which they bestow on almost every thing, as bells, candles, books, water, oil, spices, palms, swords, banners, pictures, crosses, agnus deis, roses, children's cloths, &c.

In England, churches have been always consecrated with particular ceremonies, the form of which was left to the discretion of the bishop. That observed by bishop Laud, in consecrating St. Catharine Creed church, in London, gave great offence.

CONSECRATION is particularly used for the benediction of the elements in the eucharist.

CONSECTARY, a deduction, or consequence, drawn from a preceding proposition. Some rather choose to call it a consequence, and others a corollary.

CONSENT of Parts, in the animal economy, an agreement or sympathy, whereby when one part is immediately affected, another, at a distance, becomes affected in the same manner.

CONSEQUENCE, in logic, the conclusion, or what results from reason or argument. See CONCLUSION.

The consequence is, that other proposition in which the extremes or premises of a syllogism are joined, or separated; and is gained from what was asserted in the premises.

This word, in a more restrained sense, is used for the relation or connection between two propositions, whereof one is inferred from the other.

CONSEQUENT, something deduced or gathered from a former argumentation. But, in a more precise sense, it is used for the proposition which contains the conclusion, considered in itself, without any regard to the antecedent: in which sense the consequent may be true, though the consequence be false. See the preceding article.

CONSEQUENT of a Ratio, in mathematics, the latter of the two terms of a ratio, or that to which the antecedent is compared; thus in m to n , n is the consequent, and m the antecedent. See the articles RATIO and PROPORTION.

CONSERVATOR, an officer ordained for the security and preservation of the privileges of some cities and communities, having a commission to judge of, and determine the differences among them.

CONSERVATOR of the Peace, in our ancient customs, a person who had a special charge to keep the king's peace.

CONSERVATORY, a term sometimes used for a green-house, or ice-house. See GREEN-HOUSE and ICE-HOUSE.

CONSERVE, in pharmacy, a form of medicine, contrived to preserve the flowers, herbs, roots, or fruits, of several simples, as near as possible to what they are when fresh gathered.

Conserves are made up by beating up the thing to be preserved with sugar, viz. a triple quantity thereof to those that are moist, and a double quantity to those that are least so.

CONSIDERATION, in law, material causes or ground of a contract, without which the party contracting would not be bound.

CONSIGNMENT, in law, the depositing any sum of money, bills, papers, or commodities in good hands; either by appointment of a court of justice, in order to be delivered to the persons to whom they are adjudged; or voluntarily, in order to their being remitted to the persons they belong to, or sent to the places they are designed for.

CONSIGNMENT of Goods, in commerce, is the delivering or making them over to another: thus, goods are said to be consigned to a factor, when they are sent to him to be sold, &c. or when a factor sends back goods to his principal, they are said to be consigned to him.

CONSISTENT Bodies, a term frequently used by Mr. Boyle, to signify such bodies whose parts are firmly united together, so that they do not so easily slide over one another's surfaces as the parts of fluid bodies do.

CONSISTENTS, in church-history, an appellation given to such penitents as were permitted to assist at prayers, but not to partake of the Sacrament.

CONSISTORY, at Rome, is an ecclesiastical assembly held in the presence of the pope, for the reception of princes, or their ambassadors, for the canonization of saints, for the promotion of cardinals, and other important affairs.

CONSISTORIES, among the Jews, were courts of judicature, consisting of twenty-three persons, who were appointed to sit in judgment upon the lives and fortunes of the people, and decide all causes, a few only excepted.

CONSOLATION, a figure in rhetoric, wherein the orator endeavours to moderate the grief of another. A principal regard is always to be had to the circumstances and relations of the parties: thus, a superior may interpose his authority, and even chide: a wise man may dispute, sentences will become him: an inferior is to shew respect and affection, and even that he had this from some wife or learned person: and an equal is to appeal to their common friendship.

CONSOLE, in architecture, an ornament cut upon the key of an arch, which has a projection, and, on occasion, serves to support little corniches, figures, busts, and vases. They are also called mutules and modillions, according to their form. Some

of them are striated, others in form of cartouches, others have drops in form of triglyphs. Those made at the end of a plank of wood, cut triangularwise, are called ancones. See ANCONET.

Mr. Le Clerc is of opinion, that a console should always have something massive to sustain, and serve it as a rest.

CONSONANCE, in music, is ordinarily used in the same sense with concord, viz. for the union or agreement of two sounds produced at the same time, the one grave and the other acute; which mingling in the air in a certain proportion, occasions an accord agreeable to the ear.

Most authors confound consonance and concord together, though some of the more accurate distinguish them, making consonance a mere sounding of two notes together, or in the same time; in contradistinction to the motion of those sounds in succession, or one after the other. In effect, the two notions coincide; for two notes thus played in consonance, constitute concord; and two notes that please the ear in consonance, will please it in succession.

Notes in consonance constitute harmony, as notes in succession constitute melody.

In the popular sense, consonances are either simple or compound. The most perfect is unison; though many authors, both among the ancients and moderns, discard it from the number of consonances, as conceiving consonances an agreeable mixture of grave and acute sounds, and not a repetition of the same sound. The first consonance is the octave, then the fifths, the fourths, the thirds, and sixths: the rest are multiples, or repetitions of these.

CONSONANCE, in grammar, signifies a like cadence of words and periods, a fault to be avoided in English, though the ancients make a figure of them, which they call *ομοιοτελευτον*.

CONSONANT, a letter that cannot be sounded without some single or double vowel before or after it.

Consonants are first divided into single and double; the double are *x* and *z*, the rest are all single, and these are again divided into mutes and liquids; eleven mutes, *b, c, d, f, g, j, k, p, q, t*, and four liquids, *l, m, n, r*. But the most natural division of consonants is that of the Hebrew grammarians, who have been imitated by the grammarians of other oriental languages. These divide the consonants into five classes, with regard to the five principal organs of the voice, which all contribute, it is true, but one more notably than the rest, to certain modifications which make five general kinds of consonants. Each class comprehends several consonants, which result from the different degrees of the same modifications, or from the different motions of the same organs: these organs are the throat, palate, tongue, teeth, lips; whence the five classes of consonants

are denominated guttural, palatal, lingual, dental, and labial.

The abbe Dangeau thinks the nature of the division of the Hebrew grammarians very reasonable, but he does not acquiesce in the distribution they have made of them. In order to find a natural and just division of the consonants, he observes, no regard must be had to the characters that represent them, nor any thing to be considered but their sound, or the modification they give the sound. On this principle the same author finds in the French five labial consonants, *b, p, v, f, m*; five palatal ones, *d, j, g, k, n*; four hisser, *s, z, j, ch*; two liquids, *l* and *r*; two that mix with each other *ll, gn*; and the *b* aspirate.

He adds, 1. That *m* and *n* are properly two nasal consonants, the *m* sounding like a *b* passed thro' the nose, and the *n* like a *d* pronounced through the nose.

2. That among the consonants some are weak, others strong; their difference consisting in this, the former are preceded by a small emission of the voice, that softens them, which the latter have not: the weak are *b, c, d, g, z, j*; the strong are *p, f, k, t, s, ch*: hence we may conclude, that the excess of consonants in one language above another only consists in this, that there are more modifications of sound established in the one than in the other: for all men having the same organs, may form the same modifications; so that it is entirely owing to custom, nothing to nature, that the English have not the *θ* of the Greeks, the *ϑ* and *ϙ* of the Hebrews, the *th* of the Germans, the *gn* of the French, the *gl* of the Italians, and the *ll* of the Welch. Also that the Chinese have no *r*, the Iroquois no labial consonants, the Hurons abundance of aspirates, and the Arabs and Georgians abundance of double consonants. Lastly, to find all the consonants that may be formed in any language, there needs nothing but to observe all the modifications that the sounds of speech will admit of, by which we shall have all the consonants practicable.

CONSONANT *Strings*, in music, are such betwixt whose sounds there is an union or agreement, or the one is an unison to the other. See CONSONANCE and CONCORD.

With regard to consonant strings, Dr. Wallis observes, it hath been long since observed, that if a viol or lute-string be touched with the bow or hand, another string on the same, or another instrument, not far from it, if an unison to it, or an octave, or the like, will at the same time tremble of its own accord; but Dr. Wallis further adds, that not the whole of that other string doth thus tremble, but the several parts severally, according as they are unisons to the whole, or the parts of that string so struck; for instance, supposing A C, (Plate XXXVII. fig. 4.) an upper octave to *a*, and therefore

therefore an unison to each half of it, stopped at β ; now if AC be struck, while $\alpha\gamma$ is open, the two halves of this latter, that is $\alpha\beta$ and $\beta\gamma$ will both tremble, but not the middle point at β ; which will easily be observed, if a little bit of paper be lightly wrapped about the string $\alpha\gamma$, and removed successively from one end of the string to the other: in like manner, if AD, *fig. 5*, be an upper twelfth to $\alpha\delta$, and consequently an unison to its three parts $\alpha\beta$, $\beta\gamma$, and $\gamma\delta$, will severally tremble, but not the points β , γ ; which may be observed in like manner as the former: also, if AE, *fig. 6*, be a double octave to $\alpha\epsilon$, the four quarters of this latter will tremble, when the former is struck, but not the points β , γ , δ : so if AG, *fig. 7*, be a fifth to $\alpha\gamma$, and consequently each half of the former be stopped in D, an unison to each third part of the latter stopped in γ , ϵ , while that former is struck, each part of this latter will tremble severally, but not the points γ , ϵ , and while this latter is struck, each part of the former will tremble, but not the point D: the like will hold in lesser concords, but the less remarkably as the number of divisions encreases. This phenomenon, as far as is known, was first discovered by Mr. William Noble, of Merton college, and after him by Mr. Thomas Pigot of Wadham college, and is now commonly known to musicians: Dr. Wallis adds, that the same string as $\alpha\gamma$, *fig. 4*. being struck in the middle at β , each part being unison to the other, will give no distinct sound at all, but a very confused one; as also if $\alpha\delta$, *fig. 5*, be struck at β or γ , where one part is an octave to the other; and in like manner, if $\alpha\epsilon$, *fig. 6*, be struck at β or δ , the one part being a double octave to the other; and so if $\alpha\zeta$, *fig. 8*, be struck in γ or δ , the one part being a fifth to the other, and thus in other like consonant divisions; but still the less remarkably as the number of divisions increases: this and the former phenomenon Dr. Wallis judges to depend upon one and the same cause, viz. the contemporary vibrations of the several unison parts, which make the one tremble at the motion of the other; but when struck at the respective points of divisions, the sound is incongruous, because the point that should be at rest is disturbed: a lute or viol-string will thus answer, not only to a consonant string on the same, or a neighbouring lute, or viol, but to a consonant note in wind-instruments; which was particularly tried on a viol, answering to the consonant notes on a chamber-organ, but not so remarkably to the wire-strings of an harpsichord: wind-instruments communicate to the air as strong a concussion, if not a stronger, than that of gut-strings; and we feel the waifcot-seats, on which we sit or lean, to tremble constantly at certain notes on the organ or other wind instruments, as well as at the notes of a base-viol: Dr. Wallis was also told, that a thin, fine Venice glass was cracked with the strong

and lasting sound of a trumpet or cornet, sounding near it an unison or a consonant note to that of the tone or ting of the glass, and he thinks it no ways improbable.

Queen CONSORT is said in contradistinction to a sovereign princess, or queen invested with supreme authority. See the article **QUEEN**.

CONSPIRACY, in law, signifies an agreement between two or more, falsely to indict, or procure to be indicted, an innocent person of felony.

CONSPIRATORS are, by statute, defined to be such as bind themselves by oath, covenant, or other alliance, to assist one another, falsely and maliciously to indict persons, or falsely to maintain pleas. Likewise those that retain men in the countries with liveries or fees, in order to support their malicious enterprizes, which extends as well to the takers as the givers, and to stewards and bailiffs of lords, who, by their office or power, take upon them to maintain quarrels.

Conspirators in treason are those that plot against the king and government.

CONSPIRING POWERS, in mechanics, those acting in directions not opposite. See the article **POWER**.

CONSTABLE. Lord high constable, an ancient officer of the crowns, both of England and France, whose authority was so very extensive, that the office has been laid aside in both kingdoms, except on particular occasions, such as the king's coronation. The constable of France had his person privileged, and, during the king's minority, was named next to the princes of the blood. The army obeyed him next the king: he managed all that belonged to war, either for punishment of delinquents, distribution of booty, surrender of places, &c. The jurisdiction and functions of this office are now in the marshals of France.

The function of the constable of England consisted in the care of the common peace of the land, in deeds of arms and matters of war. By a law of Richard II. the constable of England has the determination of things concerning wars and blazonry of arms, which cannot be discussed by the common law. The first constable was created by the Conqueror: the office continued hereditary till the thirteenth of Henry VIII. when it was laid aside, as being so powerful as to become troublesome to the king. We have also constables denominated from particular places, as constables of the Tower, of Dover-castle, of Windsor-castle, of the castle of Caernarvon, and many other of the castles of Wales, whose office is the same with that of the castellan, or governors of castles.

From the lord-high constable are derived those inferior ones, since called the constables of hundreds or franchises, who were first ordained in the thirteenth of Edward I. by the statute of Winchester, which, for the conservation of peace and view of

armour,

armour, appointed that two constables should be chosen in every hundred. These are what we now call high-constables, on account that the increase of people and offences has made it necessary to appoint others under these, in every town, called petty-constables, who are of the like nature, though of inferior authority to the other. The high-constable over the whole hundred is usually chosen and sworn into his office by the justices of the peace, in their sessions; and as to petty-constables in towns, villages, &c. the right of choosing them belongs to the court-leet, though they may be elected by the parishioners. They are appointed yearly, and ought to be men of honesty, knowledge, and ability; and if they refuse to serve, or do not perform their duty, they may be bound over to the sessions, and there indicted and fined.

CONSTAT, in law, a certificate that the clerk of the pipe and auditors of the exchequer grant at the request of any person who intends to plead or move in that court for the discharge of any thing. A constat is superior to an ordinary certificate, because it contains nothing but what is evident on record.

CONSTELLATION, in astronomy, is a system of several stars that are seen in the heavens near to one another.

The astronomer to avoid confusion, and to be able to point out any one star, without being allowed to give a particular name to each, divides them into separate parcels, of which he will make a particular plan; and to each of these parcels he will assign a figure at pleasure, such as a ram, a bull, a dragon, &c. so that all the stars in each of the parcels drawn on the plan, may be inclosed in the designed figures, and correspond to the different parts from whence they take their name.

For example. Having drawn a bull about a parcel of stars, that star which falls in the eye is called the star in the Bull's Eye; another which respects the tip of the horn, will be named the Bull's Horn. By this means, if any new phenomenon is seen in the heavens among the stars thus divided into parcels, it is directly known in what part of the heavens it is in, as in the horn, or towards the bull's head, &c.

A parcel of stars thus contained in an assigned figure is called a constellation. But we would advise our young astronomers, or such who are making themselves acquainted with the names of the stars, not to expect that they shall find any parcel of stars forming the figure from which they take their names, or have any likeness in many of these constellations, or rather in none but the triangles.

In practical geometry, when an exact plan of a piece of ground is to be drawn, the figure may be divided from each three objects into triangles, whose sides are measured by an instrument, such as a

chain, and the triangles are joined together by the common sides: in the same manner, the observer will imagine that each star forms with any other two, a spheric triangle, whose sides are arcs, on the concave sphere, comprehended between the stars; and since the centre of these arcs are at his eye, he can measure them by the arc of an instrument of a circular form; whose radius is sufficiently large, to distinguish degrees, minutes, and seconds.

Now having determined the arcs shewing the distances of each star from two or three others, they may be put on a globe, on which may be drawn the figures of the constellations; or general and particular charts may be made of them, in the same manner, as on the terrestrial globe all the points on the surface of the earth are drawn, whose reciprocal distances are known; or as the geographical charts are made.

As the earth intercepts from its inhabitants a part of the fixed stars, so the ancient astronomers divided that part of the heavens which they knew, into forty-eight principal constellations, viz. the Great Bear, Little Bear, Dragon, Cepheus, Cassiopeia, Andromeda, Perseus, Bootes, Northern Crown, Hercules, Harp, Swan, Serpentarius, Serpens, Vulpeculae and Anseris, Sagitta, Eagle and Antinous, Dolphin, Little Horse, Pegasus, Northern Triangle, Aries, Taurus, Gemini, Cancer, Leo, Virgo, Libra, Scorpio, Sagittarius, Capricorn, Aquarius, Pisces, Whale, Orion, Eridanus, Hare, Great Dog, Little Dog, Ship Argo, Hydra, Cup, Crow, Centaur, Wolf, Altar, Southern Crown, and Southern Fish.

Within the last three hundred years, navigators who had sailed to countries unknown to the ancients, having discovered those stars which are never seen in Europe, have formed them into twelve new constellations, viz. the Peacock, Crane, Toucan, Phenix, Gold Fish, Flying Fish, Hydrus, Camelion, Bee, Indian Bird, Southern Triangle, Indian, the Greyhounds, Lacenta, Monceros, &c.

The figures attributed to these new constellations had no other origin than the fancy of those who named them. It is not so with those of the ancients, which took their origin from the religious ceremonies of the Ethiopians, Egyptians, Phenicians and Caldeans. The Greeks adopted a part, and disguised the rest by substituting names and figures drawn from their fabulous history; this has been the subject of several learned dissertations, which may be consulted.

The venerable Bede, indeed, out of a vain zeal, instead of the names and figures of the twelve constellations, substituted those of the twelve apostles; Julius Schillerius, in 1627, completed the reformation, and gave scripture-names to all the constellations in the heavens. But as these innovations could serve no purpose, but that of introducing quarrels
into

into astronomy, the old constellations are still retained, both because better could not be substituted, and likewise to keep up the greater correspondence and uniformity between the old astronomy and the new.

The division of the stars by images and figures is of great antiquity, and seems to be as old as astronomy itself; for in the most ancient book of Job, Orion, Arcturus, and the Pleiades are mentioned; and we meet with the names of many of the constellations in the writings of the first poets Homer and Hesiod.

The history of each constellation, with the number of stars each contains, see under their respective names, likewise see CATALOGUE, ASTRONOMY, &c.

CONSTIPATION, in medicine, a hardness of the belly, with great costiveness.

CONSTITUENT PART, in physiology, an essential part in the composition of any thing, differing little from what is otherwise called element or principle.

CONSTITUTION, in matters of policy, signifies the form of government established in any country or kingdom.

CONSTITUTION, in a physical sense, is that particular disposition of the human body, which results from the properties and mutual actions of the solids and fluids, and which renders them capable of exercising the functions proper and conformable to nature.

CONSTRUCTOR, an appellation given to several muscles, on account of their confining or closing some of the orifices of the body. Thus,

CONSTRUCTOR LABIORUM, called also orbicularis, because its fibres are of an arched figure, is a muscle which constitutes the very substance of the lips, and draws them up, as in kissing; whence it is also called basiator and osculatorius.

CONSTRUCTOR NASI, a muscle arising above the dentes incisores of the upper jaw, and terminating in the alæ of the nose. It is but single, though Santorini will have it that it is double, and is not particular in human subjects, as in many of the quadrupeds. Properly speaking, indeed, there is in the human frame no such muscle as the constructor orbicularis of beasts, but this serves in some degree in its office. The use is to draw the alæ downwards, and at the same time to draw the upper lip downwards, in which action it is very much assisted by the constrictor of the lips.

CONSTRUCTION, in geometry, is drawing such lines as are previously necessary for the making any demonstration appear more plain and undeniably.

CONSTRUCTION of Equations, in algebra, is finding the unknown quantities, or the roots of an equation, either by straight lines or curves; or it is the

method of drawing a geometrical figure, whose properties shall express the given equation, in order to demonstrate the truth of it.

CONSTRUCTION of simple Equations is affected by revolving the fractions to which the unknown quantity is equal into proportional parts. Thus, if

$\frac{ca}{b} = z$, then it will be as $b : c :: a : z$; whence z will be determined by finding a fourth proportional.

Suppose the equation $\frac{ab + mn}{r - s} = z$. The first

thing to be done is to find a mean proportional between a and b , which suppose to be p ; also another between m and n , which call q , then the equation will stand thus, $\frac{pq + pq}{r - s} = z$: which may be

constructed thus. Let the base AB, (Plate XXXVII. fig. 9.) of the right angled triangles APB, be made equal to g , and the perpendicular AP equal to p ; then will PB^2 be equal $qq + pp$; which, according to the equation is to be divided by $r - s$; therefore it will be as $r - s : PB (= \sqrt{qq + pp}) :: PB$ to a third proportionable, which will give z .

CONSTRUCTION of quadratic Equations. In order to render this sort of construction more easy to the young geometer, we advise that he would consider well the nature of the second order of curves which are made use of in constructing quadratic equations, and which he will find under the article curve; and then peruse the following method, which is given by the ingenious Mr. Maclaurin in the latter part of his algebra.

The general equation expressing the nature of the lines of the second order, having all its terms and coefficients, will be of this form;

$$\left. \begin{array}{l} y^2 + axy + cx^2 \\ + by + dx \\ + e \end{array} \right\} = 0$$

where a, b, c, d, e , represent any given quantities with their proper signs prefixed to them.

If a quadratic equation is given, as $y^2 + py + q = 0$, and, by comparing it with the preceding, if you take the quantities a, b, c, d, e , and x such that $ax + b = p$, and $cx^2 + dx + e = q$, then will the values of y in the first equation be equal to the values of it in the second; and if the locus be described belonging to the first equation, the two values of the ordinate when $ax + b = p$ and $cx^2 + dx + e = q$, will be the two roots of the equation $y^2 + py + q = 0$.

And as four of the given quantities a, b, c, d, e , may be taken at pleasure, and the fifth, with the abscissa x , determined, so that $ax + b$ may be still equal to p , and $cx^2 + dx + e = q$; hence there are innumerable ways of constructing the same equation.

always four affirmative roots on the right side of the axis, which the latter has sometimes on the right and sometimes on the left.

As to cubic equations, they are to be reduced to biquadratics, before they can be constructed by the same general rule; which is done by multiplying the equation proposed by its root z , whence arises a biquadratic equation, in which the last term or r is wanting; wherefore taking away the second term, and finding the centre E , the line EO is the radius of the circle; viz. when $ar = 0$; and the whole fifth term, in the new equation, arises from the taking away of the second term.

Example II. $z^3 - bzx + apz + aag = 0$, which, multiplied into z , becomes $z^4 - bzzx + apz^2 + aazq = 0$; to take away the second term, let $x + \frac{1}{2}b = z$ and it will be,

$$\begin{aligned} x^4 + bx^3 + \frac{3}{2}bbxx + \frac{1}{2}b^3x + \frac{3}{2}abx + \frac{1}{2}ab^2 \\ - bx^3 - \frac{1}{2}bbxx + \frac{1}{2}b^3x - \frac{3}{2}abx - \frac{1}{2}ab^2 \\ + apxx + \frac{1}{2}apbx + \frac{1}{2}apbb = + apxx \\ + aagx + \frac{1}{2}aagb = + aagx. \end{aligned}$$

In this new equation, the half coefficient of the third term divided by a , viz. $\frac{\frac{3}{2}bb}{16aa} + \frac{1}{2}p$ is to be substituted for $\frac{1}{2}p$; and the half coefficient of the fourth term divided by a , the square of the latus rectum, viz. $\frac{b^2}{16aa} + \frac{pb}{4a} + \frac{1}{2}q$ is instead of $\frac{1}{2}q$ in Cartes's construction, from whence the centre E is determined; then drawing a parallel to the axis, at the distance $\frac{1}{2}b$ to the left side, because $x + \frac{1}{2}b = z$, whose intersection with the parabola, let be O ; a circle described from the centre E and with the radius EO will either cut or touch the parabola, in as many points as the equation hath true roots; which roots, or z are perpendiculars let fall from those points upon the parallel to the axis, the affirmative on the right side, and the negative on the left: if the third or fourth term, or both, be wanting in the equation, in investigating the central rule, there is no manner of difference at all to be observed; but the quantity p or q being wanting, those parts of the lines CD and DE , in some measure deduced from that quantity, will be wanting too; and we are to proceed with the remaining coefficients of the third and fourth terms in the new equation, according to the method prescribed in the preceding examples.

CONSTRUCTION, in grammar, the connecting the words of a sentence according to the rules of the language.

CONSUBSTANTIAL, among divines, a term denoting something of the same substance with another. Thus the orthodox believe the Son of God to be consubstantial with the Father.

CONSUBSTANTIATION, a tenet of the Romish and Lutheran churches with regard to the manner of the change made in the bread and wine in the eucharist.

CONSUL, the chief magistrate of the Roman commonwealth. They were two in number, chosen every year in the campus martius, by the people assembled in the comitia centuriata.

CONSUL, at present, is an officer established by virtue of a commission from the king and other princes, in all foreign countries of any considerable trade to facilitate and dispatch business, and protect the merchants of that nation.

CONSULATION, in law, a writ by which a cause being removed from the spiritual court to the king's court, is returned thither again; and the reason is, that if the judges of the king's court, by comparing the libel with the suggestion of the party, find the suggestion false or not proved, and on that account the cause to be wrongfully called from the ecclesiastical court, then upon this consultation or deliberation; they decree it to be returned.

CONSUMPTION, in medicine. See the article **PATHISIS**.

CONTACT, is when one line, plane, or body, is made to touch another; and the parts that thus touch, are called the points or places of contact. The contact of two spherical bodies, and of a tangent with the circumference of a circle, is only in one point.

CONTACTION, in physics, the communicating a disease from one body to another, either by contact or morbid effluvia.

CONTARA, a name used by some botanists for the plant that produces the ignatius's beans, used in medicine.

CONTEMPLATION, an act of the mind, whereby it applies itself to consider and reflect upon the works of God, nature, &c.

CONTEMPORARY, a person or thing that existed in the same age with another. Thus Socrates, Plato, and Aristophanes, were contemporaries.

CONTENEMENT, in our old law books, a term of different import; being sometimes used for credit, or countenance; and, at other times, for the maintenance proper for each person, according to his rank and condition in the commonwealth.

CONTENT, in geometry, the area or quantity of matter or space included in certain bounds.

For the contents of vessels of different kinds, see the article **GAUGING**.

CONTENTIOUS JURISDICTION, in law, denotes a court which has power to decide differences between contending parties.

CONTEXT, among divines and critics, that part of scripture or of a writing that precedes and follows the text. See the article **TEXT**.

CONTIGNATION, in the ancient architecture, the art of laying rafters together, and particularly flooring.

CONTIGUITY, in geometry, is when the surface of one body touches that of another.

CONTIGUOUS ANGLES, in geometry, are such as have one leg common to each angle, and are sometimes called adjoining angles, in contradistinction to those produced by continuing their legs through the point of contact, which are called opposite or vertical angles. See **ANGLE**.

CONTINENT, in general, an appellation given to things continued without interruption; in which sense we say, continent fever, &c. See the article **FEVER**.

CONTINENT, in geography, is what is frequently called the main land, and comprehends several countries, kingdoms, and states, not separate from each other; being only four, viz. Europe, Asia, Africa, and America.

To the north of Europe is contained Russia, Sweden, Norway, Denmark, and France. In the middle, Germany and Poland; and to the south, Spain, Italy, and Turkey in Europe.

To the north of Asia is comprehended the vast continent of Tartary; and to the south, China, India, Persia, and Turkey in Asia.

In Africa, is contained Egypt, Barbary, Biledulgerid, Zura or the Desert, Negroland, Guiney, Nubia, and Ethiopia Interior and Exterior.

To the north of America we have Mexico, Granada, Florida, Terra Canadensis, Terra Arctica; and to the south, Terra Firma, Peru, the land of the Amazons, Brasil, Chili, Paraguay, Patagonia, and Terra Antarctica.

CONTINENT Cause of a Distemper, that upon which the disease depends so immediately, that it continues so long as that remains, and no longer.

CONTINENT FEVER, that which proceeds to a crisis, without either intermission or remission. See the article **SYNOCHUS**.

CONTINGENT, something casual or uncertain. Hence future contingent, in logic, denotes a conditional event which may or may not happen, according as circumstances fall out. The Socinians maintain, that God cannot foresee future contingents, because depending on the free motions of the will of man.

CONTINGENT is also a term of relation for the quota that falls to any person upon a division. Thus each prince in Germany, in time of war, is to furnish for many men, so much money and ammunition for his contingent.

CONTINGENT USE, in law, is an use limited in a conveyance of lands which may or may not happen to vest, according to the contingency mentioned in the limitation of the use. And a contingent remainder is when an estate is limited to take place at a time to come, on an uncertain event.

CONTINGENT LINE, in dialling, is a line that crosses the substyle at right angles. See **SUBSTYLE** and **DIALLING**.

CONTINGENTS are sometimes used by mathema-

ticians in the same sense as tangents. See the article **TANGENT**.

CONTINUAL CLAIM, in law, a claim that is made from time to time within every year and a day to lands, &c. which in some respect one cannot attain without danger.

CONTINUAL PROPORTION. See the article **PROPORTION**.

CONTINUANTO, a term used in a special declaration of trespass, where the plaintiff would recover damages for several trespasses in one and the same action.

CONTINUATO, in music, signifies, especially in vocal music, to continue or hold on a sound in an equal strength or manner, or to continue a movement in an equal degree of time all the way.

CONTINUED PROPORTION, in arithmetic, is that where the consequent of the first ratio is the same with the antecedent of the second; as 4 : 8 : 8 : 16, in contradistinction to discrete proportion. See the article **DISCRETE**.

CONTINUED Thorough Bass, in music, that which continues to play constantly, both during the recitatives and to sustain the chorus. See the article **CHORUS**.

CONTINUO, in music, signifies the thorough bass, as basso continuo, is the continual or thorough bass.

CONTINUOUS FEVERS, those otherwise called continent. See **CONTINENT**.

CONTOBADDITES, in church history, a sect of heretics in the sixth century, who allowed of no bishops.

CONTOUR, in painting, the out-line, or that which defines a figure.

A great part of the skill of the painter lies in managing the contours well. Contour, with the Italian painters, signifies the lineaments of the face.

CONTOURNE, in heraldry, is used when a beast is represented standing or running with its face to the sinister side of the escutcheon, they being always supposed to look to the right, if not otherwise expressed.

CONTOURNIATED, a term among antiquaries applied to medals, the edges of which appear as if turned in a lathe.

CONTRABAND, in commerce, a prohibited commodity or merchandize bought or sold, imported or exported, in prejudice to the laws and ordinances of a state, or the public prohibitions of the sovereign.

Contraband goods are not only liable to confiscation themselves, but also subject all other allowed merchandise found in the same box, bale, or parcel, together with the horses, waggons, &c. which conduct them. There are contrabands likewise, which besides the forfeiture of the goods,

are attended with several penalties and disabilities.

CONTRACT, in a general sense, a mutual promise of two or more parties, who voluntarily promise and oblige themselves to do something, pay a certain sum, or the like. All donations, exchanges, leases, &c. are so many different contracts.

CONTRACT, in common law, an agreement or bargain between two or more persons with a legal consideration or cause; as where a person sells goods, &c. to another for a sum of money; or covenants, in consideration of a certain sum, or an annual rent, to grant a lease of a messuage, &c.

CONTRACT is also used for the instrument in writing which serves as a proof of the consent granted, and the obligation passed between the parties.

CONTRATILE FORCE, that property or power inherent in certain bodies, whereby, when extended, they are enabled to draw themselves up again to their former dimensions.

CONTRACTION, in grammar, is the reducing of two syllables into one, as *can't* for *cannot*, *should'st* for *should'st*, &c.

CONTRACTION, in logic, a sort of reduction, whereby things are abridged, or brought into less compass.

CONTRACTION, in physics, the diminishing the extent or dimensions of a body, or the causing its parts to approach nearer to each other, in which sense it stands opposed to dilatation or expansion.

CONTRADICTION, a sort of direct opposition, wherein one thing is found directly contrary to another.

CONTRADICTORY PROPOSITIONS, in logic, are such as differ both in quality and quantity, one being universal, and the other particular, which constitutes the opposition of quantity; one affirmative and the other negative, which makes the opposition in quality: thus, *A. Every vine is a tree. O. Some vine is not a tree.* These can never be both true, and both false at the same time. To this it is necessary that the one deny, and the other affirm, the same thing of the same subject, considered in the same circumstances, every thing having always its own essence. This logicians express by *affirmare, & negare idem, de eodem secundum idem.* If two universals differ in quality, they are contradictory; as, *A. Every vine is a tree. E. No vine is a tree.* Those can never be both true together, but they may be both false. If two particular propositions differ in quality only, they are subcontradictory; as, *J. Some vine is a tree. O. Some vine is not a tree.* These may be both true together, but they can never be both false. There are likewise contradictory propositions on an individual, which are called single contradictories; as, *Peter is just, Peter is not just.* Now in such as these, Peter must

be considered at the same time, without which they may be both true; since there was a time wherein Peter was just, and wherein he was not.

Seeming contradictories is when the members of a period quite disagree in appearance and sound, but perfectly agree and are consistent in sense: thus,

“Cowards die many times before their death;

“The valiant never taste of death but once.”

SHAKESPEAR.

CONTRA-FISSURE, in surgery, a kind of fracture, or fissure, in the cranium, which sometimes happens on the side opposite to that which received the blow; or, at least, at some distance from it.

CONTRA-HARMONICAL PROPORTION, in arithmetic, is that relation of three terms, wherein the difference of the first and second is to the difference of the second and third, as the third is to the first: thus, 3, 5, and 6, are numbers contra-harmonically proportional, for 2 : 1 :: 6 : 3.

CONTRA-INDICATION, in medicine, an indication which forbids that to be done, which the main scope of a disease points out: as if, in the cure of a disease, a vomit was judged proper; if the patient be subject to a vomiting of blood, it is a sufficient contra-indication as to its exhibition. See **INDICATION**.

CONTRALTO, in music, a term used by the Italians for two haut contres, because they play contrary to each other. See the article **HAUT CONTRÉ**.

CONTRAMURE, in fortification, is a wall built before another partition-wall, to strengthen it, so that it may receive no damage from the adjacent buildings. See **WALL** and **RAMPART**.

CONTRAST, in painting and sculpture, expresses an opposition or difference of position, attitude, &c. of two or more figures, contrived to make variety in a painting, &c. as where, in a groupe of three figures, one is shewn before, another behind, and another sideways, they are said to be in contrast.

The contrast is not only to be observed in the position of several figures, but also in that of the several members of the same figure: thus, if the right arm advance farthest, the right leg is to be hindermost; if the eye be directed one way, the arm to go the contrary way, &c. the contrast must be pursued even in the drapery.

CONTRAST, in architecture, is to avoid the repetition of the same thing, in order to please by variety.

CONTRATE-WHEEL, in watch-work, that next to the crown, the teeth and hoop whereof lie contrary to those of the other wheels, from whence it takes its name. See the article **WATCH**.

CONTRAVALLATION, in the military art, a line formed in the same manner as the line of circum-

circumvallation, to defend the besiegers, or the army which forms the siege, against the enterprizes of the garrison.

The trench of the circumvallation is towards the field, at the foot of the parapet; and that of the contravallation towards the town, and also at the foot of the parapet. The line of contravallation is never made but when the garrison is numerous enough to harraß and interrupt the besiegers by sallies.

This line is constructed in the rear of the camp, and by the same rule as the line of circumvallation, with this difference, that as it is only intended to resist a body of troops much inferior to a force which might attack the circumvallation, so its parapet is not made so thick, nor the fosse so wide and deep. Its parapet need not be more than six feet thick, and the ditch eight feet at the brink, and five feet deep: the redans of this line are constructed in the same manner as in the circumvallation. All that concerns this line, may be sufficiently known by an examination of the figure of it in Plate XXXVIII. which exhibits a part of this, and part of the circumvallation, with the camp in the interval.

Amongst the antients this line was very common, but their garrisons were much stronger than ours; for as the inhabitants of towns were then almost the only soldiers, there were commonly as many troops to defend a place as there were inhabitants in it.

The lines of circumvallation and contravallation are very ancient, examples of them being found in histories of the remotest antiquity. The author of the Military History of Louis le Grand, pretends, however, that Cæsar was the first inventor of them; but it appears from the Chevalier de Folard's Treatise on the Method of Attacks and Defences of Places, used by the Antients, how little foundation there is for this opinion. This author asserts, with great probability on his side, that these lines are as antient as the time in which towns were first surrounded with walls, or in other words, fortified.

CONTRAYERVA, in the materia medica, the name which the roots of the dorfenia is known by in the shops. See the article DORSTENIA.

The root is an inch or two in length, and about half an inch thick; full of knots and irregular tubercles; surrounded on all sides with numerous long tough fibres, most of which are loaded with scaly knobs; of a reddish brown colour on the outside, and pale within. It was first brought into Europe, about the year 1581, by Sir Francis Drake.

This root, freed from the fibres, which are much weaker than the tuberos part, has a light aromatic smell, and a roughish, bitterish, penetrating taste, which, as Teller observes, is not easily concealed by a large admixture of other substances. It is given, as a diaphoretic and antiseptic, in low and malignant fevers, and appears to be one of the

mildest and safest of the substances of the pungent kind commonly made use of in these intentions, not being liable to produce, though taken pretty freely, any considerable heat. The dose, in substance, is from five or six grains to half a dram and more; in decoction or infusion, from half a dram to two drams.

CONTRE, in heraldry, an appellation given to several bearings, on account of their cutting the shield contrary and opposite ways: thus we meet with contre-bend, contre-chevron, contre-pale, &c. when there are two ordinaries of the same nature opposite to each other, so as colour may be opposed to metal, and metal to colour.

CONTRIBUTION, in a general sense, the payment of each person's quota, or the share he bears in some imposition or common expence. Contributions are either voluntary, as those of expences for carrying on some undertaking for the public interest; or involuntary, as those of taxes and imposts.

CONTRIBUTION, in a military sense, an imposition or tax paid by frontier-countriers to an enemy, to prevent their being plundered and ruined by him.

CONTRITION, in theology, a sorrow for our sins, resulting from the reflection of having offended God, from the sole consideration of his goodness, without any regard to the punishment due to the trespass, and attended with a sincere resolution of reforming them.

CONTROL, COMPTROL, or CONTROLE, is properly a double register kept of acts, issues of the officers or commissioners in the revenues, army, &c. in order to perceive the true state thereof, and to certify the truth, and the due keeping of the acts subject to the enregistrement.

CONTROLLER, an officer appointed to control or oversee the accounts of other officers, and, on occasions, to certify whether or no things have been controlled or examined.

CONTROLLER of the Navy, one of the principal officers of the navy-board, at which he presides to superintend and control the inferior and civil department of the marine, as the admiralty directs the superior and military operations of it.

CONTROVER, in law, a person who, of his own head, invents and spreads false news.

CONTUMACY, in law, a refusal to appear in court, when legally summoned; or the disobedience to the rules and orders of a court having power to punish such offence.

CONTUSION, in medicine, a bruise, or a solution of continuity, produced in any part of the body by any instrument whose surface does not rise by way of edge, but in any obtuse figure; by this means a contusion is distinguished from a wound, which is a solution of continuity produced by a sharp cutting instrument.

CONVALLARIA, lily of the valley, in botany, a genus of plants, whose flower is monopetalous and campanulated, divided at the top into six obtuse parts, which spread open and are reflexed; it hath six subulated filaments inserted in the petal, which are topped with oblong erect antheræ. The fruit is a globose berry with three cells, containing a roundish seed.

The common lily of the valley hath a slender, white fibrous root, creeping near the top of the ground. The leaves come out by pairs, of a shining light green, oblong, acuminate, and nervous; the foot-stalks of the flowers arise immediately from the root on one side of the leaves; these are naked, about five inches long, and are furnished toward their top with pendulous white flowers, of an odoriferous scent. This plant is perennial, grows wild in woods and shady places, flowers in May, and the seeds are ripe in autumn. The flowers are used in medicine; they have a bitterish taste, and when dried, powdered, and snuffed up the nose, prove a strong sternutatory; they are esteemed cephalic and cordial, and therefore recommended in palsies, epilepsies, and spasms. Of these flowers was formerly prepared a distilled water, a conserve, and an oil, but they are all now much in disuse. To this genus Linnæus has added the polygonatum and unifolium of other authors.

CONVENTICLE, a private assembly or meeting for the exercise of religion.

CONVENTION, a treaty, contract, or agreement between two or more parties. Every convention among men, provided it be not contrary to honesty and good manners, produces a natural obligation, and makes the performance a point of conscience.

CONVENTION is also a name given to an extraordinary assembly of parliament, or the states of the realm, held without the king's writ.

CONVENTUAL, in general, denotes something belonging to a convent or monastery.

CONVERGING, or **CONVERGENT LINES**, in geometry, are such as continually approach nearer one another; or whose distance becomes still less and less. These are opposed to divergent lines, the distance of which become continually greater: those lines which converge one way, diverge the other.

CONVERGING HYPERBOLA, is one whose concave legs bend in towards one another, and run both the same way. See **HYPERBOLA** and **CURVE**.

CONVERGING RAYS, are such as, proceeding from a body, approach nearer and nearer together in their progress, tending to one certain point, where they all unite: thus the rays proceeding from the object AB (Plate XXXVII. fig. 9.) to the point F, F, are said to converge towards that point.

CONVERSE, in mathematics. One proposition is called the converse of another, when, after a conclusion is drawn from something supposed in the

converse proposition, that conclusion is supposed; and then, that which in the other was supposed, is now drawn as a conclusion from it: thus, when two sides of a triangle are equal, the angles under these sides are equal; and on the converse, if these angles are equal, the two sides are equal. See **TRIANGLE**.

CONVERSION, in a moral sense, implies a repentance of temper and conduct unworthy our nature, and unbecoming our obligations to its author, and a resolution to act a wiser and a better part for the future.

CONVERSION, in rhetoric, &c. is understood of arguments, which are returned, retorted, and shewn on opposite sides, by changing the subject into the attribute, and the attribute into the subject. See **ATTRIBUTE**, &c.

CONVERSION, in war, a military motion whereby the front of a battalion is turned where the flank was, in case the battalion is attacked in the flank. See the article **QUARTER-WHEELING**.

CONVERSION of Equations, in algebra, is when the quantities sought, or any part or degree thereof being fractions, the whole is reduced to one common denominator which may be omitted. Thus, suppose $a + b = \frac{x - z}{a}$, then multiplying all the

numerators in the equation by a excepting its own, it will stand thus $aa + ba = x - z$ therefore conversion of equations is nothing more than what is commonly termed clearing an equation from fractions, which is done by multiplying each numerator in the equator by the fraction's denominator, only omitting the fraction's own denominator. See **EQUATION**.

CONVEX, an appellation given to the exterior part or surface of any thing that is globular or gibbous, in opposition to the hollow or inner surface of such bodies, which is called concave; thus we say a convex frieze, lens, mirror, &c.

CONVEX LENS is a glass that has one of its superficies convex, and the other plane, which is called Plano-convex. Or it has both sides spherical, and then is called a double convex lens.

As perspectives of one convex-glass make objects appear upright, which those of two convex-glasses invert, and again those of three rectify, so it should seem that those of four should invert; and yet experience shews that objects appear upright through these glasses.

According to Mr. Molyneux, this phenomenon appears easily explicable from the consideration of placing glasses in a tube; which is thus, after the object-glass, the eye-glass is placed so much distant, towards the eye, from the focus of the object-glass, as is the focus of the eye-glass; then the middle eye-glass is placed at such a distance from the focus of the first eye-glass, as is the focus of this middle eye-glass; lastly, the nearest eye-glass is placed

placed so much distant from the focus of this middle eye-glass, as is the focus of this nearest eye-glass; and the eye, looking through them all, is placed in the focus of this nearest eye-glass: therefore, in the first place, one single convex-glass cannot properly be said by itself to shew objects erect or reversed, but in respect of placing the eye, that looks through it; for if the eye be placed nearer to it, than the focus of the glass, the objects are erect; if the eye be placed just in the focus, the objects are neither erect nor reversed, but all in confusion, and between both; and if the eye be placed farther from the glass than the focus, the objects are reversed; and here by distant objects are meant, the rays, flowing from any point of which, may be counted to come parallel towards the object-glass: secondly, the object-glass of a telescope reverses the object, both to the eye-glass and to the eye, that looks through it; for the eye-glass is placed farther from the object-glass than is the focus of the object-glass; but the eye-glass contributes nothing towards the rectification or reversion, the eye being placed just in its focus: thus we see, that the reverling of objects in a telescope of two convex-glasses proceeds wholly from the object-glass and its position; and the eye-glass contributes nothing thereto; for were the eye itself in the place of the eye glass, it would see the objects inverted through the single object-glass. To come now to the second eye-glass placed after the first, which is that next the object-glass, it is manifest that if we place our eye nearer to this middle eye-glass than its focus, the eye sees the objects inverted and confused; place the eye in the focus, the objects appear all in confusion, and neither erect nor reversed; for here again there is a distinct representation of the object to be received on a piece of paper, as in the focus of the object-glass, and the eye being situated at any time at this place, which is usually called the distinct base, sees all in confusion; but then let the eye be placed farther from this middle-glass than its focus; it perceives the objects erect and confused: lastly, the third or immediate eye-glass contributes nothing towards the erecting or reverling the species, which it receives erect from the middle eye-glass, no more than in a telescope of two convex-glasses, the eye-glass contributes to the species it receives from the object-glass, as was shewn before: the reason, that this last or immediate eye-glass has nothing to do in the erecting or reverling the species, is the same, as in a telescope of two convex-glasses, viz. the eye is placed in its focus, and therefore sees the species, as represented in the distinct base; that is, the species is inverted in the distinct base of the object-glass, and therefore a single convex eye-glass brings it to the eye inverted; but in the distinct base of the middle, or second eye-glass, the species is erect, and therefore the third or immediate eye-glass brings it to the eye erect: wherefore we

are to consider the telescope, consisting of an object-glass and three eye-glasses, as two telescopes, each consisting of two convex-glasses; the first consists of the object-glass and first eye-glass, and this inverts the species; that is, the species is inverted in the distinct base of the object-glass, and so brought to the eye: the second telescope consists of the two immediate eye-glasses, and this renders erect what the former inverted; that is, the species in the distinct base of the middle eye-glass is erect, and is brought to the eye by the eye-glass; the eye-glasses themselves, in neither case, having any thing to do with the erecting or inverting, but merely representing in the same posture the species immediately before them: therefore, in the last place, one convex-glass, as posited in a telescope, inverts; the second, that is, the first eye-glass does nothing towards erecting or reverling, but represents the image, as it is in the distinct base of the object-glass, that is inverted; the third glass erects, or rather restores, what was before inverted; the fourth represents the image as it receives it from the distinct base of the third, that is, erect.

CONVEX MIRROR. See **MIRROR**.

CONVEXITY, that configuration or shape of a body, on account of which it is denominated convex. See **CONVEX**.

CONVEYANCE, in law, a deed or instrument that passes land, &c. from one person to another.

The most usual conveyances are deeds of gift, bargain and sale, lease and release, fines and recoveries, &c. The words *give* and *grant*, are necessary in a conveyance at common law: but though some maintain that conveyances shall operate according to the words; yet, of late, the judges have a greater regard to the passing of the estate, than to the manner by which it is passed.

CONVICT, in common law, a person that is found guilty of an offence by the verdict of a jury.

CONVICTION, in theology, expresses the first degree of repentance, wherein the sinner becomes sensible of his guilt, of the evil nature of sin, and of the danger of his own ways. See **CONTRITION**.

CONVOCATION, an assembly of the clergy of England, by their representatives, to consult of ecclesiastical matters. It is held during the session of parliament, and consists of an upper and lower house. In the upper sit the bishops, and in the lower the inferior clergy, who are represented by their proctors, consisting of all the deans and archdeacons, of one proctor for every chapter, and two for the clergy of every diocese, in all one hundred and forty-three divines, viz. twenty-two deans, fifty-three archdeacons, twenty-four prebendaries, and forty-four proctors of the diocesan clergy. The lower house chooses its prolocutor, whose business it is to take care that the members attend, to collect their debates and votes, and to carry their resolutions

resolutions to the upper house. The convocation is summoned by the king's writ, directed to the archbishop of each province, requiring him to summon all bishops, deans, archdeacons, &c.

CONVOLVULUS, bindweed, in botany, a genus of plants, whose flower consists of a persistent monophyllous cup, cut at the extremity into five segments; the corolla is monopetalous and campanulate; it hath five subulated filaments, topped with ovate compressed antheræ. The fruit is a roundish capsule contained within the cup, and formed of one, two, or three valves, containing several seeds. There are many sorts of convolvulus, several of which grow wild in this country, and are troublesome weeds. Others, which are natives of foreign parts, are cultivated here for the beauty of their flowers, some of which are so tender as to require a hot-house. Many of the species are twining plants, and most of them are propagated by seeds.

CONVOY, in the marine, any fleet or navy of merchant-ships bound on a voyage to some particular port or rendezvous; or more particularly the ship or ships appointed to conduct and defend them on their passage thither.

CONVOY, in military affairs, a detachment of troops employed to guard any supply of men, money, ammunition, provisions, &c. conveyed in time of war by land to a town, army, or the like.

CONVULSION, *Spasmus*, in medicine, a preternatural and violent contraction of the membranous and muscular parts, arising from a spasmodic stricture of the membranes surrounding the spinal marrow, and the nerves distributed from it, and an impetuous influx of the nervous fluid into the organs of motion.

CONVULSIVE, in medicine, a term applied to those motions which naturally should depend on the will, but are produced involuntarily by some external cause, as a contraction of the muscles, &c. See the preceding article.

CONYZA, flea-bane, in botany, a genus of plants, the compound flower of which is tubulose, consisting both of hermaphrodite and female ones: these last have no flower petals; but the hermaphrodite ones consist of one infundibuliform petal, divided into five patulous segments at the limb: the stamina are five very short capillary filaments: the seeds are solitary, oblong, and crowned with simple downy filaments, and stand in the cup.

The common flea-bane is recommended in the jaundice, to promote the menses, and in the stranguary. Some also make an ointment of its leaves and root, which is said to cure the itch.

COOLER, among brewers, distillers, &c. a large vessel wherein certain liquors are cooled, after having been boiled.

COOLERS, in medicine, those remedies which affect

the organs of feeling with an immediate sense of cold, being such as have their parts in less motion than those of the organs of feeling; as fruits, and all acid liquors: or they are such as, by a particular viscosity, or grossness of parts, give the animal fluids a greater consistency than they had before, and consequently retard their motion; having less of that intestine force on which their heat depends.

Of this sort are cucumbers, and all substances producing viscosity.

COOM, a term applied to the soot that gathers over an oven's mouth; also for that black, greasy substance, which works out of the wheels of carriages.

COOMB, or **COMB of Corn**, a dry measure containing four bushels, or half a quarter. See the article **MEASURE**.

CO-ORDINATE, something of equal order, rank, or degree with another.

COPAL, in natural history, a particular sort of resin brought in irregular lumps from New Spain, where it is said to be obtained from different sorts of large trees, of which eight are described by Hernandez. Some pieces are whitish, semi-transparent, friable, not unlike the finer kinds of common resin grossly powdered and forced together into a mass. Others are more transparent and less friable, and of a yellowish or brown colour. It has a more agreeable smell than frankincense, to which some have resembled it, and does not melt so thin or burn away so fast upon a red hot iron. It does not soften in the mouth, on being chewed, like anime, with which it has been confounded by others. From these and other resinous bodies it differs more remarkably in its being exceeding difficultly dissoluble in rectified spirit of wine.

Solutions of copal have been greatly esteemed as varnishes, and the method of making the solution kept a secret in particular hands. Juncker informs us, that it readily succeeds, if spirit of sal ammoniac, mixed with a due proportion of oil of spike or turpentine, is used for the menstruum.

COPARCENERS, otherwise called *Parceners*, such as have equal portions in the inheritance of their ancestor.

COPE, among ecclesiastical writers, an ornament formerly worn by chantors and sub-chantors, when they officiated in the church solemnity. It is also worn by Romish bishops, and other ordinaries; and reaches from the shoulders to the feet.

COPE, among miners, a duty of six-pence for every load of ore.

COPERNICAN-SYSTEM, is that wherein the sun is placed in the center, and supposed at rest; and that all the primary planets revolve round it, in different periods of time, and at various distances: but yet,

yet, that such is the harmony of the whole, that there is this universal law observed by every one of them, viz. that the squares of the times of their periodical revolutions round the sun are as the cubes of their distances from him. This law likewise obtains amongst the secondary planets, with respect to their primary ones; and is therefore universal throughout the whole system.

In this system, the fixed stars are likewise supposed to be at rest; and that the apparent diurnal motion, which they and the sun appear to have from east to west, is entirely owing to the earth's motion round its axis from west to east; thereby causing the agreeable vicissitudes of day and night.

By whom this system was first invented is not perfectly known: the first revivers of it, that we know of, were Philolaus, Aristarchus, and Pythagoras; and after the last of these it was for some time called: it was also embraced by that able geometrician Archimedes. After him, it was almost forgotten, until the year 1500, when Copernicus revived it, and from whom it has its name. But it was never heartily approved of until the late illustrious Sir Isaac Newton took it in hand, and demonstrated the truth of it, by his theory of gravity, together with the universal law, mentioned above; and from him it is sometimes called the Newtonian system, and that more deservedly than by any other name whatsoever.

Various have been the arguments which have been brought pro and con, with regard to the truth of this system: or hypothesis, and that of Ptolemy, which seems to have been always its most formidable antagonist. As to that of Tycho Brahe, it seems to partake of the inconveniencies of both, without giving a remedy for the defects of either in any great degree; and as it in some particulars partook of both, and, as it were, seemed a kind of moderator between them, it has shared the same fate which the generality of moderators do in warm disputes;—been taken to pieces and despised by both. But what is more strange than all the rest, is, that one and the same argument has been brought to prove both systems; this is the resistance a body would meet with moving in a contrary direction to that of the earth's rotation: the Ptolomaic instancing the flights of a bird east, which is as easily and expeditiously performed as the contrary way, although the motion of the earth is much swifter than the flights of any bird whatsoever; and, therefore, say the friends to this system, the bird would be so far from arriving at any place east of that it took flight from, that it would in reality be left behind. The Copernican fetches his example from the case of a ship sailing to and from the East-Indies; which is performed thither in three months, and is generally fix in returning; and therefore it must be forwarded thither, and retarded in its return by the motion of the earth from west to east. (See Varenus's Syll. of Geography.) We must confess the Copernican

has here greatly the worst of the argument; for his example is not only exaggerated, but even absurd; for the motion of the earth must equally affect the ship, and the place it is bound to; and, therefore, can never prove the motion of the earth. The truth is, the difference in those voyages proceeds from another cause. But the Ptolemaic has no great reason to boast of his superiority; for he does not consider, that the circumambient air is, by the motion and attraction of the earth, carried round along with it; and, consequently, that it communicates the same effect to the bird, or any other body whatsoever: the truth of which may be verified by a great number of familiar experiments; but the two following may suffice.

I. Convey one, or any number of flies into the cabin of a ship under sail, and, when they are set at liberty, and suffered to fly about, it may easily be observed they make their flight with as much ease towards the head of the ship, as they can towards the stern, let the ship's motion be ever so swift.

II. Take a bottle filled with water, and cork it up tight, and through the cork pass a fine capillary tube, such that, when the bottle is inverted, the water shall only drop through; fix it to the top of the cabin of a ship under sail, and place another bottle with a straight neck exactly under it, and you will find that all the drops of water will fall into this bottle, and not beside it, towards the stern of the ship, although the ship will move several inches while the drop is in the air.

We shall next give the reason why this system is now so generally received and approved, almost by every man of sound learning and judgment, together with our own remarks, and that without any partiality on either side of the question.

1. It is most simple, and agreeable to the tenor of nature in all her actions; for by the two motions of the earth, all the phenomena of the heavens are resolved, which, by other hypotheses, are inexplicable, without a great number of other motions contrary to philosophical reasonings. See the articles PTOLEMAIC and TYCAONIC SYSTEM.

Remark. This we think a very strong and unanswerable argument.

2. It is more rational to suppose that the earth moves round the sun, than that the huge bodies of the planets, the stupendous body of the sun, and the immense firmament of stars, should move round the inconsiderable body of the earth, every twenty-four hours.

3. But that harmony which upon this supposition runs through the whole solar system, wonderfully confirms this hypothesis, viz. that the motions of all the planets, both primary and secondary, are governed and regulated by one and the same law, which is, that the squares of the periodical times of the primary planets, are to each other as the cubes of their distances from the sun; and likewise the squares
of

of the periodical times of the secondaries of any primary, are to each other as the cubes of their distances from that primary. Now the moon, which, in the Copernican system, is a secondary of the earth, in the other hypothesis is a primary one: and so the rule cannot take place, because the periodical time, considered as that of a primary one, does not agree therewith. See the article *MOON, PERIOD, &c.*

4. Again, this single consideration Mr. Whiston thinks enough to establish the motion of the earth for ever, viz. If the earth does not move round the sun, the sun must move with the moon round the earth. Now the distance of the sun, to that of the moon, being as 10,000 to 46, and the moon's period being less than 28 days, the sun's period would be found no less than 242 years; whereas, in fact, it is but one year.

5. The sun is the fountain of light and heat, which it irradiates through all the system, and therefore it ought to be placed in the center, so that the planets may at all times have it in an uniform and equable manner.

6. For if the earth be in the center, and the sun and planets revolve about it, the planets would then, like the comets, be scorched with heat, when nearest the sun, and frozen with cold in their aphelia, or greatest distance, which is not to be supposed.

7. If the sun be placed in the center of the system, we then have the rational hypothesis of the planets being all moved about the sun, by the universal law or power of gravity arising from his vast body, and every thing will answer to the laws of circular motion and central forces; but otherwise we are wholly in the dark, and know nothing of the laws and operations of nature.

Remark. These are all very sensible and strong proofs, but cannot amount to a mathematical demonstration.

8. But happily we are able to give not only reasons, but demonstrative proofs, that the sun does possess the center of the system, and that the planets move about it at the distance and in the order assigned in this and in other places. See the article *DISTANCE*.

The first is, that Mercury and Venus are ever observed to have two conjunctions with the sun, but no opposition, which could not happen, unless the orbits of these planets lay within the orbit of the earth.

Remark. This is accounted for by Ptolemy, as will appear from our remark on the 13th.

9. The second is, that Mars, Jupiter, and Saturn, have each their conjunctions and oppositions to the sun alternately and successively, which could not be, unless their orbits were exterior to the orbit of the earth.

Remark. This will also follow from Ptolemy's system.

10. In the third place, the greatest elongation or distance of Mercury from the sun, is about 20° , and that of Venus 47° ; which answers exactly to their distance in this system, though in the Ptolemaean system they might, and would, sometimes be seen 180° from the sun, viz. in opposition to him.

Remark. The latter part of this is false; and the former part of this article is true, in the Ptolemaean hypothesis as well as the Copernican, as will appear from our remark on the 13th article.

11. Fourthly, in this disposition of the planets they will all of them be sometimes much nearer to the earth than at others; the consequence of which is, that their brightness and splendor, and also their apparent diameters, will be proportionally greater at one time than another; and this we observe to be very true every day. Thus the apparent diameter of Venus, when greatest, is near $66''$, but when least, not more than $9''$ and a half; of Mars, when greatest, it is $21''$; but when least, no more than $2''$ and a half; whereas, by the Ptolemaean hypothesis, they ought always to be equal.

12. The fifth is, that when the planets are viewed with a good telescope, they appear with different phases, or with different parts of their bodies enlightened. Thus Venus is sometimes new, then horned, and afterwards dichotomized, then gibbous, afterwards full, and so increases and decreases her light in the same manner as the moon, and as the Copernican system requires.

Remark. The Ptolemaic system, by their epicycles account, in some sort, for these appearances, though not in the same proportions or places, and therefore the strength of these arguments remain the same.

13. The sixth is, that the planets, all of them, do sometimes appear direct in motion, sometimes retrograde, and at other times stationary. Thus Venus, as she passes from her greatest elongation westward, to her greatest elongation eastward, will appear direct in motion, but retrograde as she passes from the latter to the former; and when she is in those points of greatest distance from the sun, she seems for some time stationary: all which is necessary upon the Copernican hypothesis, but cannot happen in any other.

Remark. This argument, though so particularly insisted on by the modern Copernicans, is absolutely, and in every respect, accounted for by the advocates of Ptolemy, in the following manner.

Let BC, DE, and FG, (Plate XXXIX. fig. 1.) be parts of the orbits of the Sun, Venus, and Mercury, respectively, O, the Sun, moving in his orbit from C towards B. Now Ptolemy supposed that two points, ξ and M, in the orbits of Venus and Mercury respectively, and which were the centers of the epicycles of those planets, moved in such a manner as to be always in a right line drawn thro' the Earth and Sun, viz. T O; now if the diameter

ter of Venus's epicycle, in which she was supposed to move, was equal to, or bore such a proportion to her orbit in the Copernican system, as her distance from the earth in one, bore to it in the other system, be it what it would; it is evident that Venus would have her greatest elongations at V and v, be retrograde in passing through that part of her epicycle next the earth; stationary at the points V and v; and be direct during her passage through that part of her epicycle, which is farthest from the earth, equally the same as in the Copernican system.

The same will hold good with regard to Mercury, as is evident from the figure.

14. The seventh is, that the bodies of Mercury and Venus, in their lower conjunctions with the sun, are hid behind the sun's body, and in the upper conjunctions are seen to pass over the sun's body, or disk, in form of a black round spot, which is necessary in the Copernican system, but impossible in the Ptolemaean system.

Remark. This is a strong and convincing proof of the truth of the Copernican system.

15. The eighth, and last, is, that the times in which these conjunctions, oppositions, stations, and retrogradations of the planets happen, are not such as they would be were the earth at rest in its orbit, but precisely such as would happen were the earth to move, and all the planets in the periods assigned them; and therefore this, and no other, can be the true system of the world.

Remark. This is equally false with the thirteenth.

16. But to all those we may add, the aberration of light, lately discovered by that excellent and indefatigable astronomer, the late Dr. Bradley, and which we think is poor Ptolemy's *ne plus ultra*: it amounts to a mathematical demonstration of the truth of the Copernican system; for it is evident, [see the article *ABERRATION*] that if the earth had not a motion on its axis from west to east, there could not be such a thing as the aberration of light existing in nature.

COPERNICUS, the name of an astronomical instrument, invented by Mr. Whiston, to exhibit the motion and phenomena of the planets, both primary and secondary. It is built upon the Copernican system, and for that reason called by this name. It consists of several concentric circles of wood, upon which are inscribed numbers, transferred hither from the astronomical tables; by the various disposition of these circles, which are made so as to slide within each other, questions are solved so as to save long calculations. To exhibit eclipses there is a particular apparatus, consisting of a terrestrial globe, so disposed, as that, being turned round its axis, the light of the sun, or a candle projected through a glass plane, marked out into concentric circles, expresses the digits of the eclipse:

and thus is the path of the eclipse, with its degree or quantity in any part of the path, represented with great accuracy.

The inventor of this instrument has wrote a treatise purposely to explain it.

COPHTS, COPHTI, or COPTS, a name given to such of the Christians of Egypt, as are of the sect of Jacobites.

COPHTIC, or COPTIC LANGUAGE, is that spoke by the Cophts, being the ancient language of the Egyptians, intermixed with the Greek, and the characters of it being those of the Greek.

COPTIC MONKS, religious, among the Christians of Egypt, who have the highest veneration for a monastic life, considering it as the philosophy of the law of Jesus Christ, and the monks as terrestrial angels, or celestial men. They are obliged to part with their possessions, to renounce marriage for ever, to live in deserts, to be clothed in wool, and to eat no meat.

COPING, or COPPING of a Wall, in architecture, the top or covert of a wall, made sloping, to carry off the wet.

COPING over, in carpentry, a sort of hanging over, not square to its upright, but bevelling on its under side, till it ends in an edge.

COPIVI, or Balsam of COPIVI. See the article BALSAM.

COPPEL, COPEL, or CUPPEL, a chemical vessel made of earth, pretty thick, and of the form of a platter or dish.

It sustains the highest degree of fire, and retains all fused metals: but in it all the fusible portions of any metal, when mixed with fused lead, are carried off, except gold and silver, which are left behind in small globules. See ASSAYING.

COPPELLING, or CUPPELLING, in chemistry, is the putting metallic substances into a coppel, or covered vessel, made of bone-ashes, and set in a naked fire, to try what gold or silver they will afford.

COPPER, *Venus*, in natural history, a reddish metal, easily tarnishing in a moist air, and contracting a green or a bluish green rust. It is the most elastic and sonorous of all the metals, and the hardest of all but iron. It spreads difficultly under the hammer, but may be extended to a great degree, drawn into fine wire, and beat into thin leaves. Its specific gravity is near nine times greater than that of water.

It requires for its fusion a strong white heat, greater than that in which gold and silver melt, though not so great as that which is requisite for the fusion of iron. When melted, it is remarkably impatient of moisture: the contact of a little water occasions the melted copper to be thrown about with violence, to the great danger of the by-standers. It may nevertheless be granulated, like other metals, by cautiously pouring a very little at a time into water.

Kept in a heat below fusion, it contracts on the surface thin powdery scales, which, if rubbed off, are succeeded by fresh ones, till the whole quantity of the metal is thus slowly changed into a dark reddish scoria or calx. This does not melt in the greatest degree of fire that our furnaces are capable of giving; but in the concentrated solar heat, it runs easily into a deep red and almost opaque glass. A flaming fire, and a strong draught of air over the surface of the metal, promote its calcination: the flame being tinged of a green, bluish, or rainbow colours, is a mark that the copper burns.

Copper is exceeding rarely found pure in the earth. Of its ores there is a great variety, intermixed with different stony matters, generally abounding with sulphur, sometimes containing a little arsenic. These ores are often of beautiful colours, blue, red, green, yellow, variegated like the rainbow or peacock's tail, most commonly green or blue: they are of all ores, the most beautiful. The lapis lazuli, from which the precious blue pigment called ultramarine is prepared, is one of the ores of this metal. Some of them contain no metal but copper; many have an admixture of others; and there are few ores of other metals without some portion of copper in them. Copper is of all metals the most difficultly obtained pure from the ore; sulphur adhering to it so strongly, as not to be expelled without long calcination. When copper and iron are blended together in the ore, the copper cannot by any method as yet known, be separated to advantage: a rich copper mine, at Lauterberg in the Hartz forest, lies on this account unworked.

There are ores of copper in almost all parts of the world; in Spain, France, England, Norway, Saxony, Bohemia; but more particularly in Sweden, Hungary, and Transylvania. Japan affords a sort of copper superior to any met with in Europe.

Copper is found also in a vitriolic state, dissolved in certain waters, as at Neusol in Hungary: when iron is put into the water, the dissolved copper separates; a proportionable quantity of the iron being dissolved in its place. The copper, extricated from the liquor, adheres to the iron, and covers its surface with a bright cupreous crust: some have been so far imposed on, as to imagine the iron, by this means, actually transmuted into copper.

COPPER-PLATES for engraving. Plates intended for engraving ought to be formed of the best copper; which can be distinguished only by examining it with regard to the qualities requisite to the constituting it good. Those qualities are, that it should be very malleable, that is, capable of being spread with the hammer, or suffering itself to be rolled or drawn out to the nicest or smallest pieces; that it should nevertheless be firm, and resist even to some degree of hardness, provided no shortness of grain or brittleness attend, but that it be perfectly ductile; and that it be free from any veins,

specks, or dissimilar parts, but of an equal texture through the whole. The redness of copper is a presumptive mark of its being good, but not an infallible one: for though it is in general a proof of the purity of the copper, yet it does not evince that the qualities may not be injured by too frequent fusions, or the calcinations it may have undergone, if, as is frequently the case, it has before been employed in forming some utensil.

The copper being chosen, it must be fabricated into plates of the size demanded, the thickness of which may be in proportion of a line to plates that are a foot by nine inches. These plates must then be well forged and planished by a brazier; which should be done cold: for by managing this operation well, the porosity of the copper may be greatly removed, which is for the most obvious reasons of great consequence. When a plate is forged, it should be examined which side is the most even, and the least flawed or cracked; and then the polishing may be thus performed.

Put the plate upon a board leaning obliquely, and in the bottom of which two nails or points are fixed, to keep it from sliding off; and then take a large piece of grind-stone dipt in water, and rub it very strongly once in every part length-ways, and then the same breadth-ways, keeping it moist with water; and repeat this operation till no hollows appear, nor the least mark made by the hammer in forging, or any other flaws, holes, or inequalities. After this take a piece of good pumice-stone, and rub the plate with it in the same manner as was done before with the grind-stone, till all the scratches and marks made of the grind-stone may, by the pumice-stone, be likewise taken away, and then wash it thoroughly clean. The scratches and marks of the pumice-stone should then be taken out by rubbing the plate in the same manner with a piece of oil-stone, till all the marks and scorings of the pumice-stone be taken out: and the plate should be then washed with water till it be perfectly clean. A proper kind of coal must in the mean time be prepared for finishing the preparation of the plate, which must be done in the following manner:

Take three or four large coals of fallow wood, sound, and without clefts, and place them together in a fire made on a hearth, and cover them with other burning coals; heaping a quantity of red-hot ashes upon them. In this manner let them remain, being subject to only a small access of air, for about an hour and a half: but the time should be greater or less, according to their size, that the fire may penetrate into the innermost part of them, and expel all the smoke that can be driven out; to be certain of which, it is better they should stay in the fire rather longer than is necessary, than that the time should be unduly shortened. When they are fit to be taken out, a vessel of water large enough to hold them should be prepared; and they should

be instantly thrown into it, and left there to extinguish and cool. For this purpose some use urine instead of water; but there is no difference, unless in the disagreeable smell of the latter. The coals being thus prepared, pick out one, or a part of one, sufficiently large, firm, and free from clefts; and holding it fast in the hand, set one of the corners against the plate, and rub it, but without observing any particular direction, to take out the marks or scorings of the oil-stone: but if the coal glide on the surface, and take no effect, it is a proof of its not being fit for the purpose; and another, that is not so faulty, must be used instead of it. This fitness may be thus distinguished; that the coal, if good, being wet, and rubbed on the copper, will seem rough, and grate it with a low murmuring noise. When a good coal is obtained, the operation must be continued, till not the least scoring, flaw, or hole whatever, appears; but if the coal itself, as will sometimes happen, be too hard, and leaves traces or scores of its own forming, a softer one must be chosen, and used in the same manner as the first, to remedy the defects of it, and to procure a perfectly clear and even surface on the plate.

This is the method directed by Le Bossé: but the end may be better answered, by first wearing out the marks of the planishing hammer, by rubbing with emery finely ground; and then, the plate being washed clean, brushing it over with the refiner's aqua-fortis; which must be suffered to lie on till the ebullition it produces begins to decrease; and then washed off, by immersing the plate in water; when it will be found to be brought to a better condition to take the burnish with more certainty, than by the laborious use of so many stones and the coal.

The plate being brought to this state, the polishing must be finished with a steel burnisher, with which it must be strongly rubbed; the best method of moving the burnisher is not to work it lengthways, or breadthways, but in a diagonal direction, or from corner to corner, which will more effectually take out all remains of the former scorings or lines. The copper must be thus burnished till it be as bright as a looking-glass in every part; but if, when the rest is thus bright, some particular spots appear dull, or that any lines remain, such faults should be again worked with the burnisher, till the whole be uniformly shining.

COPPERAS, a name given to the facitious green vitriol. See the article **VITRIOL**.

COPPICE, or **COPSE**, a little wood, consisting of under-woods, or such as may be raised either by sowing or planting.

COPULA, in logic, the verb that connects any two terms in an affirmative or negative proposition; as "Riches make a man happy;" where *make* is the copula: "No weakness is any virtue;" where *is* is the copula.

COPULATION, the act of generation, or the congress of the male and female, otherwise called coition.

COPULATIVE PROPOSITIONS, in logic, those where the subject and predicate are so linked together, by copulative conjunctions, that they may be all severally affirmed or denied one of another. Example, "Riches and honours are apt to elate the mind, and increase the number of our desires."

COPULATIVE CONJUNCTION. See the article **CONJUNCTION**.

COPY, in a law sense, signifies the transcript of any original writing, as the copy of a patent, charter, deed, &c.

COPY, among printers, denotes the manuscript, or original of a book, given to be printed.

COPY-HOLD, a tenure for which a tenant has nothing to shew but the copy of the rolls made by the steward of the lord's court.

COPY-HOLDER, one who is admitted tenant of lands or tenements within a manor, which, time out of mind, by use and custom of the manor, have been demisable and demised to such as will take them in fee-simple or fee-tail, for life, years, or at will, according to the custom of the manor by copy of court-roll; but is generally where the tenant has such estate either in fee or for three lives.

COR, the **HEART**, in anatomy. See **HEART**.
COR CAROLI, in astronomy, an extra-constellated star in the northern hemisphere, situated between the coma Berenices, and ura major, so called by Dr. Halley in honour of king Charles.

COR HYDRA, a fixed star of the first magnitude, in the constellation of hydra.

COR LEONIS, or **REGULUS**, in astronomy, a fixed star of the first magnitude, in the constellation leo.

CORACOBACHIALIS, in anatomy, a muscle that has its origin at the coracoid process of the scapula, and its termination about the middle part of the arm. It serves to lift the arm obliquely outwards.

CORACOHYOIDÆUS, in anatomy, a muscle which having its origin from the upper edge of the scapula, near its neck, ascends obliquely under the mastoidæus, and is inserted in the os hyoides, which it serves to pull obliquely downwards. See the article **HYOIDES**.

CORACOIDES, in anatomy, a small, sharp process of the scapula, so called from its resembling a crow's bill.

The coracoid process in infants, is but a cartilage, afterwards it becomes an epiphysis; and, after this, about the age of sixteen, it is perceived to be a separate bone. It serves to strengthen the articulation of the shoulder, and gives origin to one of the muscles of the arm.

CORACOMANTES, in antiquity, persons who foretold events from their observations on crows.

CORACO-RADIALIS, in anatomy, the same with **biceps**. See **Biceps**.

CORAL, *Corallium*, a hard, brittle, branched substance, resembling the stalk of a plant; usually about the thickness of a goose's quill; full of knots; sometimes straight, and sometimes variously bent; both externally and internally of a deep bright red colour. It is found adhering to rocks and other bodies in the sea, particularly in the Mediterranean; covered with a soft fungous bark, in which is a great number of cells curiously divided, containing a milky juice, with apertures on the surface: this cortical part is separated while fresh and soft. It has been generally referred to the vegetable kingdom; but is more probably the work and the nest of little animals.

Artificial CORAL is made of cinnamon well beaten; a layer whereof is applied on a piece of wood well dried and polished, being first moistened with size: the whole is then again polished, and for varnish rub it over with the white of an egg.

CORAL-TREE. See the article **ERYTHRINA**.

CORALLINE, *Corallina*, in botany, is a genus of submarine plants, consisting of stalks and branches often beautifully ramified, and composed of joints of an oblong figure inserted into one another. The greater part of these are gritty, and of a coral-like matter; but nature varies from this in some of the species, which are of a softer substance.

CORAM NON JUDGE, in law, is a term used where a cause is brought and determined in a court of which the judges there have not any jurisdiction.

CORAN or **ALCORAN**. See the article **ALCORAN**.

CORANA, a kind of phaseolus, or kidney-bean, the down of whose pod is the common cow-itch.

CORBAN is a scripture term for an offering which had life, in opposition to the minchab, which had no life.

CORBEL, in architecture, the representation of a basket, sometimes used to signify the vase of a tambour of the Corinthian column.

CORBEL, or **CORBEIL**, is also used in building, for a short piece of timber, placed in a wall, with its end sticking out six or eight inches, as occasion serves, in the manner of a shoudering piece.

CORCHORUS, *Jews-mallow*, in botany, a genus of plants, whose flower consists of five oblong, obtuse petals, with a pentaphyllous calyx, and hath a great number of hairy filaments, topped with small anthers.

The fruit is a cylindrical pod, with five cells, and contains a number of angular, acuminate, seeds.

CORD, or **CHORD**, several threads, cabled or twisted together by means of a wheel. See the article **ROPE**.

CORD of Wood, a certain quantity of wood for burning, so called because formerly measured with a cord. The dimensions of a statute cord of wood are eight feet long, and four feet high, and four feet broad.

CORDAGE, in general implies all the running rigging of a ship, or all that which is employed to extend, contract, or traverse the sails; it is called *running*, because it passes through blocks, and is frequently hauled in, or slackened as occasion requires. See **RIGGING**.

CORDED, in heraldry. A cross-corded some authors take for a cross wound or wrenched about with cords. See the article **CABLED-CROSS**.

Others, with more probability, take it for a cross made of two pieces of cord.

CORDELIER, in church history, a Franciscan, or religious of the order of St. Francis.

CORDIAL, in medicine, whatever raises the spirits, and gives them a sudden strength and cheerfulness.

CORDON, in fortification, a row of stones made round on the outside, and raised between the wall of the fortress, which lies aslope, and the parapet which stands perpendicular, in such a manner, that this difference may not be offensive to the eye: whence the cordons serve only as an ornament, ranging round about the place, being only used in fortifications of stone-work: for in those made with earth, the void space is filled up with pointed stakes.

CORDWAINERS, a term whereby shoe-makers are denominated in the statutes.

CORED HERRINGS, those caught in autumn on the coast near Yarmouth; which, being rolled in salt, are afterwards brought on shore to be made red-herrings.

CORIANDER, in botany, an umbelliferous plant, with a white, slender, root, from which arises a smooth, pithy, branching stalk. The lower leaves are broad and conjugated; but the upper are deeply cut into five segments. The flowers grow in umbels at the top of the branches, of a whitish purple colour: they are composed of five heart-shaped petals, with the same number of stamina. The fruit is spherical, and divided into two parts, each having an hemispherical concave seed. It is annual, flowers in June, and is a native of the south of France, Spain, and Italy, and cultivated in some parts of England. The smell of the whole plant is strong and aromatic; but not a little disagreeable. The seeds also have, when fresh, a very unpleasant flavour, which, by drying, becomes more mild, and have a sweet agreeable taste. The dried seeds are sometimes employed as a stomachic and carminative; and are accounted good against catarrhs,

tarrhs, flatulencies, worms, the cachexy, and slight obstructions of the glands, and to stop hæmorrhages and fluxes.

CORIARIA MYRTLE, *Sumach*, in botany, a genus of plants producing male and female flowers, on different plants. The flower of each consists of five petals very like the cup. It has no pericarpium; but contains five kidney-shaped seeds, inclosed in the petals.

There are two species in this genus, which grow wild about Montpelier in France, where it is used for tanning leather.

CORINTHIAN, in general, denotes something belonging to Corinth: thus we say, Corinthian bras, Corinthian order, &c.

CORINTHIAN ORDER, in architecture, the fourth order of architecture, according to Scamozzi; but Mr. Le Clerc makes it the fifth, being the most noble, rich, and delicate of all the other five.

Most authors ascribe the invention of this order to Callimachus, a Corinthian sculptor. Vitruvius, however, opposes this opinion, and will have the Corinthian capital to have been derived from an order in Solomon's temple, the leaves whereof were those of the palm-tree. The Corinthian order has several characters by which it is distinguished from the rest. Its capital is adorned with two rows of leaves, between which arise little stalks, or caulicoles, of which the volutes are formed, which support the abacus, and are sixteen in number. See **ABACUS**.

CORION, in botany, the same with the coriander. See **CORIANDER**.

CORIS, or **COWRIES**, in commerce. See the article **COWRIES**.

CORIS, in botany, a plant which grows wild about Montpelier, and in most places in the south of France. The flower consists of a single ringent petal: the tube is cylindrical, and of the length of the cup; the limbs are divided into five oblong segments. The fruit is a globose capsule, formed of five valves, and situated in the bottom of the cup. The seeds are small, numerous, and oval.

CORISPERMUM, in botany, a genus of plants whose flower consists of two compressed, crooked-pointed petals, which are placed opposite to each other, and are equal, and contains a single stamen. The germen is compressed and pointed, supporting two capillary styles, each topped with an acute stigma: the germen afterwards becomes an oval compressed seed, with an acute margin.

CORK-TREE, in botany, a species of the quercus or oak. The cork-tree has a long thick, hard root, that produces a middle-sized tree, with a thick trunk, and a few branches. It has a thick, light, pungy bark, of a yellowish grey colour. The leaves are oblong, oval, about two inches long, and one and a quarter broad; they are undivided and awed on their edges, and have a little down on their

under sides. These leaves continue green through the winter till the middle of May, when they generally fall off just before the new leaves come out. The acorns are very like those of the common oak, and is a native of the southern parts of Europe.

The exterior bark of this tree is the cork; it is taken off every eight or ten years; but there is an interior bark which nourishes the tree; so that stripping off the outer, so far from injuring the tree, that it is necessary to continue them in health. In the month of July, the inhabitants of the places where they grow make an incision round both the top and root of the tree, and another longitudinally; when it is thus got off, they unwrap before a fire, and press it flat with weights, after which, they clean it, and export it to other countries.

The cork should be chosen in fine boards, all of a piece, not full of knots or chinks, of a moderate thickness, yellowish without and within, and that which cuts even.

Its use is too well known to need any account of it: in medicine it is of service to stop bleeding, being reduced to powder, or put into some astrigent liquor: burned and mixed with the unguentum populeum, it is very proper for the piles. The Spaniards burn cork into an extraordinary fine black, called Spanish black, which is used for several sorts of work.

CORK, or **CORKING of a Saddle**, the pieces to which the bolsters are made fast; so called as having formerly been made of cork.

CORMORANT, in ornithology, the English name of a species of pelican, with fourteen long feathers in the tail, and the under part of the body whitish: it is a sea-fowl, almost equal to a goose in size, and feeds on fish. All the writers on birds have described it under the names of *carbo aquaticus*, or *corvus aquaticus*.

CORN, in agriculture, the grain or seeds of divers plants; with us the principal are those of wheat, barley, oats, and rye. See the articles **WHEAT**, **BARLEY**, &c.

Corn is very different from fruits, with respect to the manner of its preservation; and is capable of being preserved in public granaries for pressing occasions, and being kept many years. See the article **GRANARY**.

Corn likewise makes the first part of the English name of several plants, on account of their growing among corn. Thus we call the *gladiolus*, corn-flag; the *chrysanthemum*, corn-marigold; the *sison*, corn-parley; the *valeriana*, corn-salad, &c. See the articles **GLADIOLUS**, **CHRYSAETHMUM**, &c.

Indian CORN. See the article **ZEA**.

CORN-MILL, a water-engine for grinding of corn. See **MILL** and **GRINDING**.

CORN, in medicine and surgery, a hard tubercle, like a flat wart, growing in several parts of the feet, especially upon the joints of the toes. This disorder

is not unjustly attributed to the wearing of too straight or narrow-toed shoes, which never fail to produce these tubercles, especially if the person is obliged to stand or walk much, and in the summer-time.

Various are the methods used for removing these callosities of the skin and cuticle; some by knife, and others by application of emollient and caustic or eroding medicines; but which way soever they are removed, it is certainly the best to let their hard substance be first sufficiently mollified; and this may be obtained by frequently macerating them for a considerable time in warm water, and afterwards paring off their uppermost surface with a penknife: or if this does not suffice, let a plaster of green wax, gum ammoniac. de saphon. &c. or a leaf of house-leek be applied and renewed every day; when these applications have been continued for some time, peel them away with your nails, or scrape them with a scalpel, but with great caution, to avoid injuring any of the subjacent tendons of the extensor muscle, which might occasion violent pains, inflammation, convulsions, a gangrene, and even death; all which have also been frequently the consequences of caustics penetrating to those parts.

CORNAGE, an ancient tenure, the service whereof was to blow a horn when any invasion of the Scots was perceived.

CORNEA TUNICA, in anatomy, the second coat of the eye, so called from its substance, which resembles the horn of a lanthorn. See the article **EYE**.

The cornea is convex, pellucid, and divisible into various lamellæ. It is situated in the fore-part of the eye, and surrounded by the sclerotica. It has a most exquisite sense, to the end that the tears, upon the least pain, may be squeezed out of the lachrymal gland, to wash off any filth, which, by sticking to the cornea, might render it dim.

CORNEL TREE, *Cornus*, in botany. See the article **CORNUS**.

CORNELIAN, *Sarda*, the same with carnelian. See **CARNELIAN**.

CORNER, *Angulus*, in a general sense, the same with angle. See **ANGLE**.

CORNER-TEETH of a Horse, the four teeth between the middle teeth and the tusks, being two above and two below, in each side of the jaw, which shoot forth when the horse is four years and a half old.

CORNET, in the military art of the ancients, an instrument much in the nature of a trumpet, which, when it only sounded, the ensigns were to march alone, without the foldiers; whereas, when the trumpet only sounded, the foldiers were to move without the ensigns.

CORNET, in the military art of the moderns, the third commission officer in a troop of horse or dragoons.

This is a very honourable post: he commands in the lieutenant's absence; his principal duty being to carry the standard near the middle of the first rank of the Squadron.

CORNICHE, **CORNISH**, or **CORNICE**, in architecture, the uppermost member of the entablature of a column, as that which crowns the order. The cornice is the third grand division of the tra-beation, commencing with the frieze, and ending with the cimati-m. The cornice is different in different orders, there being as many kinds of cornices as there are different orders of columns. It is most plain in the Tuscan order. Vignola makes it consist of an ovum or quarter-round, an astragal or baguette, the reglet or fillet, the larmier, and the talon.

In the Ionic, the members are in most respects the same in the Doric, except that they are frequently enriched with carvings, and have always dentils.

In the Doric, Vignola makes the capitals of the triglyphs of the frieze, with their bandeletters, a talon, mutules or dentils, a larmier with its guttæ underneath, a talon, fillet cavetto, and reglet.

The Corinthian cornice is the richest, and is distinguished by having both modillions and dentils, contrary to the opinion of Vitruvius, who looks upon these two ornaments as incompatible; and of Mr. Le Clerc, who accounts the dentils as peculiar to the Ionic.

In the Composite there are dentils, its modillions carved, and there are channels under the fillet.

CORNICE is also used, in general, for all little projectures in masonry or joinery, even where there are no columns, as the cornice of a chimney, beaufet, &c.

Architrave-CORNICE, that immediately contiguous to the architrave, the frieze being retrenched.

Mutilated CORNICE, one whose projecture is cut, or interrupted to the right of the larmier: or reduced into a plat-band, with a cimati-m.

Cantaliver CORNICE, a term used by workmen for a cornice that has cantalivers underneath.

Coving-CORNICE, that which has a great casket or hollow in it, ordinarily lathed and plastered upon compass-sprechts, or brackets.

Modillion-CORNICE, one with modillions under it.

CORNICE is also used for the crownings of pedestals.

CORNICULARIS PROCESSUS, the process or knob of the shoulder bone, called thus because it resembles the figure of a crow's beak.

CORNICULARIUS, in Roman antiquity, an officer of the army, appointed to assist the military tribune in quality of lieutenant.

CORNICULATE, or **CORNICULATED FLOWER**, one with a sharp-pointed appendage, resembling, in some degree, a cock's spur.

CORNI-

CORNICULATE PLANTS, the same with filiquose plants with horned pods, or seed-vessels.

CORNISH, or **CORNICHE**, in architecture. See the article **CORNICHE**.

CORNU AMMONIS, or **HAMMONIS**, in natural history, a genus of fossil shells, called serpent-stones, or snake-stones, by the vulgar.

They are found of all sizes, from the breadth of a six-pence, to more than two feet in diameter; some of them rounded, others greatly compressed, and lodged in different strata of stones and clays; some again are smooth, and others ridged in different manners, their striae and ridges being either straight, irregularly crooked, or undulated.

CORNUCOPIA, or **HORN of Plenty**, among painters, &c. is represented under the figure of a large horn, out of which issues fruits, flowers, &c. Upon medals the cornucopia is given to all deities, geni, and heroes, to mark the felicity and abundance of all the wealth procured by the goodness of the former, or the care and valour of the latter.

CORNUCOPÆ, in botany, a genus of plants, producing a flower, the corolla of which is univalicular, and contains three capillary filaments, topped with oblong antheræ; the germen is turbinate, and supports two hairy styles; it has no pericarpium, but the corolla incloses a single turbinate seed, convex on one side and plane on the other.

CORNUS, the cornel tree, in botany, a genus of plants, whose flowers come out in bunches, placed on a general involucre, which is coloured; each flower consists of four oblong, acute, plane petals, with four erect stamina. The fruit is a roundish umbilicated drupe, inclosing a cordated or oblong nut with two cells, having an oblong kernel. There are several species of cornus, one of which is known by the name of cornelian cherry. This tree is moderately tall with many irregular branches; the trunk is covered with a pale brown bark, and the young twigs are of a bloody purple; the leaves are oblong, considerably broad and ribbed, with high veins; it flowers early in the spring before the leaves appear, and are placed on the extremities of the branches. It is propagated in the nurseries as a flowering shrub, on account of the early appearance of the flowers. The fruit is ripe in September, and are preserved by many for the making of tarts; when full ripe they are of a sweetish acid, and are reckoned cooling, drying, and astringent, for which reason they are prescribed against fluxes of all kinds, and are good in fevers, especially if attended with a diarrhæa.

COROLLA, among botanists, the most conspicuous, and in general the most beautiful part of a flower. This is the termination of the liber or inner bark, continued to, and accompanying the fructification in this new form of painted leaves, most commonly called petals, by which appellation they are distinguished from the green leaves of the plant.

Its use is the same as that of the calyx, serving more immediately to protect the generative parts, as the calyx, which is usually of a stronger texture, covers the whole. According as there is one, two, or three of these petals, the corolla is said to be monopetalous, dipetalous, tripetalous, &c. but in some flowers the corolla is wanting, which are then said to be apetalous.

COROLLARY is an useful consequence drawn from something already advanced or demonstrated: thus, it being demonstrated that a triangle which has two equal sides, has also two angles equal; this corollary will follow, that a triangle which has three sides equal, has also its three angles equal.

COROLLISTS, *Corollistæ*, an appellation given by Linneæus to those botanists who have arranged plants under distinct classes, according to the different form of their corollæ or flowers; such is the celebrated Tournefort and Rivinus.

COROLLULA, a term used by botanists, to express little partial flowers, which together make up the compound ones.

These corollulæ are of two kinds, the tubulated and ligulated; the former whereof are always furnished with a campanulated limb, divided into four or five segments; and the latter have only a flat linear limb, terminated by a single point, or by a broader extremity, divided into three or five segments. See **FLOWER**.

CORONA, **CROWN**, or **CROWNING**, in architecture. See **CROWNING**.

CORONA, among anatomists, denotes that edge of the glans penis where the preputium begins.

CORONA, among botanists, expresses any thing growing on the head of a seed.

These coronæ are of various kinds: sometimes simple, consisting only of a dentated membrane; sometimes pappose, consisting of downy matter, which in some cases is immediately affixed to the seed; in others it has a pedicle growing from it; and it sometimes is composed of simple filaments, and sometimes is ramose. Hence, in the description of the seeds of plants, they are frequently said to be crowned or winged with down; the use of this part being evidently to scatter and disperse the seeds, when ripe.

CORONA BOREALIS, in astronomy, is a constellation in the northern hemisphere, situated between Bootes and Hercules, near the head of Serpens. The poets tell us, this was the crown or garland that Venus gave to Ariadne when she was married to Bacchus, in the isle of Naxos, after Theseus had forsaken her; and afterwards Bacchus placed this crown in heaven in token of his love. Novidius will have it to be the crown of the Virgin Mary. The stars in this constellation, according to Ptolemy's catalogue, are eight, Tycho's the same, and in the British twenty-one; their right ascension, declination, variation, &c. are as follows.

Order

Order.	Magn.	Name.	Right Ascension	Distance from Nor. Pole.	Var. in Right Ascen.	Var. in Declination.
1	6	ρ	227.33.21	59.29.50	36.2	13.5
2	5	γ	228.18.34	58.50. 8	36.0	13.2
3	4	β	229.28.18	60. 3.27	36.2	13.0
4	4.5	θ	230.48.38	57.49.15	35.9	12.8
5	2.3	α	231. 8.25	62.28. 8	38.5	12.6
6	5	μ	231.37.49	50.11.34	31.0	12.0
7	4	ζ	232.38.59	52.34.29	36.0	11.9

CORONA AUSTRALIS, in astronomy, a constellation of the southern hemisphere, between the fore legs of Sagittarius. The opinion of the poets are various concerning this crown: some say this is the crown that was given to Sagittarius by the gods, and which he was wont to wear; but one day casting it from him out of giddiness, or with great indifference, it gave such offence to the donors, that they placed it betwixt his fore legs, for a chastisement for his behaviour, and a memento for others, not to despise or think triflingly of the gifts of their superiors. Others, call it the wheel of Ixion, thinking it to be that wheel on which he was tortured for his attempt on Juno's virtue, for which impudence Jupiter hurled him down from heaven into hell, where this punishment was inflicted; but afterwards the wheel was made a constellation, to betoken to mortal man, the great sin he commits who attempts the virtue of another man's wife.

CORONAL, *Coronalis*, in anatomy, the first future of the skull. See the articles **SUTURE** and **SKULL**.

This future reaches transversely from the one temple to the other, and joins the os frontis with the ossa parietalia.

CORONALE OS, in anatomy, the same with the os frontis. See **FRONTIS**.

CORONARY VESSELS, *Vasa Coronaria*, in anatomy, certain vessels which furnish the substance of the heart with blood.

CORONARY ARTERIES, are two arteries springing out of the aorta, before it leaves the pericardium.

CORONARY VEIN, a vein diffused over the exterior surface of the heart. It is formed of several branches arising from all parts of the vascus, and terminates in the vena cava, whither it conveys the remains of the blood brought by the coronary arteries.

Stomachic CORONARY, a vein inserted into the trunk of the splenic vein, which, by uniting with the mesenteric, forms the vena porta. See the article **PORTA**.

CORONE, in anatomy, the anterior apophysis of the lower jaw. See **JAW**.

CORONER, an ancient officer of the kingdom, so called, because he is wholly employed for the king and the crown.

CORONET. See the article **CROWN**.

CORONET, or **CROWN** of a *Horse*, the lowest part of the pastern, which runs round the coffin, and is distinguished by the hair joining and covering the upper part of the hoof.

CORONILLA, in botany, a genus of plants, whose flower is papilionaceous; the vexillum cordated, bent backwards, and scarce longer than the alæ, standing in clusters at the top of the branch; the fruit is a taper jointed pod, inclosing several seeds.

CORPORA CAVERNOSA, in anatomy. See the article **CAVERNOSE**.

CORPORA OLIVARIA, two protuberances of the medulla oblongata. See the article **BRAIN**.

CORPORA PYRAMIDALIA, two protuberances of the under part of the cerebellum, so called from their resemblance of a pyramid.

CORPORA STRIATA, two protuberances in the lateral ventricles in the brain. See the article **BRAIN**.

CORPORAL of a ship of war, an officer under the master at arms, employed to teach the sailors the exercise of small arms, or musketry, to attend at the gangway, or entering ports, and observe that no spirituous, or intoxicating liquors, are brought aboard, unless for the officers, or by their leave: some of the sea-nymphs however, who are dextrous at conveyances of this kind, often elude their search, by concealing quantities of gin, &c. in bladders so cautiously, that the corporal's modesty, though but little, relieves these ladies from a closer scrutiny.

The corporal is also to extinguish the fire and candle at eight o'clock in winter, and nine in summer, at which time the gun is fired, and to walk down in the lower-decks, once or twice in an hour, to see that there are no lights but such as are under charge of proper centinels.

CORPORAL, an inferior officer under a serjeant, in

in a company of foot, who has charge over one of the divisions, places and relieves centinels, and keeps good order in the corps de garde: he also receives the word from the inferior rounds, which passes by his corps de garde: there are generally three corporals in each company.

CORPORAL, *Corporale*, in the Christian church, a name for the linen cloth thrown over the consecrated elements at the celebration of the eucharist.

CORPORATION, a body politic, or incorporate, so called, because the persons or members are joined into one body, and are qualified to take and grant, &c.

CORPOREAL, those qualities which denominate a body.

CORPOSANT, COMPOZANT, or COMPOSANT, a sort of volatile meteor, or *ignis fatuus*, often seen about the decks or rigging of a ship, but particularly the extremities, as the mast-heads and yard-arms, in a violent storm, accompanied with rain and a dark night. We have seen three of these at once in such a situation ourselves, when the least glimmer of light could not be discovered any where else. By some these are called Castor and Pollux. See **CASTOR**, &c.

CORPS DE GARDE, a post in an army, sometimes under covert, sometimes in the open air, to receive a number of soldiers, who are relieved from time to time, and are to watch in their turns, for the security of some more considerable post.

Corps de garde is frequently used for the men who watch in this post.

CORPS DE BATAILLE, the main body of an army, drawn up in order of battle. See the articles **ARMY** and **GUARD**.

CORPS, in architecture, a term to signify any part that projects or advances beyond the nakedness of a wall, serving as a ground for some decoration, or the like.

CORPULENCY, in medicine, the state of a person too much loaded with flesh or fat.

CORPUS CALLOSUM, a medullary part of the brain, which covers the whole lateral ventricles. See the article **BRAIN**.

CORPUS CAVERNOSUM, a cavernous substance surrounding the vagina, which swells in the time of coition.

CORPUS PAMPINIFORME, a body formed a little above the testicles, by the division and reunion of the spermatic veins.

CORPUS is also used, in matters of literature, for several works of the same nature, collected together in the form of a system of any art or science.

CORPUS CHRISTI, a festival of the church, kept on the next Thursday after Trinity-Sunday, instituted in honour of the eucharist; to which also one of the colleges in Oxford is dedicated.

CORFUSCLE, in physics, a minute particle, or physical atom, being such as compose a natural

body. By this word is not meant the elementary particles, nor the hypostatical principles of chemists; but such particles, whether of a simple or compound nature, whose parts will not be dissolved nor dissipated by ordinary degrees of heat. Sir Isaac Newton, in the second book of his *Optics*, shews a way of guessing, with great accuracy, at the size of the component corpuscles of bodies. See **COLOUR**.

CORPUSCULAR PHILOSOPHY, that way of philosophising which endeavours to explain things, and to account for the phenomena of nature by the motion, figure, rest, position, &c. of the corpuscles, or the minute particles of matter. See the article **ATOMICAL PHILOSOPHY**.

This philosophy is so very ancient, that, both before Epicurus and Democritus, and even before Leucippus taught in Greece, there was a Phœnician philosopher, who explained natural phenomena by the motions and affections of the minute corpuscles of matter, as very old writers inform us: and, therefore, it should rather be called Phœnician philosophy, than Epicurean.

Mr. Boyle sums up the chief principles of the corpuscular hypothesis, which now flourishes under the mechanical philosophy, in these particulars:

1. They suppose that there is but one catholic or universal matter, which is an extended, impenetrable, and divisible substance, common to all bodies, and capable of all forms.
2. That this matter, in order to form the vast variety of natural bodies, must have motion in some or all its assignable parts; and that this motion was given to matter by God, the creator of all things, and has all manner of directions and tendencies.
3. Matter must also be actually divided into parts, and each of these primitive particles, fragments, or atoms of matter, must have its proper magnitude or size, as also its peculiar figure or shape.
4. They suppose also that these differently sized and shaped particles may have as different orders and positions, whereof great variety may arise in the composition of bodies.

CORRECTION, in printing, implies the pointing out, or discovering the faults of a printed sheet, in order to their being amended by the compositor before it is printed off. See **PRINTING**.

The corrections are placed on the margin of every page, right against the line wherein the faults are found; and there are different characters used to express different corrections: thus *A* is put for *dele*, to intimate that something, as a point, letter, word, &c. dashed in that line, is to be taken out. If any thing is to be inserted, the place is to be marked thus *A*, and the thing to be inserted added in the margin. When there are two or more corrections in the same line, then they are all separated in the margin by little bars thus |. If a space be omitted, its place is marked with a caret, and the

margin thus $\#$. When a letter is inverted, it is expressed in the margin thus $\cap$. When any thing is to be transposed, it is directed thus, *Extraordinary scarce ever fail of attainments* exciting envy, for *Extraordinary attainments scarce ever fail of exciting envy*, and in the margin is added *tr*. If Italic characters are to be changed for Roman, or *vice versa*, a line is drawn thus—under the letters, and *rom.* or *ital.* is written in the margin. If a space, or n or m quadrat, stick up, and print black, it is marked in the margin with a dash, thus $\mid$. If a word, sentence, or paragraph is entirely omitted, the place is marked with a caret, and in the margin is put the word *out*. If the letters of a word stand too far asunder, a line is drawn under them, and in the margin is put a crooked line or hook, thus $\cup$. There are many other marks used in correcting, as $\surd$ for superior, *cap.* for capital, *l. c.* for lower-case, &c.

CORRECTION, in the manege, signifies aids given with severity.

CORRECTION, in pharmacy, the adding some ingredient to a composition, in order to check or moderate the violence of the operation.

CORRECTION, in rhetoric. See EPANORTHOSIS.

CORRECTOR, in general, denotes something that mends the faults or bad qualities of others.

CORRECTOR of the Staple, a clerk belonging to the staple, whose business is to write down and record the bargains that merchants make there.

CORRECTOR, in medicine and pharmacy, an ingredient in a composition, which guards against or abates the force of another.

Thus the lixivial salts prevent the grievous velleations of refinous purges, by dividing their particles, and preventing their adhesions to the internal membranes, whereby sometimes they occasion intolerable gripings: and thus spices and carminative seeds also assist in the easier operation of some cathartics, by dissipating collections of wind. In the making a medicine, such a thing is also called a corrector, as destroys or diminishes a quality in it, that could not otherwise be dispensed with: thus turpentine may be called the corrector of quicksilver, by destroying its fluxity, and making it thereby capable of mixture; and thus rectified spirit of wine breaks off the points of some acids, so as to make them become safe and good remedies which before were destructive.

CORRELATIVE, something opposed to another in a certain relation. Thus, father and son are correlatives. Light and darkness, motion and rest, are correlative and opposite terms.

CORRIGIOLA, in botany, a genus of plants, whose corolla consists of five ovated patent petals, with the same number of subulated filaments top'd with simple antheræ; it hath no pericarpium, but the cup, which is pentaphyllous, containing a single ovated triangular seed.

CORROSION, in a general sense, the action of gnawing away, by degrees, the continuity of the parts of bodies.

CORROSION, in chemistry, an action performed on bodies, by means of proper menstrua, that produce new combinations, and a change of their form, without converting them to fluidity. See the article MENSTRUUM.

CORROSIVES, in surgery, are medicines which corrode whatever part of the body they are applied to: such are burnt-alum, white precipitate of mercury, white vitriol, red precipitate of mercury, butter of antimony, lapis infernalis, &c.

CORRUGATOR, in anatomy, a muscle which arises fleshy from the process of the os frontis, next the inner or great angle of the orbit, above the joining of the os nasi and the superior process of the os maxillare with this bone: from thence it runs obliquely outwards and upwards, and is inserted into the fleshy part of the occipito-frontalis, some of its fibrillæ passing through into the skin, a little higher than the middle region of the eyebrows.

Its use is to smooth the skin of the forehead, by pulling it down after the action of the occipito-frontalis; and when it acts most forcibly, it serves to wrinkle the skin of the front between the supercilia, as it happens when we frown, or knit the brows.

CORRUPTICOLÆ, in church history, a sect of heretics, so called from their maintaining that the body of Christ was corruptible, that the fathers had owned it, and that to deny it was to deny the truth of our Saviour's passion.

CORRUPTION, the destruction, extinction, or, at least, cessation for a time, of the proper mode of existence of any natural body.

CORRUPTION of blood, in law, an infection accruing to a man's state, attainted of felony and treason, and to his issue; for as he loses all to the prince, &c. his issue cannot be heirs to him, or to any other ancestor by him: and if he were noble, his heirs are rendered ignoble.

CORSAIR, in the marine, a name given to the piratical cruisers of Barbary, who frequently plunder the merchant-ships of countries with whom they are at peace.

CORSELET, a little cuirass; or, according to others, an armour or coat made to cover the whole body, anciently worn by the pike-men, usually placed in the fronts and flanks of the battle, for the better resisting the enemy's assaults, and guarding the soldiers placed behind them.

CORTEX, bark, in botany; see BARK.

CORTEX Peruvianus. See QUINQUINA.

CORTEX Winteranus. See WINTERANUS Cortex.

CORTICAL, in a general sense, implies something consisting of, or resembling bark. Thus the cortical part of the brain is that which invests the internal

ternal or medullary part, like the bark of a tree. See BRAIN.

CORTUSA, in botany, a genus of plants, the flower of which consists of a monopetalous rotated corolla, and contains five obtuse stamina. The fruit is an ovato-oblong pointed capsule, furrowed longitudinally on each side with valves, having their sides involuted, and one cell containing a number of obtuse oblong small seeds.

CORUSCATION, a glittering, or gleam of light issuing from any thing.

CORVUS, the raven in ornithology, a genus of birds of the order of the pica, the distinguishing character of which is, that the beak is of a convex and cultrated figure, the mandibles nearly equal, and the base bevel with hairs.

CORVUS, in astronomy, a constellation of the southern hemisphere. The fabulous history is this: Apollo making a great entertainment for Jupiter, and after much mirth and feasting (being all joyous souls) he found he should want water, or not have a sufficiency for his present entertainment; whether this water was wanted among the gods to mingle with their wine, or to incorporate with any other divine liquor, we are not able to judge. However Apollo gave a cup to the crow (his favourite bird) and sent him to fetch water therein; but the crow, in his flight towards the river, espied a fig-tree, to which he directed his course, and found the figs not yet ripe: however he would not depart till they were; and after having satisfied his longing, he bethought himself of his errand, and what excuse he should make to Apollo for his long delay. At last seeing a snake, he took it up in his bill, carried it to Apollo, and told him it would not let him fill the cup; for which frivolous excuse, Apollo decreed that the bird should never drink while the figs were unripe on the tree, and as a memorial placed the crow, cup, and snake in heaven.

There are nine stars in this constellation according to the British catalogue; their right-ascension, declination, &c. as follow, viz.

Order.	Magn.	Name.	Bayer Let.	Right Ascension	Distance from Nor. Pole.	Var. in Right Ascen.	Var. in Declination.
1	4		α	$178^{\circ} 0' 59''$	$113^{\circ} 23' 30''$	46.0	20.0
2	4		ϵ	$179.27.39$	$111.10.10$	46.1	20.0
3	6		γ	$179.40.59$	$112.15.55$	46.1	20.0
4	3		δ	$180.53.9$	$106.12.30$	46.2	20.0
5	5			$182.2.39$	$110.52.55$	46.2	20.0
6	6		δ	$182.43.2$	$113.30.25$	46.2	20.0
7	3			$184.23.2$	$105.10.27$	46.6	20.0
8	5		μ	$184.55.48$	$104.51.52$	46.7	20.0
9	3		b	$185.27.36$	$112.4.13$	46.9	20.0

CORVUS, in Roman antiquity, a military engine chiefly used in boarding the enemy's ships.

CORYBANTES, in antiquity, priests of the goddess Cybele, who inspired with a sacred fury, danced up and down, tossing their heads, and beating on cymbals, or brazen drums. They inhabited Mount Ida, in the island of Crete, where they nourished the infant Jupiter.

CORYLUS, the hazle, or nut-tree, in botany. See HAZLE.

CORYMBIFEROUS *Plants*, in botany, are such as have a compound discous flower, but their seeds destitute of down. They bear their flowers in clusters, spreading round in the form of an umbrella. Of this kind are the common marygold, common daisy, camomile, &c.

CORYMBUS, among botanists, clusters of berries, as those of ivy, &c. It is also used by the modern botanists, to signify a compound discous flower, which does not fly away in down.

CO-SECANT, in geometry, is the secant of the complement of any given arch to ninety degrees.

COSMETIC, in medicine, implies a preparation for softening and whitening the skin.

COSMICAL, in astronomy, is one of the poetical risings or settings of a star; which is said to rise cosmically, when it rises with the sun, or with that point of the ecliptic, in which the sun is at that time; and the cosmical setting of a star, is when it sets at sun rising.

COSMOGRAPHY, a description of the several parts of the visible world; and consists of two parts, astronomy and geography.

The word is Greek, *κοσμογραφία*, and compounded of *κοσμος*, the world, and *γραφω*, to describe.

COSMOPOLITE, a citizen of the world, or one who has no fixed residence.

COSSE, or **COSSIE**, a word used, by old writers, for algebra.

COSSET, among farmers, implies a colt, calf, lamb, &c. brought up by hand, without the dam.

COSTAL, an epithet applied by anatomists to several parts belonging to the sides.

COSTIVENESS, among physicians, a preternatural detention of the faces, with an unusual dryness and hardness thereof.

The most effectual method of removing obstructions of this kind, are gentle purgatives; such as the purging salts, manna, lenitive electuary, and emollient clysters.

COSTMARY, in botany, a species of tansey; it grows naturally in the south of France and Italy, but is here planted in gardens, and flowers in August. Its roots are hard, long, stringy, and creep in the ground like those of mint; the leaves are oblong, of a palish colour, and dentated on their edges; the flowers are produced on the top of

the stalks in a loose corymbus, and are of a deep yellow.

The leaves are chiefly used in medicine, and are stomachic, cephalic, carminative, and deobstruent; they are also externally applied in fomentation and bathing, to strengthen the joints.

COSTS, in law, imply the expences of a suit recovered by the plaintiff together with damages.

COSTUME, a rule or precept in painting, by which the artist is enjoined to make every person and thing sustain its proper character, and not only observe the story, but the circumstances, the scene of action, the country or place, and take care that the habits, arms, manners, proportions, and the like, exactly correspond.

COSTUS, in botany, a plant which hath a fleshy jointed root, which propagates under the surface of the ground like that of ginger. From the root arise many round taper herbaceous stalks, which are furnished with oblong smooth leaves, embracing the stalk like those of the reed; these rise about two feet high, and from the center the head of the flowers are produced, which is near two inches long, blunt at the top, and composed of several leafy scales, out of which the flowers come; each of these have but one thin white petal, which is of short duration. The time of its flowering here is quite uncertain. It is propagated by parting the roots in the spring; but being a native of East India, it requires a stove to preserve it in this climate.

The roots of this plant were formerly imported from India, and were much used in medicine; but of late years they have not been regarded, the roots of ginger being generally substituted in their stead.

COTESIAN Theorem, an appellation given to a remarkable property of the circle discovered by Mr. Cotes, of great use in finding the fluents to a vast number of fluxions: the demonstration and application of which may be seen in most books on fluxions, but in our opinion, no where so elegantly done as in the treatise published by the late Mr. Simpson.

COTHURNUS, the buskin. See **BUSKIN**.

COTICE, or **COTISE**, in heraldry, is the fourth part of the bend; and, with us, is seldom, if ever, borne but in couples, with a bend between them.

COTTAGE, a small house, without lands belonging to it.

COTTON, in commerce, a soft downy substance, growing on a tree called gossypium by botanists. See **GOSSYPIMUM**.

Cotton is separated from the seeds of the plant by a mill, and then spun and prepared for all sorts of fine works, as stockings, waistcoats, quilts, tapestry, curtains, &c. With it they likewise make muslin, and sometimes it is mixed with wool, sometimes with silk, and even with gold itself.

Lavender Cotton, a name by which some call

the fantolina of authors. See the article **SANTOLINA**.

COTULA, in botany, a genus of plants whose flower is compounded, a little convex, and radiated. The hermaphrodite florets, which compose the disk, are very numerous and tubulose, with the limb divided into four segments: these have four small stamina; and the seeds are solitary, small, and trigonal. The female florets, which compose the rays, have an oval compressed germen, which is succeeded by single cordated seeds.

COTULA, or **COTYLA**, in antiquity, a liquid measure among the Greeks, equal to the hemina of the Romans, containing half a sextary, or four acetabula: hence it appears, that it contained ten ounces of wine, and nine of oil.

COTURNIX, the quail, in ornithology, a species of tetrao, with the line of the eye-brows white; said to be the least bird of the whole order of the gallinæ.

It is about the size of the fieldfare, and is esteemed at table.

COTYLA, in anatomy, implies any deep cavity in a bone, in which any other bone is articulated: but it is generally used to express the acetabulum, or cavity which receives the head of the thigh-bone.

It also imports a deep sinus surrounded with large lips.

COTYLEDON, navel-wort, in botany, a genus of plants, the flower of which is composed of a campanulated single petal, cut into five segments at the brim, which are reflected. The fruit consists of five oblong, ventricose, acuminate capsules, each formed of a single valve, and opening longitudinally inwards. The seeds are numerous and small.

There are divers species of cotyledon, which are all natives of foreign countries, except one sort, which grows naturally in the west of England; the leaves of which are said to be good in external inflammations; and are sometimes substituted instead of houseleek.

COTYLEDONES, in anatomy, are certain glandular bodies, adhering to the chorion of some animals: but no such substances are observable in human bodies, the placenta in the womb supplying the place thereof in women. See the article **PLACENTA**.

COUCH, in painting, a phrase used for each lay or impression of colour, either in oil or water, where-with the painter covers his canvas, waincot, or other matter to be painted.

COUCH, or **WET-COUCH**, in malt-making. See the article **MALT-MAKING**.

COUCH-GRASS, in botany. See the article **AGROSTIS**.

COUCHANT, in heraldry, is understood of a lion, or other beast, when lying down, but with his

his head raised, which distinguishes the posture of couchant from dormant, wherein he is supposed quite stretched out and asleep.

COUCHE, in heraldry, signifies any thing lying along: thus, chevron couche, is a chevron lying sideways, with the two ends on one side of the shield, which should properly rest on the base.

COUCHING, among sportsmen, denotes the lodging of a boar. See **BOAR**.

COUCHING of a Cataract, in surgery, one of the two chief methods of curing a cataract, by couching with the needle. See the article **CATARACT**.

COVENANT, a compact or agreement made between two or more persons, to perform something.

COVENTRY-BELLS, in botany, a name sometimes used for the campanula. See the article **CAMPANULA**.

COVERING, or **ROOFING**, in architecture. See the article **ROOF**.

CO-VERSED SINE, in geometry, the remaining part of the diameter of a circle, after the versed sine is taken from it. See the article **VERSED SINE**.

COVERT-WAY, or **CORRIDOR**, in fortification, a space of ground upon the edge of the ditch level with the field. It is covered with a parapet, together with its banquets and glacis, ranging quite round the half-moon, and other works towards the country.

COVERTURE, in law, is applied to the state and condition of a married woman, who is under the power of her husband, and therefore called *feme covert*; and disabled to contract with any person to the detriment of herself or husband, without his consent and privity; or allowance and confirmation thereof.

COUGH, *Tussis*, in medicine, a convulsive motion of the diaphragm, muscles of the larynx, thorax, and abdomen, violently shaking, and expelling the air that was drawn into the lungs by inspiration.

COVIN, among lawyers, a deceitful compact between two or more to deceive or prejudice another person.

COVING, in building, is when houses are built projecting over the ground-plot, and the turned projecture arched with timber, lathed and plastered.

COULTER, in husbandry, an iron instrument, fixed in the beam of a plough, and serving to cut the edge of each furrow. See the article **PLOUGH**.

COUNCIL, or **COUNSEL**, in a general sense, an assembly of divers considerable persons to concert measures relating to the state.

Privy COUNCIL, the primum mobile of the civil government of Great-Britain, bearing part of that great weight in the government which otherwise would be heavy upon the king.

It is composed of eminent persons, the number of whom is at the sovereign's pleasure, who are bound by oath to advise the king to the best of their judgment, with all the fidelity and secrecy that becomes their station. The king may declare to, or conceal from, his privy council whatever he thinks fit, and has a select council out of their number commonly called the cabinet council, with whom his majesty determines such matters as are most important, and require the utmost secrecy. All proclamations from the king and the privy-council ought to be grounded on law, otherwise they are not binding to the subject.

Privy-counsellors, though but gentlemen, have precedence of all the knights and younger sons of barons and viscounts, and are styled right honourable.

COUNCIL of War, an assembly of the principal officers of an army or fleet, occasionally summoned by the general or admiral to concert measures for their conduct in any hostile enterprise. It is not much to the advantage of a state to have too many councils of war.

Councils of war are also sometimes called when the officers have no inclination to land on an enemy's coast; in this case they find it necessary to foresee great danger in the attempt.

COUNCIL, in church history, an assembly of prelates and doctors met for the regulating matters relating to the doctrine, or discipline, of the church.

National COUNCIL, is an assembly of prelates of a nation under their primate or patriarch. See **PRIMATE**, &c.

Oecumenical or general COUNCIL, is an assembly which represents the whole body of the universal church. The Romanists reckon eighteen of them; Bullinger, in his treatise de Conciliis, six; Dr. Prideaux, seven; and bishop Beveridge has increased the number to eight, which, he says, are all the general councils which have ever been held since the time of the first Christian emperor. They are as follows: The council of Nice, held in the reign of Constantine the Great, on account of the heresy of Arius. 2. The council of Constantinople, called under the reign, and by the command of Theodosius the Great, for much the same end that the former council was summoned. 3. The council of Ephesus, convened by Theodosius the Younger, at the suit of Nestorius. 4. The council of Chalcedon, held in the reign of Martianus, which approved of the Eutychian heresy. 5. The second council of Constantinople, assembled by the emperor Justinian, condemned the three chapters taken out of the books of Theodorus of Mopsuestia, having first decided that it was lawful to anathematize the dead. Some authors tell us, that they likewise condemned the several errors of Origen about the Trinity, the plurality of worlds, and the pre-existence of souls. 6. The third council of Constantinople, held by

the command of Constantine Pogonatus the emperor, in which they received the definitions of the five first general councils, and particularly that against Origen and Theodorus of Mopsuestia. 7. The second Nicene council. 8. The fourth council of Constantinople, assembled when Lewis II. was emperor of the west. The regulations which they made are contained in twenty-seven canons, the heads of which are set down by Mr. Du Pin, to whom the reader is referred.

Provincial COUNCIL, an assembly of prelates of a province under the metropolitan.

COUNSELLOR, in general, a person who advises another: thus we say, a counsellor at law, a privy counsellor, &c.

COUNSELLOR at Law, a person retained by a client to plead his cause in a public court of judicature.

COUNT, *Comes*, a nobleman who possesses a domain erected into a county. The dignity is a medium between that of a duke and a baron. See *EARL*.

COUNT, in law, signifies the original declaration in a real action, as a declaration is in a personal one.

COUNT-WHEEL, in the striking part of a clock, a wheel which moves round once in twelve or twenty-four hours. It is sometimes called the locking-wheel. See the article *CLOCK*.

COUNTER, a term which enters into the composition of divers words of our language, and generally implies opposition; but when applied to deeds, means an exact copy kept by the contrary party, and sometimes signed by both parties.

COUNTER, in naval architecture, an inward arching under the ship's stern, to which it is parallel: the upper-part of it is terminated by the bottom of the stern, and the lower-part by the buttock. See *STERN* and *BUTTOCK*.

COUNTER-APPROACHES, in fortification, lines and trenches made by the besieged, in order to attack the works of the besiegers, or to hinder their approaches.

Line of COUNTER-APPROACH, a trench which the besieged make from their covert-way to the right and left of the attacks, in order to scour the enemies' works. This line must be perfectly enfiladed from the covert-way and the half moon, that it may be of no service to the enemy, in case he get possession of it.

COUNTER-BARRY, or *CONTRE-BARRE*, in heraldry, is the same as our bendy sinister per bend counterchanged. See the article *BARRY*.

COUNTER-BATTERY is a battery raised to play upon another to dismount the guns. See the article *BATTERY*.

COUNTER-BOND, a bond of indemnification given to one who has given his bond as a security for another's payment of a debt, or the faithful discharge of his office or trust.

COUNTER-BRACING, in the marine. See this operation fully explained in the article *TACKLING*.

COUNTER-CHANGED, in heraldry, is when any field or charge is divided or parted by any line or lines of partition, consisting all interchangeably of the same tinctures.

COUNTER-CHARGE, a reciprocal charge or recrimination brought against an accuser.

COUNTER-CHEVRONED, a field chevrony, parted by one or more partition lines.

COUNTER-COMPOSED, in heraldry, is when the figure is composed of two panes.

COUNTER-DEED, a secret writing, either before a notary or under a private seal, which destroys, invalidates, or alters a public one.

COUNTER-DRAWING, in painting, is the copying a design, or painting, by means of a fine linen cloth, an oiled paper, or other transparent matter, where the strokes appearing through are followed with a pencil, with or without colour. Sometimes it is done on glass, and with frames or nets divided into squares with silk or with thread, and also by means of instruments invented for the purpose, as the parallelogram.

COUNTER-ERMINE, in heraldry, is the contrary to ermine, being a black field with white spots.

COUNTERFEIT-ARCHITECTURE. See the article *ARCHITECTURE*.

COUNTER-FISSURE. See the article *CONTRAFISSURE*.

COUNTER-FACED, or *CONTRE-FACE*, in heraldry, is the same that we call barry per pale counter-changed; but then the number of panes into which the field is divided, is always specified.

COUNTER-FOIL, or *COUNTER-STOCK*, in the exchequer, that part of a tally which is kept by an officer of the court. See the article *TALLY*.

COUNTER-FORTS, in fortification, certain pillars and parts of the walls, distant from fifteen to twenty feet from each other, which advance as much as may be in the ground, and join to the height of the cordon by vaults, to sustain the chemin de rondes, and part of the rampart, to fortify the wall, and strengthen the ground. See *FAUSSE-BRAY*.

COUNTER-FUGUE, in music, is when the fugues go contrary to one another. See the article *FUGUE*.

COUNTER-GUARD, or *ENVELOPE*, in fortification, a mound of earth raised sometimes in the ditch of a place, and sometimes beyond it, either in form of a simple parapet, or a small rampart, bordered with a parapet. They are designed to cover the faces and points of the bastions.

COUNTER-LIGHT, or *CONTRE-JOUR*, a light opposite to any thing, which makes it appear to disadvantage. A single counter-light is sufficient to take away all the beauty of a fine painting.

COUNTER-MARCH, in military affairs, a change of the face or wings of a battalion. The files counter-

counter-march to bring those which are in front to the rear; and the ranks counter-march, when the wings or flanks of a battalion change ground with each other.

COUNTER-MARCHING also signifies returning or marching back again.

COUNTER-MARK, a mark put upon goods that have been marked before. It is also used for the several marks put upon goods belonging to several persons, to shew that they must not be opened but in the presence of them all or their agents.

COUNTER-MINE, a well or hole sunk into the ground by the besieged, with a gallery or alley running from it to discover the enemy's mines, and prevent their effect.

COUNTER-MURE, a wall built close to another, that it may not receive any damage from the contiguous buildings.

COUNTER-PALED, *Contre-Pallé*, in heraldry, is when the escutcheon is divided into twelve pales parted per fesse, the two colours being counter-changed; so that the upper are of one colour, and the lower of another.

COUNTER-PART, in music, denotes one part to be applied to another. Thus the bass is said to be a counter-part to the treble. In law, it is the duplicate or copy of any indenture or deed.

COUNTER-PASSANT is when two lions are in a coat of arms, and the one seems to go quite the contrary way from the other.

COUNTER-PLEA, in law, a cross or contrary plea, particularly such as the demandant alleges against a tenant in courtesy or dower, who prays the king's aid, &c. for his defence.

COUNTER-POINT, in music, the art of composing harmony, or of disposing several parts in such a manner as to make an agreeable whole or a concert. In general, every harmonious composition, or composition of many parts, is called counter-point. It took its name from hence: before notes of different measures were invented, the manner of composing was to set pricks or points one against another, to denote the several concords.

COUNTER-POINTED, *Contre-Pointé*, in heraldry, is when two chevrons in one escutcheon meet in the points, the one rising as usual from the base, and the other inverted falling from the chief; so that they are counter to one another in the points. They may also be counter-pointed when they are founded upon the sides of the shield, and the points meet that way, called counterpointed in fesse.

COUNTERPOISE, in the manege, is the liberty of the action and feat of a horseman; so that in all the motions made by the horse, he does not incline his body more to one side than to the other, but continues in the middle of the saddle, being equally on his stirrups, in order to give the horse the proper and seasonable aids.

COUNTERPOISE is also a piece of metal called by some the pear, on account of its figure, and the mass, by reason of its weight, which sliding along the beam, determines the weight of bodies weighed by the *statera Romana*. See the article *BALANCE*.

COUNTER-POISON, an antidote or medicine which prevents the effects of poison. See the article *POISON*.

COUNTER-POTENT, *Contre-Potenté*, in heraldry, is reckoned a fur as well as vair and ermine, but composed of such pieces as represent the tops of crutches, called in French, *potences*, and in old English, *potents*.

COUNTER-PROOF, in rolling-press printing, a print taken off from another first printed; which, by being passed through the press, gives the figure of the former, but inverted. To counter-prove is also to pass a design in black lead, or red chalk, through the press, after having moistened with a sponge both that and the paper on which the counter-proof is to be taken.

COUNTER-QUARTERED, *Contre-ecartelé*, in heraldry, denotes the escutcheon, after being quartered, to have each quarter again divided into two.

COUNTER-ROLLS, are the rolls that sheriffs of counties have with the coroners of their proceedings, as well of appeals as of inquests.

COUNTER-ROUND, a body of officers going to inspect the rounds.

COUNTER-SALIENT is when two beasts are borne in a coat leaping from each other directly the contrary way.

COUNTER-SCARP, in fortification, the slope of the moat which faces the body of the place: but this word is frequently used for the glacis, and covered-way.

Angle of the COUNTER-SCARP, is that made by the two sides of the counter-scarp meeting before the middle of the curtain.

COUNTER-SIGNING, the signing, the writing of a superior in quality of secretary. Thus charters are signed by the king, and countersigned by a secretary of state or lord chancellor.

COUNTER-SWALLOW-TAIL, in fortification, an out-work in form of a single tenaille, wider at the gorge than the head.

COUNTER-TALLY, one of the two tallies upon which any thing is scored.

COUNTER-TENOR, called by the French, *haut-contre*, one of the middle parts of music opposite to the tenor. See the article *TENOR*.

COUNTER-TIME, in the manege, is the defence or resistance of a horse that interrupts his cadence, and the measure of his manege, occasioned either by a bad horseman, or by the malice of the horse.

COUNTER-TRENCH, in fortification, certain trenches thrown up by the garrison against the besiegers.

COUNTER-

COUNTER-TRIPPING, is when two beasts are borne in a coat in a walking posture, the head of the one being next the tail of the other.

COUNTER-WORKING, the raising of works to oppose those of the enemy.

COUNTNER is also the name of a counting-board in a shop, and of a piece of metal with a stamp on it, used in playing at cards.

COUNTER of a Horse, that part of a horse's forehead which lies between the shoulders and under the neck.

COUNTRY, among geographers, is used indifferently to denote either a kingdom, province, or lesser district. But its most frequent use is in contradistinction to town: thus it is said, that such a man went down into the country.

Among miners, the term **countries** is an appellation given to the works under ground. See the article **MINE**.

COUNTY, in geography, originally signified the territory of a count or earl; but now it is used in the same sense with shire.

COUNTY-CORPORATE, a title given to several cities on which the English monarchs have thought proper to bestow extraordinary privileges, annexing to them a particular territory of land, or jurisdiction, as the county of Middlesex annexed to the city of London, the county of the city of York, &c.

COUNTY-COURT, a court of justice, held every month in each county, by the sheriff or his deputy.

This court has the determination of debts and trespasses under forty shillings.

COUPED, *Coupe*, in heraldry, is used to express the head, or any limb, of an animal, cut off from the trunk, smooth; distinguishing it from that which is called *erazed*, that is, forcibly torn off, and therefore is ragged and uneven.

COUPED is also used to signify such crosses, bars, bends, chevrons, &c. as do not touch the sides of the escutcheon, but are, as it were, cut off from them.

COUPLET, a division of a hymn, ode, song, &c. wherein an equal number, or equal measure, of verses is found in each part, which division, in odes, are called strophes. See the article **STROPHE**.

Couplet, by an abuse of the word, is frequently made to signify a couple of verses.

COURANT, or **CURRENT**, in a general sense, expresses the present time, as we say, the year 1765 is the current year; the first of this current month, that is, this present year and month.

COURANT, in a commercial sense, any thing that has a course, or is received in commerce; as the courant coin, &c. also the ordinary and known price of goods, &c. in which sense we say, the price courant.

COURIER, a messenger sent post, or express, to carry dispatches.

COURSE, or way of a ship, in navigation, is the point of the compass on which the ship moves; or rather, the angle which the course or track of the ship makes with the meridian. Now the nearest way between any two places on the globe will be the arc of a great circle, and therefore, were this method of sailing, commonly called *great circle sailing*, as easy and convenient in the calculation as the others are, it would certainly be the best; but since the arc of a great circle makes a different angle with every meridian it passes over, that is, the angle of the ship's course is continually varying, there can be no constant practical rule for her conduct deduced from this method. This difficulty, not only in this, but in every other method of navigation formerly known, made it necessary to look out for some method by which the ship's course could be regulated in such a manner as at all times to make equal angles with the meridian, and this was happily effected in the invention of the compass: for by the property of magnetism, the needle will in every place make a given angle with the meridian, if the ship be steered on a given point of the compass, and therefore the ship must cross every meridian under equal angles while the needle remains in the same position with respect to the meridian, and as the needle cannot change its position, without being observed by the navigator, he may at all times, when he finds that to be the case, easily regulate the course of the ship, so as to bring the needle to its former position, or allow for the quantity of its variation, as the exigence of the case may require.

The line thus described by the ship, sailing in the manner above-described, is called a **RHUMB-LINE**, for the particular properties of which see that article.

COURSE, in architecture, a continued range of stones, level, or of the same height throughout the whole length of the building, without being interrupted by any aperture.

COURSE of Plinths, the continuity of a plinth of stone, or plaster, in the face of a building, to mark the separation of the stones.

COURSE is also applied for the time spent in learning the elements of a science; as a student is said to go through his courses of philosophy, divinity, mathematics, &c. at the university.

COURT, *Curia*, in a law sense, the place where judges distribute justice, or exercise jurisdiction: also the assembly of judges, jury, &c. in that place.

COURT-BARON, a court that every lord of a manor has within his own precincts.

COURT of Chivalry, or the **Marshal's COURT**, that whereof the judges are the lord high constable, and the earl marshal of England.

COURT of Conscience, a court in the cities of London, Westminster, and some other places, that determines matters in all cases, where the debt or damage is under forty shillings.

COURT of Delegates, a court where delegates are appointed by the king's commission, under the great seal, upon an appeal to him from the sentence of an archbishop, &c. in ecclesiastical causes; or of the court of admiralty in any marine cause.

COURT-LEET, a court ordained for the punishment of offences under high-treason against the crown.

COURT-MARTIAL, a court appointed for the punishing offences in officers, soldiers, and sailors, the powers of which is regulated by the mutiny bill.

COURT of Requests, was a court of equity, of the same nature with the chancery, but inferior to it. It was chiefly instituted for the relief of such petitioners as in conſcionable cases addreſſed themſelves to his majeſty: the lord privy-ſeal was chief judge of this court.

COURT is alſo an appendage to a houſe or habitation, conſiſting of a piece of ground, incloſed with walls, but open at top.

COURT is alſo uſed for the palace or place where a king or ſovereign prince reſides.

COURTESY, or **CURTESY of England**, a certain tenure, whereby a man marrying an heiress ſeized of lands of fee ſimple, or fee tail general, or ſeized as heir of the tail ſpecial, and getteth a child by her that cometh alive into the world, though both it and his wife die forthwith; yet if ſhe were in poſſeſſion, he ſhall keep the land during his life, and is called *tenant per legem Angliæ*, or tenant by the curtesy of England; becauſe this privilege is not allowed in any country except Scotland, where it is called *curialitas Scotiæ*.

COUSIN, a term of relation between the children of brothers and ſiſters, who in the firſt generation are called couſin-germans, in the ſecond generation, ſecond couſins, &c. If ſprung from the relations of the father's ſide, they are denominated paternal couſins; if on the mother's, maternal.

COUSINET, in architecture, the ſtone that crowns a piedroit, or pier, the under ſide of which is level, and the upper curved to receive the firſt ſpring of an arch or vault. It is alſo the face on the ſide of the volutes in the Ionic capital, which the French artiſts call *baluſtre* and *orieller*.

COUSU, in heraldry, ſignifies a piece of another colour or metal placed on the ordinary, as if it were ſewed on, as the word imports. This is generally of colour upon colour, or metal upon metal, contrary to the general rule of heraldry.

COVERT, in heraldry, denotes ſomething like a piece of hanging, or a pavilion falling over the

top of a chief or other ordinary, ſo as not to hide but only to be a covering to it.

COW, in zoology, the female of the ox kind. See the articles **BOS** and **OX**.

COW-ITCH, in botany, the Engliſh name of the hairy *phaecolus*. See **PHASEOLUS**.

COW'S-LIP, *Primula Veris*, in botany. See the article **PRIMULA**.

COWARD, in heraldry, a term given to a lion borne in an eſcutcheon with his tail doubled, or turned in between his legs.

COWL, or **COUL**, a habit worn by the Bernardines and Benedictines, of which there are two kinds, one white, very large, worn in ceremonies; the other black, worn on ordinary occasions in the ſtreets, &c.

COXENDIX, in anatomy, a general term for the hip. See the article **HIP**.

CRAB, in naval affairs, a ſort of wooden pillar let down through a ſhip's decks, having its lower end reſſing in a ſocket called a ſawcer; and in the upper end two or three holes above one another through the middle of it, into which long bars are let, whoſe length are nearly equal to the breadth of the deck. It is uſed to heave in the cable, or purchaſe any other weighty matter which requires a great mechanical power. This machine differs from a capſtern, in having no drum-head, and in having the bars to go entirely through it, and reach from one ſide of the deck to the other; whereas thoſe of the capſtern are more in number, and only reach about eight inches or a foot into the drum-head, according to their different ſizes. See the article **CAPSTERN**.

CRAB'S CLAWS, *Chela Cancrorum*, in the materia medica, are the tips of the claws of the common crab, broken off at the verge of the black part, ſo much of the extremity of the claws only being allowed to be uſed in medicine as is tinged with this colour. The blackneſs however is only ſuperficial: they are of a greyiſh white within, and when levigated, furniſh a tolerably white powder.

Crab's claws are of the number of the alkaline abſorbents, but they are ſuperior to the generality of them in ſome degree, as they are found on a chemical analyſis to contain a volatile urinous ſalt. They are always kept in the ſhops levigated to a fine powder, and are ſometimes preſcribed ſingly, though rarely, becauſe of their want of the beautiful white colour of ſome of the others. They are the baſis, however, of the famous Gaſcoigne-powder, the lapis contrayerva, and many other of the compound ſudorific powders.

CRAB'S EYES, *Oculi Cancrorum*, in pharmacy, are a ſtrong concretion in the head of the cray-fiſh. They are rounded on one ſide, and depreſſed and ſinuated on the other, conſiderably heavy, moderately hard, and without ſmell. We have them from Holland, Muſcovy, Poland, Denmark, Sweden,

den, and many other places, some of them probably taken out of the heads of the animals, but the far greatest part picked up on the shores of the Baltic, and of other seas and large rivers.

Crab's eyes are much used both in the shop medicines and extemporaneous prescriptions, being accounted not only absorbent and drying, but also discutient and diuretic.

CRAB-TREE, in botany, a species of the malus or apple; the fruit is less than most apples, and is extremely acid and astringent: its chief use is for making verjuice.

CRADLE, a well known machine, in which infants are rocked to sleep.

It denotes also that part of the stock of a cross-bow where the bullet is put.

CRADLE, in surgery, a case in which a broken leg is laid after being set.

CRAMBE, wild sea-cabbage, in botany, a genus of plants, the flower of which is tetrapetalous and cruciform: the fruit is a roundish capsule, with one cell and two valves, containing a single roundish seed. This plant is used as an aliment like other cabbage, when very young, but is esteemed more hot and dry. Dale tells us, the leaves heal wounds, and disperse inflammations and other tumours.

CRAMP, in medicine, a convulsive contraction of a muscular part of the body, being either natural, as in convulsive constitutions; or accidental, from living in cold places, under ground, &c. It affects all parts indifferently, but the hams, calves, feet, and toes, oftener than the arms and hands: it is seldom mortal, though its returns are often, quick, and continuance long, with great pain and distension of some vessels, as appears from the knots and ganglions it occasions. If it be natural, observe the cure as in an epilepsy or convulsions; if accidental, it is removed by rubbing the part affected.

CRAMP-FISH, the English name of the torpedo. See the article **TORPEDO**.

CRAMP-IRON, or **CRAMPS**, a piece of iron bent at each end, which serves to fasten together pieces of wood, stones, or other things.

CRAMPONEE, in heraldry, an epithet given to a cross, which has at each end a cramp or square piece coming from it; that from the arm in chief towards the sinister angle, that from the arm on that side downwards, that from the arm in base towards the dexter side, and that from the dexter arm upwards.

CRANE, in mechanics, is a machine of vast use in raising great weights, such as large stones, merchandises, timber, &c.

The crane is of two kinds, chiefly; the first of these, represented in Plate XXXIX. *fig. 1.* is fixed; except its gibbet BGV, which is moveable on its axis BG, in order to convey the burthen over the carriage, or whatever else is designed

to receive it. The second, generally called the rat's-tail crane, in which the whole crane, with its burthen, &c. turns round on the strong post S. *fig. 2.* But those are again constructed in different manners, according as their different situations or uses require; and often, according to the different degrees of skill or experience in the constructors. We shall give a brief description of both those forms, together with their several inconveniences, improvements, additions or alterations, as far as hath come to our knowledge.

When great weights are to be raised from a considerable depth, and laid on carriages very near the precipice, as for instance at the edge of a stone quarry, it must be a fixed one, and only the gibbet moveable. Thus let ACBEED *fig. 1.* represent a crane of this kind, A a Q the roof of the crane, to preserve the rope RTrr passing over the gibbet BGV from the weather, when the arm of the gibbet is brought under it, by being turned towards Y; AT the upper piece of the crane, called the plate, in an horizontal position, XYZ the three crane posts, braced at top and bottom, DS, MN, IE three cills within the stone-work, braced with wood, and made fast with an upright plate of iron pinned to the wood on each side. When the crane is not in stone-work, the three pieces, or cills, must be one continued piece, reaching from D to E, HI and bE are the braces of the main post of the crane, which come up above the level of the wharf LwB, and which are longer and stronger than the others. Here a cross piece, whose section is (G) keeps the main post from twisting; RO is the capstern, or shaft of the crane on which the rope or chain is wound, and turned by the handspikes bd, fd, and ed, the part being strengthened with iron hoops above and below the hole at d; it turns on an iron pivot at O, in a hole, in a piece whose section is F: pp are two pins which hold on a collar in which the upper part of the shaft turns; CTPQ, a strong piece or block, having three pulleys, one vertical and two horizontal ones, the rope turning over the first, and between the other two.

In this construction there are several inconveniences; the first is that when the weight is raised to the height required, the usual method of moving the arm of the gibbet toward W or w, is by means of a rope fastened thereto, called the guide rope, which a man is to pull in order to bring the weight over the place where it is to be lowered. Now, in performing of this, the main rope or chain, not continuing parallel to the arm of the gibbet, gives the weight a tendency towards that side to which it deviates; and sometimes so suddenly, that without care, and much force applied, if the weight be very great, the burthen will swing to or from the carriage, so as to break every thing in its way. To remedy this some fix an horizontal piece like

Fig. 2. Crane

Cubic Equation

Fig. 10.

a hand-spike in the upright shaft of the gibbet, a little above B, to turn it by, but in this case also, the force is so unequal as the weight is carried round, that the lives of the men, who are loading, depends entirely on the care of the man who guides the weight by either of those methods.

But if upon the axis of the gibbet there be fixed an iron wheel *y*, of several teeth, to be carried round by a pinion *u* of a few leaves, upon the end of whole axis, which passes through the perpendicular piece T X, behind the shaft of the gibbet there is fastened a wheel *x* with arms; a man standing at that wheel is out of the way, and has such an advantage of power as to hold the weight steady in any position whatsoever; its tendency to swing being not sensibly felt at the ends of the arms of the last wheel. The first who made use of this method was the late Ralph Allen, Esq; at his stone quarry at Bath, where the weight raised is four or five, and sometimes six or seven, tons.

The second sort, or that commonly called the rat's-tail crane, is represented by *fig. 2.* it moves round like a wind-mill on the post S, which is fixed standing upright by means of the braces and cills L L L L L L L L. F f is a brace and ladder serving for the same uses with the gibbet E N M F, pulls for the rope to run over and come to the weight at H, A C a wheel of a large diameter for two or three men to walk in; by which means the wheel is turned, and the rope R M N E D wound on the horizontal axis B b. But this is the very worst and most dangerous method of working a crane; instead of which the horizontal axis B b is now oftener carried round by a strong wheel and pinion P C A *fig. 3.* by means of the two winches *a* and *b*; at the other end of the axis is sometimes fixed a wheel with teeth, and a catch K, to hold the burthen to the height it is brought up to, while the crane is turned round in order to lower the burthen into the vessels, which is done by lifting up the catch, and being ready to let it down as need may require; but this, not to mention the sudden jerk this method must give to the whole machine, and thereby, when the weight is very considerable, run the risk of tearing it all to pieces; it is liable to be forgot through carelessness, or for want of presence of mind, when any great danger is apprehended.

Another method of stopping this crane is by means of a smooth wheel of wood, as W *n* instead of the toothed one; against which a semi-circumference of wood D I I B is held hard by means of the lever G F moving on the center L, and the ropes H G and F B while the weight is descending; but as in this case likewise, if the man at the crane be careless, very bad accidents may happen, Mr. Padmore made such a contrivance that the pall or lever, by which the axle is pressed to regulate the descending motion, communicates with the catch

above-mentioned in such manner, that if the man who ought to manage it, should carelessly let it go, the catch always takes, and by that means all accidents are prevented. This invention is as follows:

PP and pp *fig. 4.* represent two upright pieces fixed, in the most convenient manner, to the frame of the crane, so as to carry the three centers L K and *k*; when the main rope or chain R r Z, going over the pulley at *r*, or any where else, draws from the axle in the direction R r, the catch, if the end is at A, keeps it immovable; but by pulling at H, the lever G F rises at F, and consequently draws up the end B of the pall B D, which moving on the center *k*, does by its end D, by means of the bar D E, pull down E, and raise the end A of the catch, so as to let the weight run down; but to prevent its running too fast, one must pull a little harder, which it is evident from the figure, will cause the semi-circumference I O I to press against the wheel, and thereby slacken the descent of the weight, and if it is pulled very hard will entirely stop it. Now if the person holding at H, should, through, carelessness or otherwise, let it go, the weight Q in descending, will bring down the pall at B, and raise its other end, so as to throw the catch upon the teeth of the ratchet, and thereby stop the whole motion without accident.

But after all, where weights are to be raised or lowered a great way, as in loading or unloading vessels into, or out of high warehouses, and where the weight exceeds not two or three tons, and many hands not to be had, let a worm, or endless screw, turned by a handle at each end, be applied to the teeth of the wheel C A (*fig. 3.*) instead of the pinion P, but whose axis is placed at right angles to the axis of the pinion. This will be found to answer all the other contrivances, and be vastly more simple and commodious: for the teeth of the wheel are pulled by the weight so directly against the thread of the screw, that one may leave it in any position whatsoever, without any catch or danger of the weight running down.

But then if you would have the weight to descend pretty quick, which cannot be performed by applying the hand to the winch, it moving through a large space in comparison to the weight, and without which, sufficient force will be wanting, only give the winch a swing, and if the worm be well oiled, the two handles will perform the office of the fly of a jack, turning round very fast, and at the same time regulating the motion of the weight; and if at any time you want to stop it intirely, it will be sufficient to grasp the axis of the screw in the hand, which may by this means be stopped in two or three turns of the winch.

CRANE'S BILL, among surgeons, a kind of forceps, so called from its figure.

CRANE'S BILL, in botany, the English name for the geranium. See the article GERANIUM.

CRANIOIARIA, in botany, a genus of plants whose flower consists of one unequal petal, and contains four stamina. The pericarpium is coriaceous, ovated, acute on both sides, and bivalvular.

The fruit is a woody depressed nut, acuminate on both sides, and marked with dentated furrows.

CRANK, a contrivance in machines, in manner of an elbow, only of a square form, projecting from a spindle, and serving by its rotation to raise and fall the pistons of engines.

CRANK likewise denotes the iron support for a lantern, or the like : also the iron made fast to a stock of a bell for ringing it.

CRANNY, in glass-making, an iron instrument, wherewith the necks of glasses are formed.

CRAPPE, in commerce, a kind of stuff, made in the manner of gauze, with raw silk, gummed and twisted in the mill.

CRASIS, among physicians, is used to signify such a due mixture of qualities in a human body, as constitutes a state of health.

CRASIS, in grammar, the contraction of two letters into one long one, or a diphthong. Thus *αλφεια* is contracted into *αλφει*.

CRASSAMENTUM, in physic, the thick red, or fibrous part of the blood, otherwise called cruor, in contradistinction to the serum, or aqueous part. See **BLOOD**.

CRASSULLA, in botany, a genus of plants, whose flower consists of five narrow petals, with long, linear, straight, connivent ungues; and five tubulated stamina.

The fruit is composed of five oblong, acuminate, straight, compressed capsules, opening longitudinally inwards, and filled with a number of small seeds.

CRATÆGUS, wild-service, in botany, a genus of plants, the flower of which consists of five roundish concave petals, inserted into the cup with many stamina.

The fruit is a roundish, fleshy, umbilicated berry, containing two hard oblong seeds.

The common wild-service grows to the size of a pear-tree, and the trunk is covered with a whitish smooth bark, but the young branches are covered with a brownish red. The leaves are placed alternately, and stand on pretty long foot-stalks; these are cut into many acute angles, with several small indentures on their edges; the flowers are white, and produced in large bunches towards the extremities of the branches; the fruit is like those of the hawthorn, of a brownish colour, and if kept some time has a tartish agreeable flavour.

They are reckoned good in all kinds of fluxes.

The wood is hard and white, and is useful for many purposes; but particularly to mill-wrights.

CRATCHES, in the manege, a swelling on the pastern, under the fetlock, and sometimes under the hoof; for which reason it is distinguished into

the *finew cratches*, which affect the *finew*, and those upon the *cronet*, called *quitter-bones*.

CRATICULA, a kind of grid-iron, or chemical instrument, made of square pieces of iron, of the thickness of one's finger, placed in acute angles, about half a finger's space distant from one another. It serves in making fires to keep up the coals.

CRAY, a distemper in hawks, proceeding from long feeding upon cold stale meat.

CRAY-FISH, the English name of the larger long-tailed squillæ. See **SQUILLA**.

CRAYON, or **PASTIL**, among painters, implies a composition of colours, reduced to the texture of chalk; and used dry, in the form and manner of pencils, for painting on paper.

CREAM, the fat part of the milk that swims upon the surface. See **MILK**.

CREAM of Tartar, called also crystals of tartar, in pharmacy, a preparation of tartar made in the following manner:

Take any quantity of crude tartar, boil it in water, till the parts which are capable of solution be entirely dissolved; filter the liquor whilst hot thro' a flannel bag into an earthen pan, and evaporate till a pellicle appears, then set it in a cold place, and suffer it to stand quietly two or three days: afterwards decant the fluid, and the crystals will be found adhering to the pan: scrape them off, and evaporate the fluid as before, and set it again to crystallise, and repeat the operation till the crystals are formed. Cream of tartar is a gentle purge. It attenuates and resolves tough humours, and is good against obstructions of the viscera, and in cachectic complaints. It is also a good adjunct to chalybeate medicines.

CREAT, in the manege, an usher to a riding-master; or, a gentleman bred in the academy, with intent to make himself capable of teaching the art of riding the great horse.

CREATION, the producing something out of nothing, which strictly and properly is the effect of the power of God alone, all other creations being only transformations, or change of shape. Creation, say the schoolmen, from no pre-existing subject, may be understood in different senses. 1. That is said to be created out of no pre-existing matter, in the production of which no matter is employed; as an angel. 2. Although matter may be employed in the production of a thing, it may be so produced as that both its matter and form are caused by the same agent at the same time. In this manner were the heaven and the earth created, in the opinion of those who deny that God made the chaos. 3. Although matter may be the subject in producing a thing, yet that thing may not depend on matter either with respect to its future or present existence. Such is the human soul, for although it is created

in pre-existing matter, it is not created out of pre-existing matter, but of nothing, and therefore is no ways dependent on matter for existence. See the article **WORLD**.

Epocha of the CREATION. See the article **EPOCHÆA**.

CREATION, in the Romish church, the re-production of the humanity of Jesus Christ in the eucharist, by the words of the consecration.

CREDENTIALS, letters of recommendation, and power, especially such as are given to ambassadors, or public ministers, by the prince or state that sends them to foreign courts.

CREDIBILITY, a species or kind of evidence, less indeed than absolute certainty or demonstration, but greater than mere possibility: it is nearly allied to probability, and seems to be a mean between possibility and demonstration. See the article **EVIDENCE**.

CREDIT, in commerce, a mutual trust or loan of merchandize, or money, on the reputation of the probity and sufficiency of a dealer.

CREDITOR, a person to whom any sum of money is due, either by obligation, promise, or otherwise.

CREDITOR, in book-keeping. See the article **BOOK-KEEPING**.

CREED, a brief summary of the articles of a Christian's belief.

CREEK, the part of a haven where any thing is landed from the sea.

CREEPER, in ornithology, a name given to several species of *ispida*, otherwise called *certhia*, or *certhius*, and in English, the *ox-eye*.

CREEPER, in naval affairs, a small instrument of iron, having a shank and four hooks or claws, and something resembling a grappling. It is used to throw into the bottom of any river or harbour, with a rope fastened to it, to hook and draw up any thing from the bottom. See **GRAPPLING**.

CREMASTER, in anatomy, the name of a muscle of the testicle, of which there is one on each side.

It arises fleshy from the lowest and fore-part of the *os ilium*, and upper part of the *ligamentum pubis*: its fibres running parallel with those of the oblique ascendens, and almost encompassing the process of the *peritonæum*, descends with it, and is inserted into the *tunica vaginalis*, upon which it spreads in several distinct portions.

CRENATED, among botanists, is said of leaves, the edges of which are furnished with indentings, contiguous to each other, and neither inclining toward the point nor base. Of these some are acute, others obtuse, &c.

CRENELLE, or **IMBATTLED**, in heraldry, is used when any honourable ordinary is drawn, like the battlements on a wall to defend men from the enemies' shot.

CREPIS, in botany, a genus of plants, whose flower is compound, uniform, and imbricated; the proper flowers are monopetalous, ligulated, and indented at the top in five parts, each containing five short hairy filaments, topped with cylindraceous anthers. The seed is oblong, solitary, and crowned with long feathery down.

CREPUSCULUM, in astronomy, the same with twilight; by which is understood the time from the first appearance of the morning until sunrise, and from sun-setting until there be no remains of day.

The *crepusculum*, or twilight, is chiefly caused by the atmosphere surrounding the earth, which reflects back the light of the sun upon us so strongly, as totally to obscure the faint light of the stars, and thereby render them invisible: for were there no atmosphere involving the earth, no part of the heavens would appear to shine, but that in which the sun is placed; and a spectator, if he turned his back to the sun, would immediately perceive it as dark as night, and in the day-time, when the sun was shining in its utmost splendour, the least stars would be seen shining, as they do now in the night in every part of the heavens but that wherein the sun then was.

Moreover, if there were no atmosphere, the sun immediately before his setting, would shine as briskly as at noon; but in a moment, as soon as he is set, we should have the face of the earth in as great darkness as it would be at midnight: so quick a change, and so sudden a passing from the greatest light to the greatest darkness, would be very inconvenient to the inhabitants of the earth. But by means of the atmosphere it happens, that though after sun-setting we receive no direct light from the sun, yet we enjoy its reflected light for some time; so that the darkness of the night comes not suddenly, but by degrees. For after the earth by its revolution round its axis has withdrawn us from the sight of the sun; the atmosphere, which is higher than we are, will still be illuminated by the sun; so that for a while the whole heavens will have some of his light imparted to it. But as the sun goes still lower under the horizon, the less is the air illuminated by him: so that when he is got as far as 18 degrees below the horizon, he no longer enlightens our atmosphere, and then all that part thereof that is over us becomes dark.

So likewise in the morning, as soon as the sun comes within 18 degrees of the horizon, he begins again to enlighten the atmosphere, and to diffuse his light through the heavens: so that its brightness does still increase, till the sun rises and makes full day.

To make this plainer, imagine the circle **ADL** (Plate XXXIX. fig. 5.) on the surface of the earth, in the plane of the vertical circle in which the sun is when under the horizon. Let there likewise be

another

another concentric circle CBM in the same plane, including that portion of the air that reflects the sun's beams: and suppose the eye to be on the earth's surface at A, whose sensible horizon is AN. Since no line can be drawn to A between the tangent AN and the periphery AD, by the sixteenth of the Third book of Euclid's Elements, it is plain, that when the sun is under the horizon, no direct rays can come to the eye at A: but the sun being in the line CG, a line may be drawn from him to C, so that the particle C may be illuminated by the direct rays of the sun; which particles may reflect those rays to A, where they may enter the eye of the spectator: and by this means the beams of the sun's light illuminating an innumerable multitude of particles, may by them be reflected to the spectator in A. Let the tangent AB meet with the surface of the orb of air that reflects the light in B; and from B draw BD, touching the circle ADL in D, and let the sun be in the line BD at S: then the ray SB will be reflected into BA, and will enter the eye, because of the angle of incidence DBE being equal to the angle of reflection ABE: and that will be the first ray that reacheth the eye in the morning, and then the dawning begins; or the last which falls upon the eye at night, when the twilight ends. For when the sun goes lower down, the particles at B can be no longer illuminated.

The reflection of the atmosphere does not seem to be the only cause of the twilight; but there is an æthereal air or atmosphere likewise round the sun, which shines after the body of the sun is set: this orb of the sun's atmosphere rising sooner, and setting later than the sun itself, shines out at mornings and nights in a circular figure, it being a segment of the sun's atmosphere cut by the horizon; and its light is quite of another sort than that which is made by the reflection of our atmosphere. But the duration of the twilight that arises from the sun's atmosphere, is shorter much than that made by the reflection of the earth's atmosphere, which does not end till the sun comes to be 18 degrees below the horizon, or thereabouts. But there can be no certain bounds fixed for the beginnings and endings of the twilights; for their lengths depend on the quantity of matter in the air which is able to reflect light, and on the height of the atmosphere. In the winter the air being condensed by the cold is low; and on that account the twilights are sooner over. In the summer the air is rarified by heat, and therefore being higher remains longer illuminated by the sun, so that the twilights last the longer: also the duration of the twilight is shorter in the morning than at night. We generally reckon that the twilight begins or ends, when in the morning the stars of the sixth magnitude disappear, or in the evening when they first come to be seen; the light of the air before that rendering them invisible.

Ricciolus observed at Bonania, that the morning twilight about the time of equinoxes, lasted an hour and forty-seven minutes; but in the evening two hours, and did not end till the sun was twenty degrees under the horizon: but in summer, the morning twilight was three hours and forty minutes long; the evening twilight scarcely ended till midnight.

Hence if we have the time of the beginning of the twilight in the morning, or the end of it at night, we may find the height of the air that reflects the light; for then the twilight ends, when a ray of light from the sun touches the globe of the earth, and is by the highest air reflected to our eyes: for having the time, we can find the depression of the sun below the horizon, and from thence the height of the air. For let SB be a ray of light touching the earth, which is reflected by a particle of air in its highest region, in the horizontal line AB; the angle SBN is the measure of the depression of the sun below the horizon: and because AB is also a tangent, the angle AED at the center is equal to the angle SBN; and its half, that is, the angle AEB, is equal to half SBN or half the depression of the sun. Suppose the depression of the sun at the beginning or end of twilight be eighteen degrees; then the angle AEB will be nine degrees, which would be true, did the ray SB pass through the atmosphere without refraction: but because it is refracted and bent towards H, we must diminish the angle AEB by a quantity equal to the horizontal refraction, which is about half a degree: and therefore the true measure of the angle AEB is $8\frac{1}{2}$ degrees. Moreover, AE is to BH as the radius is to the excess of the secant of the angle AEB above the radius, that is, as 100000 is to 1110. Therefore if the semidiameter of the earth be in round numbers 4000 miles, BH the height of the atmosphere which reflects the sun's rays, will be about 44 miles; for as 100000 is to 1110, so is 4000 to 44.

In a right position of the sphere the twilights are quickly over; because the sun descends constantly nearly in a perpendicular; but in an oblique sphere they last longer, the sun descending obliquely; and the more oblique the sphere is, that is, the greater the latitude of the place is, so much longer last the twilights: so that all they who are in above forty-eight degrees latitude in the summer, near the solstices, have their atmosphere illuminated the whole night, and the twilight lasts till the sun-rising, without any complete darkness.

In a parallel sphere the twilight lasts for several months; so that the inhabitants have either the direct or reflect light of the sun for almost all the year.

If below the horizon you conceive a circle to be drawn parallel to the horizon, and at a distance from it equal to the depression of the sun at the end of the twilight: this lesser circle is called the circle

circle which terminates the twilights; for whenever the sun by its apparent diurnal motion reaches this parallel, the morning twilight begins, or the evening ends, in whatever parallel of the equator the sun is.

In Plate XXXIX. *fig. 6.* let HQO be the horizon, VaX the circle parallel to it terminating the twilight, the circle HZO the meridian, EQa the equator. It is manifest that the more oblique the equator is to the horizon, so much the greater are the arches of the equator and its parallels, intercepted between the horizon and the terminating circle VaX . The arches QR , da , Ce , Gh , Kl , are called the arches of the twilights, because they determine the duration: and as each arch has a bigger or less proportion to its circle, so will the twilight when the sun is in that parallel, be longer or shorter. In the circle bounding the crepuscles take any point a , through which passes a parallel to the equator da ; and though a imagine a great circle to be drawn as MaN , touching the circle of perpetual apparition: and since the horizon likewise touches the same circle, these two circles will make equal angles with the equator and its parallels; for the measure of each angle is the distance of the parallel from its great circle. So likewise all the arches of the equator, and its parallels between the horizon and the circle MaN are similar, by Prop. 13. Book II. Theodosius's Sphericks. This circle MaN (*fig. 7.*) will either cut the bounding circle VaX in two points, or touch it in one. Let it first cut it in two points a and b ; and therefore the arches of the parallels da , Gh are similar: wherefore when the sun by its diurnal motion describes these two parallels, the twilights are equal; but while he describes any intermediate parallel as Ce , the time of the twilight is shorter; for in this case Cm the arch of twilight is less than Ce , which is similar to the arch da or Gh , and Ce and da are described by the sun in equal times. But when the sun is in parallels that are at a greater distance from the equator than Gh , the twilights last longer; for the twilight arch lK is greater than qK , which described by the sun in the same time as the arch of the crepuscle Gh .

While the sun is in parallels that are towards the elevated pole, the twilights do constantly grow longer, according as those parallels approach the poles: for the twilight arch op is longer in being described QR , and YU the same way is longer than op . But if the sun describe the parallel St , it never will meet with the bounding circle, and then the twilight lasts the whole night long.

Hence arises a great difference between the increase of the twilight and its decrease, and the increase and decrease of days and nights. For while the sun moves from the beginning of π to the first of Capricorn, all that time the days constantly decrease, and the nights increase: but in the twilight

it is otherwise; for though the twilight and days are at the longest when the sun is in the first degree of π , and then they both decrease together; yet the times of twilight do not continually decrease till the sun comes to ν , but there is a certain point between π and ν , to which when the sun arrives, we have the shortest twilight. From thence the twilights will begin to increase again, and there will be one arch of twilight similar to that when the sun is in the equator, before he reaches ν : and if the sun should go farther south, even beyond the tropic, the twilights would still increase, although the days decreased. And although the days from the beginning of the sun's entry into ν do constantly increase, yet the twilights grow shorter till the sun comes to a point between ν and γ , in which again we have the shortest twilight: this appears plain by what we are here to demonstrate in the next place.

2dly, Let the circle MaN (*fig. 8.*) touch the bounding circle in one point, which suppose to be a , through which draw the parallel to the equator da ; I say that when the sun is in this parallel the twilight will be the shortest of all. For because the arches of the parallels intercepted between the horizon and the circle MaN are all similar, they will be described by the sun in equal times: but because the twilight arches ce and gh are greater than cm or gi , the sun will be longer in moving through the arch ce than cm , and through the arch gh than gi ; that is longer than in describing the arch da , which arch therefore is the shortest twilight.

The distance of that parallel from the equator in which is the shortest twilight, is thus investigated. Because the circle MaN and the horizon HO touch the same parallel, which is the circle of perpetual apparition, they will both be equally inclined to the equator: and therefore the angle anT of the equator, and the circle MaN , is equal to the angle FQd of the equator and the horizon. Thro' the zenith Z and the point a draw the verticle circle ZYa , cutting the equator in the point T . The spherical triangles anT , TQY , are mutually equiangular to each other, because the angles at a and Y are right; and we have shewed that the angles at Q and n are equal; also the angles at T are equal, being vertical to each other: these triangles then being equiangular, are also equilateral; and therefore Ta will lie equal to TY , or to half the distance of the bounding circle from the horizon: moreover, an is equal to Qd , by 13 Prop. book II. Theod. for FR and da are parallel, and therefore dQ is equal to QY .

In the spherical triangle TQY rectangular at Y , we have the side TY half the distance of the bounding circle from the horizon; as also the angle YQT equal to FQd , which measures the complement of the latitude of the place; wherefore

we can find QY , and Qd , which is equal to it. From the point d to the equator draw the circle of declination dF ; and in the spherical triangle dQF , we have dQ and the angle Q , by which we can find the arch dF , the declination of the parallel of the least twilight from the equator, which was to be found.

This problem might have been solved by one single analogy. For in the triangle TQY , the radius : tang. TY :: co-tang. Q : fin. QY , or to the fin. of dQ : but the fin. of Q : cosin. of Q :: rad. : co-tang. Q . Therefore by the rules of the fifth Element, the rad. multiplied by the fin. of Q , will be to the tang. of TY into the cosin. of Q , as the radius is to the fin. of Qd ; but in the right-angled triangle QdF , radius is to the sine of Qd as the sine of the angle Q to the sine dF ; wherefore rad. $\times$ sine Q will be to the tang. of $TY \times$ co-sine of Q , as the sine of Q to sine of dF ; and thence, *ex æquo*, it will be as radius to tang. of TY , so co-sine of Q , or the sine of the latitude to the sine of the distance of the parallel from the equator. Having the declination of the sun, the time of the beginning of the morning twilight, which we call break of day, or the end of the evening twilight is thus to be found. Let op be the parallel of the sun meeting with the bounding circle in p ; and draw through the pole the circle of declination Pp . In the spherical triangle PZp we have all the sides for ZP is the complement of the latitude, Pp the complement of the sun's declination, and Zp equal to the sum of a quadrant, and the distance of the bounding circle from the horizon = $ZI + Ip$. From which we can find the angle ZPp , and its complement to two rights pPV : and the arch of the equator measuring this angle being converted into time, will shew the beginning or end of twilight.

CRESCENT, *Crescent*, the new moon, which, as it begins to recede from the sun, shews a little rim of light, terminating in points, called horns, that are still increasing, till it is in opposition to the sun, at which time it is full moon, or quite round.

CRESCENT, in heraldry, a bearing in form of a new moon.

CRESCENT is also an order of knights, instituted by Renatus of Anjou, king of Sicily, about the year 1448, so called from the badge of this order, which was an enamelled crescent of gold.

CRESCENT, a term among farriers. Thus a horse is said to have crescents, when that part of the coffin bone which is most advanced falls down and presses the sole outwards, and the middle of his hoof above shrinks, and becomes flat, by reason of the hollowiness beneath it.

CRESCENTIA, in botany, the calabash-tree. This plant grows naturally in the West-Indian islands: it rises to the height of twenty or thirty feet, with several knots upon the stem, dividing at

the top in many branches, which spread, and form a regular head. These are furnished with leaves, which come out irregularly; and are about six inches long, oval, and acuminate; of a livid green colour, with very short foot-stalks.

The flowers are produced from the sides of the branches, standing upon long foot-stalks. The calyx is short, monophyllous, and deeply divided into two obtuse segments. The corolla is monopetalous, and irregular, having a gibbous tube. The limb is reflexed, and divided into five segments: these are of a greenish yellow colour, striped and spotted with brown. The stamina consists of four slender filaments, two of which are the length of the corolla, and the other much shorter: these are terminated by double oblong antheræ.

The fruit is a large shell, either spherical, oval, or bottle-shaped, and incloses a number of flat cordated seeds.

These shells are large enough to contain three pints or two quarts of liquid; they are therefore made use of by the inhabitants of the islands for drinking-cups, after being cleaned of their pulp, the outer skin taken off, and dried: some of them are tipped with silver. They are also made use of for divers other purposes.

The leaves and branches of this tree are also eaten by the cattle in times when other provender are scarce, and the wood is hard and smooth, so is frequently used for making saddles, stools, and furniture.

Another species of *crescenia* is found in Campeachy, which rises not so high as the former, and the leaves, flowers, and fruit, are considerably less.

CRESS, or *Garden Cresses*, in botany. See the article **NASTURTIUM**.

Indian Cress. See **TROPÆOLUM**.

Scitica Cress. See **IBERIS**.

Water Cress. See **SISYMBRIUM**.

Winter Cress. See **ERYSIMUM**.

CREST, in armoury, the top part of the armour for the head, mounting over the helmet, in manner of a comb, or tuft of a cock, deriving its name from *crisla*, a cock's comb.

CREST, in heraldry, the uppermost part of an armoury, or that part of the cask or helmet next to the mantle.

CREST, among carvers, an imagery, or carved work, to adorn the head, or top of any thing, like our modern corniche.

CREST-FALLEN, a fault of an horse, when the upper part of his neck, called the crest, hangs to one side: this they cure by placing it upright, clipping away the spare skin, and applying plasters to keep it in a proper position.

CRETA, chalk, in natural history. See the article **CHALK**.

CREUX, a French term used among artists, and literally signifies a hollow cavity, or pit, out of which some-

something has been scooped or dug: whence it is used to signify that kind of sculpture, where the lines and figures are cut and formed within the face or plan of the plate, or matter engraved; and thus it stands in opposition to relieve, where the lines and figures are embossed, and rise prominent above the face of the matter engraved on.

CRIB, a frame of wood, wherein moist things, particularly salt, as it is taken out of the boiling-pan, are put to drain.

CRIBRATION, in pharmacy, the passing any substance through a sieve, or searce, in order to separate the finer particles from the grosser, whether the body be dry and reduced to powder, or moist, as the pulps of seeds, fruits, or roots.

CRIBROSUM Os, in anatomy, called also os ethmoides, and os cribriforme, a bone situated internally in the fore-part of the basis of the skull. The uses of it are to be a principal part of the organ of smelling, and to give a very great extent to the pituitary membrane in a small compass.

CRIC, a machine, otherwise called a jack. See the article **JACK**.

CRICK, among farriers, is when a horse cannot turn his neck any manner of way, but holds it fore-right, inasmuch that he cannot take his food from the ground without great pain. The cure is to thrust a sharp hot iron through the flesh of the neck in several places, at three inches distance, and rowel all of them with horse hair, flax, or hemp, anointing the rowels with hog's grease.

CRICKET, in zoology, the English name of the gryllus. See **GRYLLUS**.

Mole-CRICKET, the same with the gryllotalpa. See the article **GRYLLOTALPA**.

CRICOARYTANOIDEUS, in anatomy, a name given to two muscles of the larynx, called the cricoarytænoides posticum, and the lateral cricoarytænoides. They serve to dilate the glottis.

CRICOIDES, in anatomy, a cartilage of the larynx, called also the annular cartilage. It occupies the lowest part by way of base to the rest of the cartilages; and to the lower part of it the aspera arteria adheres.

CRICOTHYROIDÆUS, in anatomy, one of the five proper muscles of the larynx, which arise and terminate in it. It serves occasionally either to dilate, or constrict the glottis.

CRINGLE, in naval affairs, a small hole made in the bolt-rope of a sail, by intertwisting one of the divisions of a rope called a strand, alternately round itself, and then through the bolt-rope till it becomes three-fold: the use of a cringle is to fasten the ropes to, which gather up a sail to the yard, when it is to be reefed or furled. See **BRAIL**, **FURL**, and **REEF**.

CRIME, *Crimen*, the transgression of a law, either natural or divine, civil or ecclesiastic.

CRIMINOIDES, or **CRIMOIDES**, among phy-

sicians, a term sometimes used for the sediment of urine, resembling bran.

CRIMSON, one of the seven red colours of the dyes. See the article **COLOUR**.

CRINONES, among physicians, small worms that breed in the skin, called also dracunculi. See the article **DRACUNCULI**.

CRINUM, lilly-asphodel, in botany, a genus of plants, the flower of which is infundibuliform and monopetalous: it contains six tubulated filaments, topped with oblong, linear, incumbent antheræ.

The fruit is a subovated capsule, with three cells, each containing one or two oval seeds.

CRISIS, in medicine, is used in different senses, both by the ancient and modern physicians. With some it means frequently no more than the excretion of any noxious substance from the body. Others take the word for a secretion of the noxious humours made in a fever. Others use it for the critical motion itself; and Galen defines a crisis in fevers, a sudden and instantaneous change, either for the better or the worse, productive of recovery or death. The doctrine of crises is very obscure; however, the following are reckoned the principal symptoms of an approaching crisis, a sudden stupor, drowsiness, waking, delirium, anxiety, dyspnoea, grief, redness, titillation, nausea, heat, thirst, &c. after digestion, and about the critical time; and the symptoms and effects of a present crisis are after the preceding ones, and vomiting, looseness, thick sediment in the urine, bleeding at the nose, hæmorrhoids, sweat, abscesses, pustules, tumours, buboes, &c.

CRISP LEAF, among botanists, is when the circumference of the leaf grows larger than the disk will admit of, so that the surface is undulated, or raised in waves.

It is likewise called a curled leaf.

CRISTA GALLI, in anatomy, a process of the os ethmoides, making the upper-part of the septum narium. It takes its name from the supposed resemblance to the comb of a cock.

CRITHE, in surgery, commonly called the style, is a tubercle that grows in different parts of the eyelids. When it is small it comes only on the edge of the eye-lids, or very near it, between the cilia; but when it is large it spreads towards the middle of the lid. The cure of this disease must be varied, according as the crithe is attended with an inflammation, or is hardened and concentered.

CRITHMUM, samphire, in botany, a plant which grows on the rocks of the sea-side in many parts of England. The root is composed of many strong fibres, which strike deep in the crevices of the rocks. The stalks, which are fleshy and succulent, rise about two feet high, and are furnished with winged leaves.

The flowers are produced in circular umbels at the top of the stalks. These are of a yellow colour;

four; and are composed of five ovated, inflexed petals, with five stamina, which are succeeded by two elliptical compressed seeds, striated on one side.

Sampshire is recommended in medicine against obstructions of the viscera and urinary passages; but is more used as a pickle: it is very agreeable to the palate, creates an appetite, and is comfortable to the stomach.

Another species of crithmum grows naturally on the Pyrenean mountains, which is classed by Tournefort among the parsleys.

CRITICAL DAYS and SYMPTOMS, among physicians, are certain days and symptoms in the course of acute diseases, which indicate the patient's state, and determine him either to recover or grow worse. A careful observation of these days is of the greatest use towards the cure of diseases, lest mischief be done by unseasonable assistance from art, as when a physician endeavours to expel that which is not prepared to be evacuated, or else hinder the evacuation of such humours, as being subdued and concealed, endeavour to escape by some convenient outlet. According as the violence of the disease is more swift or slow, the critical days will be more or less distant from each other: thus in fevers which do not exceed the space of three weeks, the quaternary or septenary days are critical; and besides these, there are in the two first weeks many more incidentally critical days, as the third, fifth, sixth, &c. but if an acute disease extends itself beyond three weeks, then the quaternary days no more take place as critical, but only the septenary days are so, though the efficacy of these last is likewise abolished after the fortieth day. See the article **CRISIS**.

CRITICISM, the art of judging with propriety concerning any discourse or writing. Though the use of the word is ordinarily restrained to literary criticism, we may distinguish divers other branches of this art; as 1. Philolophical criticism, the art of judging of the hypotheses and opinions of philosophers. 2. Theological criticism, the art of judging of explications of doctrines of faith. 3. Political criticism, the art of judging of the means of governing, acquiring, and preserving states. 4. Grammatical criticism, the art of interpreting the words of an author, &c. Lord Bacon divides criticism, 1. As it regards the exact correcting and publishing of approved authors, by which the honour of such authors is preserved, and the necessary assistance afforded to the reader; yet the misapplied labours and industry of some have in this respect proved highly prejudicial to learning; for many critics have a way, when they fall upon any thing they do not understand, of immediately supposing a fault in the copy; and hence it happens that the most corrected copies are often the least corrected. 2. As it respects the explanation and illustration of authors by notes, comments, collections, &c. But here an ill

custom has prevailed, of skipping over the obscure passages, and expatiating upon such as are sufficiently clear; as if the design was not so much to illustrate the author, as to take all occasions of shewing their own learning and reading. It were therefore to be wished, says the noble author, that every original writer who treats an obscure subject, would add his own explanation to his work, and thus prevent any wrong interpretation by the notes of others. 3. There belongs to criticism a certain concise judgment or censure of authors published, and a comparison of them with other writers who have treated the same subject: in short, the art of criticism, though reckoned by some as a distinct part of philosophy, is in truth nothing else than a more correct and accurate knowledge in the other parts of it; and a readiness to apply that knowledge upon all occasions, in order to judge well of what relates to these subjects, to explain what is obscure in authors, to supply what is defective, and amend what is erroneous in manuscripts or ancient copies, to correct the mistakes of authors and editors in the sense of the words, to reconcile the controversies of the learned, and by these means to spread a juster knowledge of the beautiful passages and solid reasoning of authors, among the inquisitive part of mankind.

CRIZZELING is said of glass, which, by reason of too great a proportion of nitre, tartar, or borax, is scabrous or rough on the surface.

CROCHES, among hunters, the little buds growing about the tops of a deer or hart's horns.

CROCI, among botanists, the same with antheræ. See **ANTHERÆ**.

CROCODILE, *Crocodilus*, in zoology, a species of lizard, with a two-edged tail and triangular feet, the fore ones having five, and the hinder only four toes.

This animal is the largest of the lizard kind, growing to twenty-five feet in length, and about the thickness of a man's body. It is a native of the torrid zone, frequently found in salt-water rivers, where it lies concealed among the reeds or rushes, till it finds an opportunity to seize men or other animals, which it drags into the water, always taking this method of drowning them first, that it may afterwards devour them without resistance: its general food, however, is fish. The Africans and Indians eat its flesh, which is white, and of a kind of perfumed flavour.

CROCUS, saffron, in botany, a genus of plants whose characters are, it hath a perennial bulbous root, with narrow gramineous leaves, which are annual.

The flower arises immediately from the root, and consists of one petal; the tube of which is long, and the border is cut into six oblong, erect, equal segments: it hath three subulated filaments, shorter than the corolla, which are terminated with
arrow-

arrow-shaped anthers. The germen is placed at the bottom of the tube, and supports a filiform style, crowned with three convoluted, serrated stigmas.

The fruit is a roundish trilobular capsule, opening with three valves, and containing a number of roundish seeds.

There are many varieties of crocus, some of which blows early in the spring, and others in autumn; but it is from the autumnal crocus that well-known drug called saffron is taken.

The flower is of a beautiful purplish blue colour.

This species is cultivated in divers places; but is no where raised with so much success as in England. The usual way of propagating it is by the bulbs, of which it annually produces new ones. They are planted out in July in trenches, at three or four inches distance each way, and about the same depth. The off-sets produce only leaves the first year; but in September or October, the year following, they flower. As soon as the flowers open they are gathered, and the upper-part of the pistil or style is carefully separated from the rest, and reserved: This being the saffron, the other parts of the flower is thrown away as useless; the saffron is afterwards dried on a kiln built for the purpose, pressed into cakes, and is then fit for use.

Saffron is somewhat moderately heavy, very easily cut, of an acrid, penetrating, diffusive smell, somewhat affecting the head; but not unpleasant. The taste of it is hot, bitterish, and highly cordial: thrown into water, it almost instantaneously gives a strong, yellow, or redish colour, according to the quantity used.

Saffron should be chosen fresh, tough, flexible, of a strong smell, and of a high fiery colour; the same within side the cake as without.

It is in many places in great esteem in sauces, and on many occasions in foods; but its great use is in medicine, and indeed with us its sole use. It is a high cordial, and a very powerful aperient, detergent, and resolvent. It is almost of immediate relief against faintings and palpitations of the heart: it also strengthens the stomach, and assists digestion. It is of great use in disorders of the breast, arising from the lungs being loaded with a tough phlegm; and it softens the irritating acrimony of a vitiated serum on those parts, and by this means is often of great use against inveterate coughs. It opens obstructions of the viscera, and particularly in the liver. It cures jaundices, and promotes the menses. It is also anodyne; and occasionally serves as a pargoric.

The dose is commonly from two or three grains to ten or twelve; but we are told of much greater quantities given by many people; however, the use of it ought to be moderate and seasonable; for when the dose is too large, it produces a heaviness

of the head, and a sleepiness; and some have fallen into an immoderate, convulsive laughter, which ended with death.

CROCUS, in chemistry, denotes any metal calcined to a red or deep yellow colour: thus we meet with crocus martis aperiens and astringens, or the aperient and astringent crocuses of iron; also with the crocus veneris, or copper calcined to such a reddish powder.

CROCUS METALLORUM, an emetic preparation of antimony and nitre, thus made: Take an equal quantity of each, powder them separately, then mixing them well together, throw the mixture by degrees into a red-hot crucible, where it is to remain till melted thoroughly; this, after being separated from the scoriae, is to be kept for use. By boiling this crude crocus, first reduced to a fine powder, in water, and afterwards washing it with more hot water, till it comes off insipid, is obtained the washed crocus of antimony.

CROE, or CROME, an iron bar with a flat end: also a notch in the side-boards of a cask, where the head-pieces come in.

CROFT, a little close adjoining a dwelling house, and enclosed for pasture or arable land; or any other particular use.

CROISADE, CRUSADE, or CRUZADO, a name given to the expeditions of the Christians against the infidels, for the conquest of Palestine; so called because those who engaged in the undertaking wore a cross on their cloaths, and bore one on their standard.

CROISIERS, *Cruisieri*, cross bearers, a religious order founded in honour of the invention or discovery of the cross, by the empress Helena.

CROISSANTE, in heraldry, is said of a cross, the ends of which are fashioned like a crescent or half moon. See CROSS.

CROSETTES, in architecture, the returns in the corners of chambranes, or door cases, or window frames, called also ears, elbows, anions, &c.

CROSIER, or CROZIER, a shepherd's crook; a symbol or pastoral authority, consisting of a gold or silver staff, crooked at the top, carried occasionally before bishops and abbots, and held in the hand when they give the solemn benedictions. The custom of bearing a pastoral staff before bishops is very ancient. Regular abbots are allowed to officiate with a mitre and crozier. Among the Greeks none but a patriarch had a right to the crozier.

CROSIER, in astronomy, four stars in the southern hemisphere, forming a cross. These stars have too great southern latitude to be ever observed at the Royal Observatory; and therefore come not properly in our catalogue: notwithstanding, as they are said to be of great use to navigators in southern latitudes, we shall give their right ascension and declinations, as they have been settled from observations made by the late Abbé de la Caille; whose

authority, we believe, need not in this case be questioned. They are reduced to the same time with the other stars in this dictionary, viz. 1770.

Order.	Magn.	Name.	Right Ascension.	Declination South.	Var. in Right Ascen.	Var. in Declination.
1	3	δ	180.46.05	57.28.11	46.5	20.04
2	1	α	183.30.00	61.49.28	48.3	20.01
3	2	γ	184.45.23	70.51.34	50.4	19.97
4	2	β	188.36.46	58.25.45	51.3	19.83

CROSLET, in heraldry, is when a cross is crossed again at a small distance from each of the ends. Upton says it is not so often borne by itself in arms, as other crosses are, but often in diminutives, that is, in small croslets scattered about the field.

CROSS, *Cruz*, in antiquity, a species of punishment, or rather the instrument wherewith it was inflicted, consisting of two pieces of wood crossing each other.

Cross, in heraldry, is defined by Guillim, an ordinary composed of four-fold lines, whereof two are perpendicular, and the other two transverse; for so we must conceive of them, though they are not drawn throughout, but meet, by couples, in four right angles, near about the fesse-point of the escutcheon. The contents of a cross is not always the same; for when it is not charged, it has only the fifth part of the field; but if it be charged, then it must contain the third part thereof.

Cross-JACK, in naval affairs, a sail extended on the lower-yard of the mizen-mast, called hence the cross-jack yard. This sail, however, is very seldom used.

Cross-PIECE, in naval affairs, a piece of wood extended over the windlafs in merchant ships to fasten ropes to: the two ends of it are let into the knight-heads. See **KNIGHT-HEADS**.

Cross-STAFF, the same with fore-staff. See the article **FORE-STAFF**.

Cross-STAFF, in surveying, an instrument, sometimes made of brass; but oftener of wood: when it is of brass, it consists of a circle, divided into four quadrants, by two lines intersecting each other at right angles in the center; and at the four points where those intersect the circumference, are fixed four sights, slit with a fine thread in each, in the same manner as in the theodolite, and under each slit, a small sight-hole. When it is made of wood it is nothing more than a perfect square, with two slits, cut with a saw, in a diagonal manner, from corner to corner, which it is evident will intersect one another at right angles in the middle: and in both cases it is mounted on a staff. The use of this instrument is as follows:

Let **ABCDE** (Plate XXXIX. fig. 8.) be a field, or piece of land to be measured; when you go into it, look round and consider in what manner it can be most commodiously divided into triangles; which suppose the triangles **ABC**, **CDE**, and **ACE**: with your chain begin and measure from **A** in a right-line towards **C**; but when you imagine you come near **a**, set up your cross, and direct two of the sights, or one slit (if your cross be a wooden one) towards **A** and **C**, which being done, if through the other you can see **E**, then are you sure you are in the point where the perpendicular **Ea** will fall; but if you cannot, move it a little one way or other, as you find occasion, until you can; which being done, measure from your staff to **E**, the perpendicular **aE**, and then continue your measuring towards **C**; but when you come to **b**, you must observe the same directions, with regard to the perpendiculars **Bb**, as was given for **aE**, and then measure on to **C**. This being done, will have the base **AC**, and two perpendiculars **aE**, and **Bb** of the triangles **ABC**, and **AEC**; whence by the common rule for measuring triangles, their content will be easily found: and if the same be observed, with regard to the triangle **CDE**, and the three areas added together, it will give the area of the whole piece, if all the sides be right-lines: but if they be curved or crooked, as the sides **AE** or **CD**, it is evident this method can never give the true content; for if it be bent outwards, as **CD**, it will give the area of the triangle **CDE** too much by the space, included between the side **CD**, and the straight dotted line; and if it be bent inward, as **AE**, it will give the area too small, by the space included between that side and dotted line **AE**: and in either of these cases, another method of surveying must be made use of by those who would be accurate artists. See the article **SURVEYING**.

Cross-TREES, certain pieces of timber laid across the heads of the lower-masts to make a frame for the top to rest on. The use of the top is to extend the shrouds of the top-masts, that they may support it the better.

CROSSELET, a little or diminutive cross, used in heraldry, where the shield is frequently seen covered with crosselets; also fesses and other honourable ordinaries, charged or accompanied with crosselets. Crosses frequently terminate in crosselets.

CROTAPHITES, in anatomy, a muscle of the lower jaw, serving to draw it upwards. Its fibres spring from the bones of the forehead, the sinciput, sphenoides, and temporale, which meeting, and as it were entering under the os jugale, whence also this muscle receives some fibres, proceed to the processus corone, into which they are inserted.

CROTCHES, in naval architecture, certain crooked timbers in the after-hold, on which to form the

the narrower parts of a ship as she approaches to the stern.

CROTCHES are also certain crooked pieces of wood or iron, fixed in different places of the ship to support the spare-masts, &c.

CROTCHET, in music, one of the notes or characters of time, marked thus ♯, equal to half a minim, and double of a quaver. See the articles **CHARACTER**, **MINIM**, and **QUAVER**.

A dot added to the crotchet, thus ♯., increases its time by one half, that is, makes it equal to a crotchet and a half.

CROTCHET, in printing, a sort of straight or curved line, always turned up at each extreme; serving to link such articles as are to be read together; and used in analytical tables, &c. for facilitating the divisions and subdivisions of any subject.

CROTCHETS are also marks or characters, serving to inclose a word or sentence, which is distinguished from the rest, being generally in this form [] or this ().

CROTOLARIA, in botany, a genus of plants, whose flowers is papilionaceous; and contains ten stamina, joined together.

The fruit is a short twig legumen or pod, opening with two valves, and filled with reniform seeds.

CROTON, in botany, a genus of plants, producing male and female flowers. The male flowers of which being less than the female, consist of five oblong, obtuse petals, scarce larger than the cup, with ten or fifteen stamina. The petals of the female flower are the same as in the male.

The fruit is a roundish capsule, with cells, each cell having two valves, and contains in each a solitary, large, ovated seed.

This is the ricinoides of Tournefort.

CROUP of a Horse, in the manege, the extremity of the reins above the hips.

CROUPADE, in the manege, a leap, in which the horse pulls up his hind legs, as if he drew them up to his belly. Croupades differ from caprioles and balotades, in this, that in croupades the horse does not jerk, as he does in the other two airs.

CROW, or **CARRION-CROW**, in ornithology, the English name of a species of corvus, about the size of the largest tame pigeon; and all over of a fine deep black colour, with large eyes and reflex bristles at the nostrils.

Royson CROW, the English name of another species of corvus, with the body grey, the head, throat, wings, and tail, black.

CROW, in mechanics, a kind of iron lever with a claw at one end, and a sharp point at the other; used for heaving or purchasing great weights.

CROW'S BILL, among surgeons, a kind of forceps for drawing bullets and other foreign bodies out of wounds.

CROW'S FEET, in the military art, machines of iron, having four points, each about three or four inches long, so made that whatever way they fall, there is still a point up: they are thrown upon breaches or in passes where the enemy's cavalry are to march, proving very troublesome by running into the horse's feet and laming them.

CROW-FOOT, in naval affairs, a certain complication of ropes that spread outward from a block to hang the awnings by, or keep the top-fails from getting against the edges of the tops.

CROW-FOOT, in botany, the English name of the ranunculus. See **RANUNCULUS**.

CROW-STAVES, the two upright pieces inserted into the box of a plough, and bored with a number of holes, by means of which they support a transverse piece, called the pillow of the plough. See the articles **PLOUGH** and **PILLOW**.

CROWN, an ornament worn on the head by kings, sovereign princes, and noblemen, as a mark of their dignity.

The Roman emperors had four kinds of crowns, still seen on medals, viz. a crown of laurel, a radial or radiating crown, a crown adorned with pearls and precious stones, and the fourth a kind of bonnet or cap, something like the mortier.

CROWN, in commerce, a general name for coins both foreign and domestic, which are of, or very near, the value of five shillings sterling.

CROWN, in architecture, denotes the uppermost member of the cornice, called also corona, and larmier. See the articles **CORONA** and **LARMIER**.

CROWN, in astronomy, a name given to two constellations, the one called borealis, the other meridionalis. See the article **CORONA**.

CROWN, in geometry, is a plane ring included between two concentric perimeters, and is generated by the motion of some part of a right line round a center, the said moving part not being contiguous to the center.

The area of a crown will be had by multiplying its breadth by the length of the middle periphery; for a series of terms in arithmetic progression being $n \times \frac{a+w}{2}$, that is, the sum of the first and last multiplied by half the number of terms, the middle element must be $\frac{a+w}{2}$; wherefore that multiplied by the breadth, or sum of all the two terms, will give the crown.

CROWN of Colours, certain coloured rings which like halos appear about the body of the sun or moon, but of the colours of the rain-bow, and at a less distance than the common halos. These crowns Sir Isaac Newton shews to be made by the sun's shining in a fine day, or the moon in a clear night, through a thin cloud of globules of water or hail, all of the same bigness. And according as the globules

bules are bigger or lesser, the diameters of these crowns will be larger or smaller; and the more equal these globules are to one another, the more crowns of colours will appear, and the colours will be the more lively.

CROWN-GLASS denotes the finest sort of window-glass. See the article **GLASS**.

CROWN-IMPERIAL, in botany. See the article **FRITILLARIA**.

CROWN-OFFICE, an office that belongs to the King's bench-court, of which the king's coroner or attorney is commonly master. In this office, the attorney-general and clerk of the crown severally exhibit informations for crimes and misdemeanors at common law, as in the case of batteries, conspiracies, libelling, &c. on which the offender is liable to pay a fine to the king.

CROWN-POST, in architecture, a post which in some buildings stand upright in the middle between two principal rafters, and from it there go struts or braces to the middle of each rafter. It is sometimes called a king's piece, or joggle piece.

CROWN-WHEEL of a *Watch*, the upper wheel next the balance, which by its motion drives the balance, and in royal pendulums is called the swing-wheel.

CROWN-WORK, in fortification, an out-work having a very large gorge, generally the length of the curtain of the place, and two long sides terminating towards the field in two demi-bastions, each of which is joined by a particular curtain to a whole bastion, which is the head of the work. The crown-work is intended to inclose a rising ground, or to cover the head of a trenchment.

CROWNING, in architecture, is understood of any thing that finishes a decoration. Thus a cornice, a pediment, a croteria, are called crownings.

CROWNING, in naval affairs, the finishing part of a knot made by the ends of the different strands of a rope, being artfully intertwisted amongst each other to keep the end fast in some place assigned for it.

CRUCIANELLA, in botany, a genus of plants, whose flower consists of a single petal: the tube is cylindrical, and the border is quadrifid and small: it hath four stamina; and the fruit is two capsules, growing together, each containing an oblong seed.

This is the *rubeola* of Tournefort.

CRUCIBLE, a chemical vessel made of earth, and so tempered and baked as to endure the greatest heat. They are used to melt metals, and to flux minerals, ores, &c.

The figure of a crucible is commonly that of an obtuse conoid, with its base at the top, and obtuse apex at the bottom; whence this conical figure may be varied, till it comes to the hollow segment of a sphere. It is a rule that the lower and wider they are made, the more easily the volatile matter flies

from the fixed, and that the fire is applied to more of the surface, both of the whole subject and its fixed part.

CRUCIFIX, a cross upon which the body of Christ is fastened in effigy, used by the Roman catholics to excite in their minds a strong idea of our Saviour's passion.

CRUCIFORM, in general, something disposed cross-wise; but more especially used by botanists, for flowers consisting of four petals disposed in the form of a cross: such are the flowers of cabbage, rocket, wall-flower, &c. See **FLOWER**.

From this structure of the flower, Tournefort has denominated one of his classes of plants *cruciformes*; comprehending all plants with cruciform flowers, called by Linnaeus *tetradynamia*.

CRUCIS EXPERIMENTUM. See the article **EXPERIMENTUM CRUCIS**.

CRUDE, an epithet given to something that has not passed the fire, or had a proper degree of coction.

CRUDITY, among physicians, is applied to undigested substances in the stomach; to humours in the body which are uncocted, and not prepared for expulsion; and to the excrements.

The crudity of the humours or morbid matter in a disease, is discovered chiefly from a fault in the quantity or quality of the circulating as well as the secreted humours, as of sweat, mucus, saliva, urine, pus, blood, &c.

CRUOR, among anatomists, sometimes signifies the blood in general; sometimes only the venous blood; and sometimes extravasated, or coagulated blood.

CRUPPER, in the manege, the buttocks of a horse, the rump; also a thong of leather put under a horse's tail, and drawn by thongs to the buckle behind the saddle, so as to keep him from casting the saddle forwards on his neck.

CRURA CLITORIDIS, in anatomy, two legs of the clitoris, which run from the ossa pubis, and are three times as long as the clitoris in its natural state. See the article **CLITORIS**.

CRURA MEDULLÆ OBLONGATÆ, the two largest legs or roots of the medulla oblongata, which proceed from the cerebrum.

CRURÆUS, or **CRUREUS MUSCULUS**, in anatomy, a fleshy mass, covering almost all the fore-side of the os femoris, between the two vassi, which likewise cover the edges of this muscle on each side. It is fixed to the fore-side of the os femoris, from the anterior surface of the great trochanter, down to the lowest quarter of the bone, by fibres which run down successively over each other, between the two vassi, and are partly united to these two muscles, so that they do not seem to form a distinct muscle.

CRURAL, in anatomy, an epithet given to the artery

artery which conveys the blood to the crura, or legs, and to the vein by which this blood returns towards the heart.

CRUS, in anatomy, all that part of the body contained between the buttocks and the toes; it is divided into thigh, leg, and foot. See THIGH, LEG, and FOOT.

CRUSCA, an Italian term signifying bran, is in use amongst us to denote that celebrated academy called Della Crusca, established at Florence, for purifying and perfecting the Tuscan language.

CRUSTA VILLOSA, in anatomy, the fourth tunic, or coat, of the stomach. See the article STOMACH.

CRUSTA LACTEA, in medicine, the same with achor, being scabby eruptions with which the heads of children are often troubled. See the article ACHOR.

CRUSTACEOUS, an appellation given to animals covered with shells made up of several pieces, in contradistinction to those consisting of a single piece: the former are known, among authors, by the name of malacostraca; and the latter, by that of testaceous. See the articles MALACOSTRACA and TESTACEOUS.

CRUZADO, the same with croisade. See the article CROISADE.

CRUZADO, in commerce, a Portuguese coin; struck under Alphonfus V. about the year 1457, at the time when pope Calixtus sent thither the bull for the croisade against the infidels.

CRYMODES, among physicians, a kind of fever attended with a shivering cold and inflammation of the internal parts of the body. See the article FEVER.

CRYPTOGAMIA, κρυπτες, hid, and γαμος, marriage, a name given by Linnæus to the twenty-fourth class of plants in his system of botany. This class consists of such plants, whose organs of fructification is either concealed within the fruit itself, or so minute, as not to be perceptible to the naked eye. The fructification in these is also of an uncommon structure. To this class belong the ferns, mosses, &c. See the articles FERN, MOSS, &c.

CRYPTOGRAPHY, the art of writing in cypher, or with sympathetic ink. See the articles CYPHER and INK.

CRYSTAL, κρυσταλλος in natural history, the name of a very large class of fossils; hard, pellucid, and naturally colourless; of regularly angular figures, composed of simple, not filamentous plates; not flexible nor elastic, giving fire with steel; not fermenting in acid menstrua, and calcining in a strong fire.

CRYSTAL, is also used for a factitious body, cast in glass-houses, called crystal-glass; being, in fact, no more than glass carried, in the composi-

tion and manufacture, to a greater perfection than the common glass.

CRYSTALS, in chemistry, salts or other matters shot, or congealed, in manner of crystal.

CRYSTALS of Silver, or Lunar Crystals, are silver reduced into the form of salts, by the pointed acids of spirit of nitre. These crystals are like the solutions of an immediate caustic: they burn the skin on the slightest touch.

CRYSTALLI, among physicians, eruptions about the size of a lupin, white and transparent, which sometimes break out all over the body.

CRYSTALLINE, in general, something composed of, or resembling crystal. See the article CRYSTAL.

CRYSTALLINE HEAVENS, in ancient astronomy, two spheres, imagined between the primum mobile and the firmament, in the Ptolemaic system, which supposes the heavens solid, and only susceptible of a single motion. See the article PTOLEMAIC SYSTEM.

CRYSTALLINE HUMOUR, in anatomy, a thick, compact humour, in form of a flattish convex lens, situated in the middle of the eye, serving to make that refraction of the rays of light, necessary to make them meet in the retina, and form an image thereon, whereby vision may be performed. See EYE.

CRYSTALLIZATION, in chemistry, the reducing salts to their proper specific or crystalline form; so called from their resembling crystals.

CRYSTALLOIDES, the crystalline tunic of the eye; a fine membrane containing the crystalline humour.

CUB, a bear's whelp. Among hunters, a fox and a marten of the first year, are called cubs.

CUBATURE of a Solid, in geometry, the measuring the space contained in it; or finding the solid contents of it.

CUBE, in geometry, a solid, contained under six equal square sides. Its solidity is found by multiplying the length of one of its sides twice into itself: Thus, if the length of the side were four inches, &c. $4 \times 4 \times 4 = 64$, the solidity required.

CUBEBS, *Cubeba*, dried berries, greatly resembling pepper, but furnished each with a slender stalk, whence they are called by some, *piper caudatum*. They are the fruit of an East-Indian tree, of which we have no particular account, said to resemble the apple-tree, and to produce its berries in clusters.

CUBIC Numbers, in arithmetic, are such as are formed by the multiplication of some one number twice into itself: Thus $4 \times 4 \times 4 = 64$ a cubic number; hence by comparing this with the foregoing article, it is easy to see the analogy there is between the geometrical solid, called a cube, and a cube number in arithmetic.

There are a great many remarkable properties in cubic

cubic numbers, which may be seen in most books of arithmetic and algebra, but which it is foreign to our province to take notice of here.

CUBIC Quantities, in algebra, wherein any quantity, as x is involved to the third power; that is, multiplied twice into itself, as was said of numbers, and it is expressed by xxx , or x^3 ; this is called a simple cubic quantity: a compound one is formed of the continued multiplication of two simple quantities, connected with the signs $+$ or $-$: as $x + y$ involved to the third power is $x^3 + 3x^2y + 3xy^2 + y^3$; that of $x - y$ is $x^3 - 3x^2y + 3xy^2 - y^3$. See *Multiplication of ALGEBRA*.

CUBIC Equation, in algebra, is an equation whose highest power is of three dimensions, that is, has the unknown quantity involved to the power, as $x^3 = a + b$, or $x^3 + ax^2 + bx = d$.

All cubic equations have three different roots either possible or impossible; but any one of them being once obtained, the rest may easily be found.

Thus, for example: The equation $x^3 - 4x^2 + 7x - 6 = 0$, has only one real root, which is 2, and two impossible ones: Now those impossible ones may be easily found from having the real one given thus. Divide the equation $x^3 - 4x^2 + 7x - 6 = 0$, by $x - 2$, the quotient $x^2 - 2x + 3$, must certainly be equal to nothing, since both the dividend and divisor are so; whence we have $x^2 - 2x = -3$, and by completing the square and proper reduction, we get $x = 1 \pm \sqrt{-2}$ the two roots required, for either of those being wrote in the equation for x , will make all its terms destroy one another, equally with the number 2, but then those are called impossible roots, because they require the extraction of the square root out of the negative number 2. Again, if $x^3 = a^3$ was given, we should have, beside $x = a$, the possible root; $x = a \times \frac{1}{2} \pm \sqrt{-\frac{3}{4}}$, two other values of x .

But it may not perhaps be amiss to observe here, that it very often happens, more especially in the solution of geometrical problems, that the roots of equations are possible, when the cases to which they relate, may exhibit them impossible. As for example:

Let ABC, (Plate XXXIX. fig. 9.) be a circle whose diameter is AC, and let AB be any chord inscribed in it; from B, the end of the chord, draw the line BD perpendicular to the diameter AC; and let it be required, having given the lines AB and AC, to compute AD, the segment of the diameter intercepted between the point A and D the foot of the perpendicular. Join BC, and call AD x : then will the similar triangles ADB and ABC give the following proportion, to wit, AC is to AB as AB is to AD or x ; whence $x = \frac{AB^2}{AC}$; therefore x , the root of this equation, will be equally possible, whether AB be greater or less than

AC; but the problem will not be possible unless the chord AB be less than the diameter AC. Here then we have an instance of a problem's producing an equation whose root continues to be possible, even when the problem ceases to be so, on account of the limitation abovementioned, to wit, that the problem AB must be less than AC. To explain this mystery, let AC and AB be any two given lines, and let it be required to assign a third proportional to them, which we call x : since then AC is to AB, as AB is to x , we have again $x = \frac{AB^2}{AC}$: but this

problem is as unlimited as the equation it produces; for it is certain the two quantities AC and AB will admit a third proportional, whether AB be greater or less than AC. The case then stands thus: here is an equation arising from a limited problem; but this equation is also intended to solve another problem that is absolutely unlimited; therefore it ought not to be expected that the equation should be liable to any restriction; whatever may be the case of the problem that produced it.

The following method of solving cubic equations by means of the right-angled triangle ABC (Plate XXXIX. fig. 10.) as given by the late Mr. Cotes, we apprehend will be acceptable to our readers. He considers all cubic equations under this one general form, viz. $x^3 \pm 3a^2x = \pm 2a^2b$; and the triangle right at A, as having always two sides given, representing the known quantities a and b in the equation.

Case I. If the equation be $x^3 + 3a^2x = \pm 2a^2b$, make $AB = a$, $AC = b$; and let m and n be two mean proportionals between BC + CA and $BC - CA$: then will $m - n$ be the only possible affirmative root, or $n - m$ the only possible negative root in the equation, according as the absolute term is $+$ or $- 2a^2b$.

Case II. If the equation be $x^3 - 3a^2x = \pm a^2b$, and a be less than b ; make $AB = a$, $BC = b$, and let m and n be the only possible affirmative root, and $-m - n$ the only possible negative one, accordingly as the absolute term is $+$ or $- 2a^2b$.

Case III. If the equation be $x^3 - 3a^2x = \pm a^2b$, and a be greater than b , make $AB = b$, $BC = a$, and let m be the sine of one-third part of the sum of the two angles A and B, and n the sine of a third part of their difference, in a circle whose radius is $2BC$; then will the three roots of the equation be $m + n$, $-m$ and $-n$, or $+m$, $+n$, and $-m - n$, according as the absolute term is $+$ or $- 2a^2b$.

The analogy of these three cases, consists in this; that whereas the two first cases are resolved by the sum and difference of the sides BC and CA, the last case is resolved by the sum and difference of their opposite angles A and B: and whereas the two first cases were obtained by the trisection of a ratio,

in the last they are had by the trisection of an angle.

Those who are curious to see a demonstration of the preceding elegant method of solution, may have ample satisfaction, by consulting Sanderfon's Algebra, page 719.

CUBIC Hyperbola. See **HYPERBOLA**.

CUBIC Parabola. See **PARABOLA**.

CUBIT, in the mensuration of the ancients, a long measure, equal to the length of a man's arm, from the elbow to the tip of the fingers.

Dr. Arbuthnot makes the English cubit equal to eighteen inches; the Roman cubit equal to 1 foot, 5,406 inches; and the cubit of the Scripture equal to 1 foot, 9,888 inches.

CUBITÆUS, in anatomy, the name of two muscles; the one called cubitæus externus, being the first of the extensor muscles of the fingers, arises from the external extubérance of the humerus, and passing its tendon under the ligamentum annulare, is inserted into the fourth bone of the metacarpus that sustains the little finger: the other is the cubitæus internus, which ariseth from the internal extubérance of the humerus, and the upper part of the ulna, upon which it runs all along, till it passes under the ligamentum annulare, and is inserted, by a strong and short tendon, into the fourth of the first order of the carpus.

CUBITUS, in anatomy, a bone of the arm, reaching from the elbow to the wrist, otherwise called the ulna. The cubitus, for the sake of the more easy and varied motion, is composed of a binary number of bones, called the cubitus, or ulna, and the radius. The situation of the ulna is interior, its length is greater than that of the radius, and has a motion of flexion and extension.

CUBOIDES, or **Os CUBOIDES**, in anatomy, the seventh bone of the foot, so called from its resembling a cube. It is situated in the external side of the tarsus, where it receives the outer bone of the metatarsus, and is articulated with the neighbouring bones.

CUCKOO, in ornithology, the English name of a well known bird, called by zoologists, cuculus. See **CUCLUS**.

CUCKOO-FLOWER, in botany, a name sometimes given a plant, more generally called cardamine, or lady's smock.

CUCKOO-PINT, in botany, the English name of the arum. See **ARUM**.

CUCKOO-SPIT, the same with froth-spit. See the article **FROTH-SPIT**.

CUCUBALUS, in botany, a genus of plants, whose flower consists of five petals, the ungues of which are of the length of the cup. The filaments are awl-shaped, and ten in number, topped with oblong antheræ. The fruit is a close acuminate capsule, opening at the top in five parts, and contains a number of roundish seeds.

CUCULLARIS, in anatomy, a muscle of the scapula, otherwise called trapezius: it arises from the os occipitis, the spinose apophyses of the neck, and of the seventh and eighth of the back. Its termination is at the spine of the scapula. It has the power of several very different motions; the different course of its several fibres enabling it, as they act differently, to move the scapula upwards, downwards, or backwards.

CUCULUS, the cuckoo, in ornithology, a genus of birds, of the order of the picæ, the characters of which are these: the beak is smooth; the nostrils are a little prominent; the tongue is entire, and faggitated; the toes are four in number, two before and two behind.

The common cuckoo is a bird of considerable beauty, which breeds with us, but does not remain all the year.

Its head, neck, and back, are of a hoary colour, with some dark grey feathers; the wings are of a brownish black, the throat of an undulated flesh colour, and the belly whitish. The colour of the female differs but very little from that of the male.

CUCUMBER, *Cucumis*, in botany, a genus of plants which trail on the ground, on which the leaves are alternately disposed, serrated on their edges, and rough to the touch; they are furnished with tendrils, and the flowers proceed from where the leaves join the stalk. There are male and female placed at distances on the same plant; both are camanulated and monopetalous, and cut into five ovated rough segments. The male flower hath three very short filaments inserted in the calyx, two of which have bifid tops; these are terminated by small linear antheræ. The female flowers have no stamina, but are furnished with three small acuminate filaments, with a short, cylindraceous style. The fruit is oblong, trilocular, and fleshy, and contains a number of oval, flat, pointed seeds.

There are several varieties of cucumbers, some of which are raised very early in the spring on hot-beds, and so very eager are many narrow-minded gardeners, to cut a cucumber a day or two sooner than their neighbours, that they possess themselves with a belief, that it is the ultimatum of gardening; and therefore give themselves but little trouble with the other branches of their profession, if they excel in this.

The art of raising cucumbers early depends upon the judgment, care, and practice of the person who undertakes it; for although many gardeners pretend to mysteries in this art, it depends wholly upon the following rules, viz. to throw up some new hot dung for a week or ten days, in order to foment and evaporate the stench; to make the bed where they are to grow even and true; and when the extreme heat is off, after the bed is earthed, (which should not be too much at first, lest it should burn)

to put the plants out carefully; to give air to the plants at all opportunities; but this must be done with great caution, for if too much is let in, the plants will be destroyed, as they are extremely tender; and if they have too little, they are either drawn up weak, or else destroyed by the steam of the dung. It is impossible to give precise rules for this regulation, as it intirely depends upon the practice and judgment of the manager. As the plants continue to advance in growth, they should have more earth added to them, and their extremities shortened, in order to put forth the sooner lateral shoots, which produce the fruit, and from time to time they should be kept thinned, otherwise they would grow in confusion. When the heat of the bed is beginning to decline, some fresh dung should be laid round the sides, observing not to line higher than the bed; upon this barley straw, coarse hay, &c. may be continued up to the top of the box; when the bed is in good heat they may be watered, if the earth is dry, taking the opportunity of good weather. The glasses should be covered at night in proportion to the heat of the bed and warmth of the weather, and at the time of blowing, to give as much air as possible, without detriment.

The young plants are raised from seeds under a glass on hot dung, and afterwards, either pricked out on a bed prepared, or in pots, and plunged in the same.

The first season for sowing cucumbers is at Christmas, or the beginning of January, and the last is about the end of May. This is done in the natural ground, and their produce is made use of for pickling.

Cucumbers are very cooling and viscid, and therefore apt to dispose the blood to putrid fermentations. They do well therefore who dress them with a good quantity of vinegar and pepper; for as the former helps to keep up the due tenacity and contraction of the solids, the other preserves the proper fluidity of the juices, and prevents them from running into morbid cohesions; they are likewise pretty well secured against the above-mentioned mischiefs, by pickling with the like ingredients. The seeds are reckoned among the four greater cold feeds; these are cooling, and sometimes emulsions of them have been prescribed in burning fevers, a fit of the gravel, and heat of urine. To this genus Linnæus has added the melo, colocynthis, and anguria of Tournefort.

Wild CUCUMBER, in botany. See the article *MOMORDICA*.

CUCURBIT, in chemistry, an earthen or glass vessel, so called from its resemblance to a gourd, arising gradually from a wide bottom, and terminating in a narrow neck.

Blind CUCURBIT is a small inverted cucurbit, adapted to another in such a manner, that the neck

of the one is inserted in that of the other. The vessel called *circulatory* is one of this kind.

CUCURBITA, in botany, the gourd or pom-pion, a genus of plants, whose flower is a campanulated petal, divided into five segments, some of which are male and others female. The fruit is large and fleshy, and contains three membranaceous cells, inclosing a number of compressed, tumid, obtuse seeds, placed in two rows. There are several species of cucurbita, some of which produce fruit of a monstrous size, either round or long. They are raised from seeds, and cultivated here more for curiosity than use, though in America they use them as sauce with their meat. An old dunghill is the best place to raise them upon, where they will spread to a great distance, and bear plenty of fruit.

CUCURBITULA denotes a cupping-glass. See the article *CUPPING*.

CUD, sometimes means the inside of the throat in beasts, and sometimes the food that they keep there, and chew over again: from whence, to chew the cud, signifies, to ponder, think, or ruminate upon a thing.

CUD LOST, implies cattle that sometimes lose their cud by chance, sometimes by sickness, poverty, mourning, &c. to cure which, take four leaven of rye bread, and salt, and mixing it with human urine and baum, beat it in a mortar; then making a large ball or two thereof, put them down the beast's throat.

CUD-WEED, in botany. See *GNAPHALIUM*.

CUE, among stage-players, an i em, or inuendo, given to the actors on the stage, what, or when to speak.

CUIRASSE, a piece of defensive armour, made of plate, well hammered, serving to cover the body, from the neck to the girdle, both before and behind: whence

CUIRASSIERS, cavalry armed with cuirasses, as most of the Germans are: the French have a regiment of cuirassiers: but we have had none in the English army, since the Revolution.

CUL de Lamp, in architecture, a term used for several decorations, both of masonry and joinery, found in vaults and ceilings, to finish the bottom of works, and wreathed something in the manner of a testudo, particularly a kind of pendentive in Gothic vaults.

CUL de Four, a sort of spherical vault, like an oven. See the article *VAULT*.

CUL de Four of a Niche, signifies the arched roof of a niche, on a circular plan.

CULDEES, in church history, a sort of monkish priests, formerly inhabiting Scotland and Ireland. Being remarkable for the religious exercises of preaching and praying, they were called, by way of eminence, *Cultores Dei*; from whence is derived the word *Culdees*. They made choice of one of their

their own fraternity to be their spiritual head, who was afterwards called the Scotch bishop.

CULLIAGE, a barbarous and immoral practice, whereby the lords of manors anciently assumed a right to the first night of their vassals brides.

CULM, among botanists, a term used to denote the stalk of grasses, hence called culmiferous plants. See the next article.

CULMIFEROUS Plants, in botany, such plants as have a smooth jointed stalk, usually hollow, and at each joint wrapped about with single, narrow, sharp-pointed leaves, and their seeds contained in chaffy husks, as wheat, barley, &c.

CULMINATION, in astronomy, is a term applied to any one of the heavenly bodies when it is on the meridian.

Line of CULMINATION, the same with meridian line.

CULPRIT, a formal reply of a proper officer in court, in behalf of the king, after a criminal has pleaded not guilty, affirming him to be guilty, without which the issue to be tried is not joined. After an indictment, for any criminal matter, is read in court, the prisoner at the bar is asked whether he is guilty, or not guilty, of the indictment? If he answers, not guilty, there is a replication by the clerk of the arraignments from the crown, by continuing the charge of the guilt upon him, which is expressed in the word *culprit*.

The term *culprit* is a contraction of the Latin *culpabilis*, and the French *prêt*; importing that he is ready to prove the criminal guilty.

CULVERIN, in the military art, a large cannon, or piece of artillery, for the kinds, weight, and proportion of which, see the article *CANNON*.

CULVERTAILED, among ship-wrights, signifies the fastening, or letting of one timber into another, so that they cannot slip out, as the carlings into the beams of a ship.

CUMMIN, *Cuminum*, in botany, an annual, umbelliferous plant, seldom rising to a foot in height; the leaves are divided into long, narrow parts, like those of fennel, but much less; the flowers grow in small umbels on the top of the stalks; these are small, roseaceous, and composed of five unequal petals, of a pale bluish colour, and are succeeded by longish, slender, plano-convex seeds, of a brownish colour, with pale yellowish striae.

This plant is a native of Egypt and Ethiopia, and cultivated in the islands of Sicily and Malta, from whence we are supplied with the seeds.

The seeds of this plant is the only part used in medicine; they have a bitterish warm taste, accompanied with an aromatic flavour, but not agreeable, with a very strong smell; it is one of the four greater hot seeds, consisting of very warm dissolving parts, and accounted carminative and stomachic. They are also used externally in cataplasms

and fomentations, wherever a warm discutient is required.

CUNEIFORM, in general, an appellation given to whatever resembles a wedge.

The word is formed from the Latin *cuneus*, a wedge, and *forma*, resemblance.

CUNEIFORM-BONE, in anatomy, the seventh bone of the cranium, called also *os basilare*, and *os sphenoides*. See the article *SPHENOIDES-OS*.

CUNEIFORM-BONES, or *OSSA CUNEIFORMIA*, are also three bones of the foot, all different in their sizes, and articulated with the *os naviculare*, and with the three bones of the metatarsus, viz. those which support the great toe, the second, and the third. See the articles *METATARSUS* and *NAVICULARE*.

CUNETTE, or *CUVETTE*, in fortification, a deep trench, about three or four fathoms wide, sunk along the middle of a dry moat, to make the passage more difficult to the enemy.

CUNEUS, the wedge, in mechanics. See the article *WEDGE*.

CUNEUS, in antiquity, a company of infantry, drawn up in form of a wedge, the better to break through the enemy's ranks.

CUNILA, in botany, a genus of plants, whose flower is monopetalous and ringent; it contains two filiform filaments, topped with double antheræ, it has no pericarpium; the cup contains four minute oval seeds.

CUNNING, amongst seamen, the art of directing the steersman to guide the ship in her proper course: the officer who has this charge is either the pilot or quarter-master.

CUP, a vessel of capacity of various forms and materials, chiefly used to drink out of.

CUP, among botanists, the same with calyx. See the article *CALYX*.

CUPOLA, in architecture, a spherical vault; or the round top of the dome of a church, in form of a cup inverted. See the article *DOMÉ*.

CUPPEL, or *Coppel*, in chemistry. See the article *COPEL*.

CUPPING, in surgery, the operation of applying cupping-glasses for the discharge of blood, and other humours, by the skin.

The operation of cupping is not confined to any particular member of the body; but wherever the cupping-glass is applied, it is fixed upon the skin, either intire or scarified, and hence we have a twofold distinction of cupping, into dry and gorey.

In dry cupping, the glass adheres to the skin, by expelling or rarefying its included air by lighted flax, or the flame of a burning candle within it, so that the glass is pressed upon the part with a considerable force, by the external air. The use of this dry-cupping is two-fold, either to make a revulsion of the blood, from some particular parts affected, or else to cause a derivation of it into the affected part, upon

upon which the glass is applied: hence we have a reason why Hippocrates orders a cupping-glass to be applied under the breasts of a woman who has too profuse a discharge of her menses, intending thereby to make a revulsion of the blood upwards from the uterus. Dry cupping is also used, with success, to make a revulsion, by applying the glasses to the temples, behind the ears, or to the neck and shoulders, for the removal of pains, vertiges, and other disorders of the head: they are applied to the upper and lower limbs, to derive blood and spirits into them, when they are paralytic; and, lastly, to remove the sciatica, and other pains of the joints. The operation in these cases is to be repeated upon the part, till it looks very red, and becomes painful.

In Germany, and other northern countries, cupping is much oftener joined with scarification, than used alone; in which case the part is first to be cupped, till it swells and looks red, and the skin is to be punctured, or incised, by the scarifying instrument.

As several glasses, sometimes six or eight, are often applied at once, the operator must manage his business so, that some glasses may be filling while he is scarifying, and adapting the others. When the blood ceases to flow fast enough, he must repeat his incisions, close by the former, and re-apply the cupping-glasses. The operation being finished, and the skin well cleansed with a sponge, and warm water, it is next to be rubbed over with a bit of deer's suet, to promote the healing: but if the blood still continues to flow, the skin is to be washed with spirit of wine and hungary water, binding it up with a compress and bandage.

The cupping-glass and instrument are represented in (Plate XL. *fig. 1.*)

This instrument consists of a brass box, on one of whose sides are a number of lancets moveable by a spring within the box. When this slide is applied to the skin, the spring is to be raised by the handle A; and on depressing the button B, it causes the lancets to pierce the skin all at once.

CUPRESSUS, the cypress-tree, in botany, a genus of coniferous trees.

The common cypress has a straight thick trunk, palish, and sometimes redish; and a very sweet smell. It is ever-green; and the leaves are like those of fawn, the shoots being very small, and seemingly covered with scales. The catkins of male flowers have very small leaves or scales, which have each four antheræ adhering to their bottom; but are destitute of a corolla. The female flowers are formed in a roundish cone; and are apetalous. The germen is scarce visible; but under each scale there are hollowed points in the place of styles.

The fruit is a subglobose cone, opening with roundish and pointed squamæ, under which is con-

tained the seed, being an angular acuminate small nut.

These trees are all propagated by sowing their seeds early in the spring on a bed of warm, dry, sandy earth, covering with the same about half an inch thick. In about two months time the young plants will appear above ground, and should be often watered: in two years time, they will be strong enough for transplantation into a nursery. The best season is about the middle of April, in a cloudy day. They may remain here three or four years, when they may be planted where they are to remain for good.

Cypress-trees are so very ornamental to gardens, that no large garden can be complete without many of them; and it is to these trees that the Italian villas owe a great share of their beauty: for there is no tree so proper to place near buildings; the pyramidal upright growth of their branches affords a picturesque appearance, and obstructs not the view of the building; and the dark green of their leaves make a fine contrast with the white of the building; so that wherever there are temples, &c. erected in gardens, there is no sort of tree so proper to place near them as these.

The timber of this tree is said to resist the worm, moth, and all putrefaction; and is said to last many hundred years. The doors of St. Peter's church at Rome were framed of this material, which lasted from Constantine the Great, to pope Eugenius the Fourth's time, which was eleven hundred years, and were then found entire, when the pope would needs change them for gates of brass. The coffins were made of this timber, in which, Thucydides tells us, the Athenians used to bury their heroes; and the mummy-chests, brought with those condited bodies out of Egypt, are many of them of this wood.

This tree is by many learned authors recommended for the improvement of the air, and a specific for the lungs, as sending forth great quantities of aromatic and balsamic scents; wherefore many of the ancient physicians of the eastern countries used to send their patients who were troubled with weak lungs, to the island of Candia, which at that time abounded with these trees, where, from the effects of the air alone, very few failed of a perfect cure.

CUPRUM, or **COPPER**, in natural history. See **COPPER**.

CURATE properly signifies the parson, or vicar of a parish, who has the charge, or cure, of the parishioners souls.

CURATE also implies a person substituted by the incumbent to serve his cure in his stead.

CURB, in the manege, a chain of iron, made fast to the upper-part of the branches of the bridle, in a hole, called the eye, and running over the horse's beard. It consists of these three parts, the hook fixed to the eye of the branch; the chain of SS's, or links; and the two rings or mailles.

Cupping

Fig. 1.

Fig. 3. Cycloid

Fig. 2.

Current

Cycloid

Fig. 5. Cycloid

Fig. 6. Cycloid

CURB is also a hard and callous swelling, that runs along the inside of a horse's hoof, in the great finew behind, above the top of the horn, which makes him halt, and go lame, when he has been heated. It is to be cured by the like applications as are prescribed in the spavin. See the article **SPAVIN**.

CURCUMA, turmeric, in botany. See the article **TURMERIC**.

CURDLING, the coagulating any fluid body, especially milk.

CURE of *Souls*, a benefice in the Christian church, the incumbent whereof has the direction of consciences within a parish.

CURETES, in antiquity, a sort of priests, called also Corybantes, being, as some relate, the same with what the Druids and Bards were afterwards among the Gauls.

CURFEW, or **COURFEW**, a signal given in cities taken in war, &c. to the inhabitants to go to bed. Pasquin says, it was so called, as being intended to advertise the people to secure themselves from the robberies and debaucheries of the night.

The most eminent curfew in England was that established by William the Conqueror, who appointed, under severe penalties, that, at the ringing of a bell, at eight o'clock in the evening, every one should put out their lights and fires, and go to bed: whence, to this day, a bell, rung about that time, is called a curfew-bell.

CURIA, in Roman antiquity, a certain division or portion of a tribe.

CURIO, in Roman antiquity, the chief and priest of each curia, or ward, whose business it was to officiate at the sacrifices of the curia, called *curionia*, and provide for them, the curia furnishing him with a sum of money on that consideration.

CURLEW, the English name of a bird, called by authors, *arquata* and *numenius*. See the article **NUMENIUS**.

CURNOCK, a measure of corn, containing four bushels, or half a quarter.

CURRAN, or **CURRENT**, *Ribes*, in botany, a shrub, whose bark is brown; but the extrem shoots are ash-coloured. The leaves are like those of the vine, but much less; of a dark green above, but covered with a soft down beneath. The flowers grow in bunches, and are rosaceous: and the fruit is a well known globular berry.

The red, white, and black currant, with a few others, are easily propagated by cuttings: when the leaves fall in autumn, it is the best season for planting them. They grow in good land very freely, and in three or four years will produce fruit. Great quantities of the white and red currant-trees are raised within ten miles of London, for the supply of the markets, it being looked upon as good a crop as any in general, and but little expence attending them. They are commonly planted in rows, and in autumn the ground is dug up between them, and

filled with coleworts: in the winter they should be pruned, observing to preserve the spurs which are on the old wood, and shortening the young shoots. A very little practice and observation will direct their management.

Red currants are reckoned more wholesome than the white; they are a very agreeable acid; and perhaps the most salubrious fruit that grows with us: they greatly assuage drought, cool and fortify the stomach, help digestion, excite an appetite, and are good against vomiting. But if eaten in too large quantities will cause looseness, attended with gripes, and are hurtful to the lungs.

Black currants have a very disagreeable, nauseous taste; however, a jelly is made of them, which is said to be a specific against the quinsy, if swallowed down leisurely in small quantities: it is also good to cure inflammatory disempers of the throat.

CURRENT, or **COURANT-MONEY**, that money which passes in commerce from one to another.

CURRENT, in hydrography, a stream or flux of water in any direction.

Currents, in the sea, are either natural and general, as arising from the diurnal rotation of the earth on its axis; or accidental and particular, caused by the waters being driven against promontories, or into gulphs and straits; where, wanting room to spread, they are driven back, and thus disturb the ordinary flux of the sea.

The currents are so violent under the equator, where the motion of the earth is the greatest, that they carry vessels very speedily from Africa to America; but absolutely prevent their return the same way; so that ships are forced to run as far as the 40th degree of latitude, to find a passage into Europe.

In the Straights of Gibraltar, the currents almost constantly drive to the eastward, and carry ships into the Mediterranean: they are usually, too, found to drive the same way into St. George's channel. The great violence and dangerousness of the sea in the Straights of Magellan, is attributed to two contrary currents setting in, one from the south, and the other from the north sea.

Dr. Halley makes it highly probable, that in the Downs, in the Straights of Gibraltar, &c. there are under currents, whereby as much water is carried out, as is brought in by the upper currents. This he argues from the ossing between the North and South Foreland, where it runs tide and half-tide, i. e. it is either ebb or flood in that part of the Downs three hours before it is so off at sea: a certain sign, that though the tide of flood runs aloft, yet the tide of ebb runs under-foot, i. e. close by the ground; and so at the tide of ebb it will flow under-foot.

This he confirms by an experiment in the Baltic Sound, communicated to him by an able seaman present at making it: being there, then, with one of the king's frigates, they went with their pinnae

into the mid-stream, and were carried violently by the current. Soon after that, they sunk a basket with a large cannon-bullet, to a certain depth of water, which gave check to the boat's motion; and sinking it still lower and lower, the boat was driven ahead to the windward, against the upper-current; the current aloft not being above four or five fathom deep. He added, that the lower the basket was let down, the stronger the under-current was found.

From this principle, it is easy to account for that vast draught of water continually pouring in with the current out of the Atlantic into the Mediterranean, through the freights of Gibraltar; a passage about twenty miles broad; yet without any sensible rising of the water along the coasts of Barbary, &c. or any overflowing of the lands, which there lie very low.

CURRENT, in navigation, may be defined, a certain progressive motion of the water of the sea, in several places, either quite down to the bottom, or to a certain determinate depth, by which a ship may happen to be carried forward more swiftly, or retarded, in her course, according to the direction or setting of the current, in, with, or against, the course of the ship.

The method of finding the setting and drift of a current is thus: they first fix their boat, by throwing out a triangular piece of wood, with a piece of lead fastened to it, and tied to the stem of the boat with a cord, and letting it sink sixty fathom, or more; or sometimes, by a kettle tied by the bowl, and sunk at the other: by either of these means, the boat is brought to ride as at anchor; which done, the log is hove, the glass turned, and as the log-line veers out, the drift of the log is set with the compass.

This shews whether there be any current, or none; and if any, which way it sets, and at what rate it drives, observing, however, to add something to the velocity for the boat's drift; for though she appears to stand still, yet, in reality, she is found to move. This addition experience has thus determined; if the line she rid be sixty fathom, a third part of the drift is to be added; if eighty fathom, a fourth; if an hundred, a fifth.

If a ship sail along the direction of a current, it is evident the velocity of the current must be added to that of the vessel: if her course be directly against the current, it must be subtracted; if she sails athwart the current, her motion will be compounded with that of the current, and her velocity augmented, or retarded, according to the angle of her direction with that of the direction of the current, i. e. she will proceed in the diagonal of the two lines of direction, and will describe or pass through that diagonal in the same time wherein she would have described either of the sides, by the separate forces.

Suppose a ship sails N E. 30 miles, in a current setting E S E. 20 miles, in the same time; required her true course and distance?

GEOMETRICALLY.

Having drawn the compass N E S W, (Plate XL. fig. 2.) let A be the place of the ship, and draw the N E. line A B = 30; then will B be the place the ship would have arrived at, if there had been no current. From B draw the line B C parallel to the E S E. line A C, making it equal to 20 miles, the current's drift; then will C be the ship's true place, the angle N A C her true course, and A C her true distance.

ARITHMETICALLY.

In the triangle A B C are given the side A B = 30 miles, the side B C = 20 miles, and the angle A B C = $112^{\circ} 30'$ = angle $d A c$ = distance between the S W. and E S E. lines; to find the angle B A C, and the side A C.

1. To find the angle A, it will be, As the sum of the side A B and B C = 50 — — 1.6989700
Is to their difference = 10 — — 1.0000000
So is the tangent of the half sum of } 9.8448926
the angles A and C = $33^{\circ} 45'$ }
To the tangent of half their difference = $7^{\circ} 37'$ — — } 9.1259226

Where the angle A will be = $26^{\circ} 80'$, which, being added to the angle N A B, the course steered, will give the angle N A C, or true course = $71^{\circ} 08'$ or E N E, a quarter easterly nearly.

To find the side A C, the ship's true distance, it will be, As the sine of the angle A = $26^{\circ} 08'$ — — — — 9.6490203
Is to the side B C = 20 — — 1.3010300
So is the sine of the angle B = $112^{\circ} 30'$ 9.9656153

To the side A C, the dist. required = 41.4 1.6176250

Suppose a ship, making her way good within 7 points of the wind, is bound to a port lying directly to windward or N N E, distant 100 miles, and a current under-foot setting N. by W. 45 miles in the time the ship sails 55 miles; required her true course and distance on each tack to gain her intended port, as also her distance she must fail by the log.

GEOMETRICALLY.

Having drawn the compass N E S W. (fig. 2.) let A be the place sailed from; draw the N N E. line A B equal to 100 miles, then will B represent the port the ship is bound to. Draw the lines A G, A g, at seven points distant from the wind line A B, and make each = 55 miles, the distance sailed by the log during the experiment; through G and g draw the lines G D, g d, parallel to the W. by N. line A m, the setting of the current, making each = 45 miles, the drift of the current during

the experiment, and draw the lines AD and $A d$; then will D or d , according as she failed upon the larboard or starboard tack, be the true place of the ship at the end of the experiment, or while she sails 55 miles by the log. From B draw the lines BC and $B c$, the former parallel to $A d$, and the latter parallel to AC , continuing them till they meet the lines AC and $A d$ in C and c . The problem being thus constructed, the several requisites may be measured by the line of chords and equal parts. For if the ship sails first on the larboard tack, continuing her course till she has sailed by the log the distance AH , then will her true place be C , her true course the angle NAC , and her true distance AC ; then getting her starboard tacks on board, and standing to the westward, when she has sailed by the log the distance $Cn = Ah$, she will arrive at her intended port; for then her true place will be B , her true course the angle NAC , and her true distance $BC = Ac$. But if she first sail on the starboard tack, then must she fail by the log the distance Ah , whereby her true place will be c ; then getting her larboard tacks on board, and standing to the eastward, till she has sailed by the log the distance $cp = AH$, she will arrive at her intended port; for then her true place will be B , and her true distance $cB = AC$.

ARITHMETICALLY.

3. In the oblique-angled triangle AGD are given the side $AG = 55$, the side $GD = 45$, and the angle $AGD = 67^\circ. 30'$, whence the angle GAD may be found $= 47^\circ. 40'$, and the side AD or distance sailed during the experiment $= 56.25$; and because the line AC is nearer N , than the line AG , by the angle DAG ; therefore from the angle $NAG = 101^\circ. 15'$, take the angle $DAG = 47^\circ. 40'$, the remainder $= 53^\circ. 35'$, or something more than $NE. \frac{3}{4}$ easterly, will be the true course on the larboard tack.

2. In the triangle ABC are given the angle $BAC = 22^\circ. 30'$, the angle $ACB = 91^\circ. 11'$, the angle $CBA = 57^\circ. 44'$, and the side $AB = 100$; whence the sides AC and BC , the respective distance on each tack, may be found, the former or $AC = 85.07$, and the latter or $BC = 51.64$.

To find the distance sailed by the log on each tack to gain the port.—Because the triangles ACH and ADG are similar, it will be as $AD = 56.24 : AC = 85.07 :: AG = 55 : AH = 83.1$, the distance she must sail on her larboard tack: and because the triangles $A d g$ and $A c b$ are similar, it will be, as $A d = 91 : A c = 51.64 :: Ag = 55 : Ab = 31.2 = Cn$, the distance she must sail on her starboard tack.

CURRIERS, those who dress and colour leather after it comes from the tan-yard. See the article **SKINNERS**.

CURRYING, the method of preparing leather with oil, tallow, &c.

CURSITOR, a clerk belonging to the court of chancery, whose business it is to make out original writs. In the statute 18 Edw. III. they are called clerks of course, and are twenty-four in number, making a corporation of themselves. To each of them is allowed a division of certain counties, into which they issue out the original writs required by the subject.

CURSOR, in mathematical instruments, is any small piece that slides, as the piece in an equinoctial ring-dial that slides to the day of the month; the little label of brass divided like a line of fines, and sliding in a groove along the middle of another label, representing the horizon in the analemma; and likewise a brass point screwed on the beam-compasses, which may be moved along the beam for the striking of greater or less circles.

CURTAILING, in farriery, is the docking or cutting off a horse's tail.

This practice is now where so much used as in England, it being a popular though false opinion, that the taking away the tail, makes the horse's chine or back much stronger, and more able to support a burden.

CURTAIL-DOUBLE, a musical wind instrument, like the bassoon, which plays the bass to the hautboy.

CURTAIN, or **CURTIN**, in fortification. See the article **CURTIN**.

CURTATE DISTANCE, in astronomy, the distance between the sun and that point where a perpendicular, let fall from a planet, meets the ecliptic.

CURTATION, in astronomy, is the difference between the distance of a planet in its orbit from the sun, and its distance from him when referred to the ecliptic, which is always less in the latter case than in the former.

CURTEYN, *Curtana*, in the British customs, king Edward the Confessor's sword, borne before the prince at coronations: its point is said to be broken off, as an emblem of mercy.

CURTIN, **CURTAIN**, or **COURTIN**, in fortification, is that part of the rampart of a place which is betwixt the flanks of two bastions, bordered with a parapet five feet high, behind which the soldiers stand to fire upon the covert-way and into the moat. As it is the best defended of any part of the rampart, besiegers never carry on their attacks against the curtain, but against the faces of the bastions, because of their being defended only by one flank. See the article **FLANK**.

Angle of the CURTIN, that contained between the curtain and the flank.

Complement of the CURTIN. See the article **COMPLEMENT**.

CURVATOR,

CURVATOR *Coccygis*, in anatomy, a name given by Albinus to a muscle of the coccyx, discovered by himself, and not described by any other author.

It arises with a double head, one from the inner, and the other from the lower and lateral part of the os sacrum; and descending, terminates in three extremities. He gave the name from its office, which is the bending the coccyx.

CURVATURE of a *Line*, is that peculiar manner in which it is bent, and from which it is known to be a curve of some particular property.

CURVES, in geometry, are lines continually bending in different directions, so as to admit of being cut in more places than one by a right line, and according to the number of times which this can happen; as twice, thrice, four times, &c. the curve is said to be of the first, second, third, &c. order. For if a line can but be cut once, it must of necessity be a right line, and then comes not under this denomination. It must also be observed, that as often as the above circumstance happens in any curve, so high will the dimensions of the highest power in the equation of that curve run when expressed in an algebraic manner.

The doctrine of curves, and of the figures and solids generated by them, is very extensive and intricate, and constitutes what is called the higher geometry, and into which they are divided into two sorts, algebraical, or geometrical, and transcendental. All or most of the latter kind will be more particularly treated of in this Dictionary, under their respective names, or the properties they are most remarkable for: as to the former, their number is infinite; and as every one of them require a different way of managing them, it is to no purpose to say more of them in a work of this nature.

CURVET, or **CORVET**, in the manege, an air in which the horse's legs are raised higher than the demivolt; being a kind of leap up, and a little forwards, wherein the horse raises both his fore legs at once, equally advanced, when he is going straight forward and not in a circle, and as his fore legs are falling, he immediately raises his hind legs, equally advanced, and not one before the other: so that all his four legs are in the air at once; and as he sets them down, he marks but twice with them.

CURVILINEAL, a term applied to those figures that are bounded by curve lines.

CURULE CHAIR, in Roman antiquity, a chair adorned with ivory, wherein the great magistrates of Rome had a right to sit and be carried.

CUSCUTA, dodder, in botany, a genus of plants, whose corolla consists of a single, ovated petal, a little longer than the cup, divided into four obtuse segments at the mouth: the pericarpium is fleshy, roundish, and bilocular, opening horizontally: the f. d. are two in number.

The ancients recommended it as a purge: however, we esteem it more as an attenuant and aperient in obstructions of the viscera, in jaundices, dropsies, and other chronic diseases.

CUSPS, in astronomy, the points or horns of the moon, or any other luminary.

CUSP, in astrology, the first point of each of the twelve houses, in a figure or scheme of the heavens.

CUSPIDATED PLANTS, in botany, are such plants whose leaves are pointed like a spear.

CUSPIDATED Hyperbola, that whose points concur in the angle of contact, and there terminate. See **HYPERBOLA**.

CUSTOM, a very comprehensive term, denoting the manners, ceremonies, and fashions of a people, which having turned into habit, and passed into use, obtains the force of laws; in which sense it implies such usages as, though voluntary at first, are yet, by practice, become necessary.

Custom is hence, both by lawyers and civilians, defined *lex non scripta*, a law, or right, not written, established by long usage, and the consent of our ancestors: in which sense it stands opposed to the *lex scripta*, a law, or the written law.

CUSTOM of Merchants.—If a merchant gives a character of a stranger to one who sells him goods, he may be obliged to satisfy the debt of the stranger for the goods sold, by the custom of merchants.

CUSTOMS, in commerce, the tribute or toll paid by merchants to the king, for goods exported or imported: they are otherwise called duties. See **DUTY**.

CUSTOM-HOUSE, an office established by the king's authority in maritime cities, or port towns, for the receipt and management of the customs and duties of importation and exportation, imposed on merchandises, and regulated by books of rates.

CUSTOM-OFFICERS shall not have any ships of their own, nor may they use merchandise, factorage, nor keep a tavern, &c.

CUSTOMARY TENANTS, in law, such tenants as hold by the custom of the manor, as their special evidence. These were anciently bond-men, or such as held *tenura bandagii*.

CUSTOS, in music, the same with *mostra* or index.

CUSTOS BREVIUM, the principal clerk belonging to the court of Common-pleas, whose business it is to receive and keep all the writs made returnable in that court, filing every return by itself: and at the end of each term, to receive of the prothonotaries all the records of the *Nisi Prius*, called the postea.

CUSTOS ROTULORUM, an officer who has the custody of the rolls and records of the sessions of peace, and also of the commission of the peace itself.

CUTANEOUS,

CUTANEOUS, in general, an appellation given to whatever belongs to the cutis, or skin: hence we meet with cutaneous caruncles, disorders, eruptions, &c. See the articles **CARUNCLE**, **CUTIS**, **CUTICLE**, **ITCH**, &c.

CUTICLE, *Cuticula*, in anatomy, a thin membrane, closely lying upon the skin, or cutis, of which it seems a part, and to which it adheres very firmly, being assisted by the intervention of the corpus reticulare.

CUTICULAR, the same with cutaneous. See the article **CUTANEOUS**.

CUTIS, the skin, in anatomy, the universal integument of the body, or a substance made up of several kinds of tendinous, membranous, vascular, and nervous fibres, the intertexture of which is so much the more wonderful, as it is difficult to unfold; for their directions are as various as those of the stuff of which an hat consists. This texture is what we commonly call leather, and it makes the body of the skin. It is not easily torn, may be elongated in all directions, and afterwards recovers itself: for the posterior parts of the body it is thicker and more lax than on the fore parts; and on the palms of the hands and soles of the feet, it is both very thick and very solid. It is generally more difficult to be pierced by pointed instruments in the belly than in the back.

The outer surface of this substance is furnished with small eminences, which anatomists call papillæ, in which the capillary filaments of the cutaneous nerves terminate by small radiated pencils. The greatest part of these papillæ is flat, of different breadths, and separated by sulci, which form a kind of irregular lozenges. The papillæ of the palm of the hand, sole of the foot, and of the fingers and toes, are higher than the other parts of the body; but they are likewise smaller, closely united, and placed endwise in particular rows, which represent all kinds of lines. The papillæ appear to be surrounded at their bases by a soft, mucilaginous substance, called corpus reticulare, or mucosum, which fills the interstices between them, and represents a kind of net-work, the meshes of which surround each papilla; this reticular or vascular texture is of various forms and figures in the different parts of the body.

The inner surface of the skin is covered by very small tubercles, commonly called cutaneous glands, and they are likewise termed glandulæ miliares, from their resemblance to millet seeds. These tubercles are partly fixed in small follicles, in the substance of the skin, which answer to the same number of small cavities in the corpus adiposum. Their excretory ducts open on the outer surface of the skin. The greatest part of them furnishes sweat, and others a fatty oily matter, of different thickness, which M. Morgagni calls glandulæ sebaceæ.

The late M. Duvernoy demonstrated to the Royal Academy, that the structure of some of these cutaneous glands resembled the circumvolutions of small intestines, plentifully stored with capillary vessels.

Besides these corpuscles, there are other small solid bodies, almost oval, contained in the substance of the skin; these are the roots or bulbs from whence the hairs arise.

Besides several considerable openings in the skin, it is perforated by an infinite number of small holes, called pores, which are of two kinds; some are more or less perceivable by the naked eye, such as the orifices of the milky ducts of the mammaræ, the orifices of the excretory canals of the cutaneous glands, and the passages of the hairs.

The other pores are imperceptible to the naked eye, but visible through a microscope: and their existence is likewise proved by the cutaneous transpiration, and by the effects of topical applications; and from these two phenomena they have been divided into arterial and venous pores.

There are different adhesions and folds of the skin in different parts of the body.

The outside of the skin is covered by a thin transparent web, closely joined to it, which is called epidermis, cuticula, or scarf-skin.

The substance of the cuticula appears to be very uniform on the side next the skin, and to be composed, on the other side, of a great number of very fine, small, squamous laminæ: this substance is very solid and compact, but yet capable of being extended and thickened. The origin of the epidermis is as obscure as its regeneration is evident, sudden, and surprising. The epidermis adheres very closely to the cutaneous papillæ, but still closer to the corpus reticulare; and they seem to be true portions or continuations of each other. It covers the skin through its whole extent, except at the places where the nails lie; it is marked with the same furrows and lozenges as the skin, and has the same openings and pores. The epidermis seems to insinuate itself into the small pores, in order to complete the excretory tubes of the cutaneous glands. The follicles of the hairs have likewise the same productions of the epidermis; and it seems to give a sort of coat to the hairs themselves: and lastly, the imperceptible ducts of the cutaneous pores are lined by it.

The uses of the skin are numerous: 1. To surround, cover, and defend the parts that lie underneath it. 2. To be the organ of feeling. 3. To be an universal emunctory to the body, cleansing the blood of its redundancies, by the means of sweat and perspiration; while these, at the same time, serve to prevent the acidity or dryness of the cutis itself.

CUTTER, in naval affairs, a small vessel used to navigate in the channel of England: they have

commonly one mast, and are rigged as sloops: some of these are smugglers, and some vessels in the king's service employed to catch the smugglers.

CUTTING, in heraldry, is used for the dividing a shield into two equal parts, from right to left, parallel to the horizon, or in the fesse-way.

CUTTING, in painting, the laying one strong lively colour over another, without any shade or softening. The cutting of colours hath always a disagreeable effect.

CUTTING, in surgery, the operation of extracting the stone out of the human body by section.

CUTTING in Wood, a particular kind of sculpture, or engraving, denominated from the matter whereon it is employed.

The art of cutting in wood was certainly carried to a very great height about one hundred and sixty years ago: at present it is very low in esteem, as having been long neglected, and the application of artists wholly employed on copper, as the most easy and promising province. The cutter in wood needs no other instruments than little sharp knives, chisels, and gravers of different sizes.

The first thing he does, is to take a plank or block of pear-tree, or box, which he prepares of the size and thickness intended, and makes it very even and smooth on the side to be cut: on this block he draws the design with a pen, or pencil, just as it ought to be printed. Those who cannot draw their own designs, make use of those done by another, which they fasten on the block with paste, the strokes or lines being turned towards the wood: when the paper is dry, they wash it gently over with a sponge dipped in water, which done, they take off the paper by degrees, still rubbing it a little with the tip of the finger, till there is nothing left on the block but the strokes of ink that form the design, which marks out so much of the block as is to be spared, or left standing: the rest they cut off, and take away as curiously as they can with the point of their sharp instruments.

CUTTINGS, in gardening, are branches of trees, shrubs, &c. cut off in order for their striking root, and becoming new plants: numbers of plants are raised by cuttings. Those which are deciduous and hardy, the autumn is best for this operation; but evergreen cuttings should be planted in the spring.

In providing cuttings, it is not amiss to leave a knob of the former year's wood on, particularly of those plants which grow freely. With very tender and herbaceous plants, the young branches should be cut just below the joint, and may be stuck in a pot or border, and covered air-tight with a glass; this method will greatly promote their taking root, and is done in the summer months. With some sorts it is necessary to plunge them in a moderate heat to facilitate their rooting; and it may be remarked that the young shoots of the latest growth are most proper for this operation.

CUT-WATER, in naval architecture, the foremost part of the prow of a ship, or that part which first divides the fluid. See the article **STEM**.

CYANUS, bottle-flower, in botany, a plant which grows wild in corn-fields; the stalks are angular, hollow, covered with down and branched; the lower leaves are sinuated, and not much unlike those of dandelion, but the others are narrow and long. The flower has a scaly hairy cup, and the disk almost flat, but the outer florets round the border are tubulous and deeply cut; the colour of them is generally blue, though there are varieties with other colours.

This plant is classed among the centaureys by Linnaeus.

It is said to be alexipharmic and uterine, and the water distilled from the flowers is of service in inflammations of the eyes.

CYCLAMEN, snow-bread, in botany, a genus of plants, whose flower is monopetalous; the tube is subglobose, double the size of the cup; the limb is large, and turns upwards, and is divided into five ovato-lanceolate segments; in the tube are placed five small filaments, terminated with straight pointed antheræ. The fruit is a roundish berry, opening in five parts at top, inclosing many roundish angular seeds.

The common cyclamen has a thick, orbicular, fleshy root, somewhat flattish, white within and blackish without; it has a pungent, burning, disagreeable taste. From the root arises a number of heart-shaped leaves, marked with black in the middle; these grow on foot-stalks about six or seven inches high. These flowers rise immediately from the root, with long, fleshy pedicles. When the flower falls off, their foot-stalks twist up like a screw, inclosing the germen in the center, and bends down to the ground between the leaves, which serves as a protection to the seed.

In medicine, the root is the part which is used; it is said to open and deterge very powerfully, for which reason it is recommended in the jaundice, gravel, and all obstinate obstructions. Externally it hath been used to discuss scrophulous tumours, applied in the form of a cataplasm, and for this intention its acrimony and pungency is more fitting than for internal uses.

There are other species of cyclamen, which are more tender than the above-mentioned, therefore require to be sheltered in winter with us. They are all propagated from seeds, which should be sown when ripe.

CYCLE, in chronology, a certain period, or series of years, months, days, &c. which when it has run regularly from the first to the last, returns again to the first, and thus circulates perpetually.

CYCLE of the Sun, or dominical letter cycle, is a revolution of twenty-eight years, after which interval the days of the week return on the same days.

of the month of the Julian or old style; but the reformation of the calendar, made by pope Gregory XIII. has made a sad breach in this cycle, by reducing every hundredth year, which in the Julian style was always leap year, to a common one of 365 days.

CYCLE of the Moon, or golden number, is a cycle, or period of nineteen years, after which period, the same lunar aspects, with respect to the sun, return on the same days of the month, which they did in the preceding period. The principal use of this cycle is for finding the time for observing the feast of Easter; and was established by the council of Nice, who at that time thought so highly of it as to have the numbers set down in letters of gold, from whence it had the name of the golden number.

CYCLE of Indiction, is a period of fifteen years, used by the Romans for determining the time of particular payments by the subjects of the republic, and was first founded by Constantine in the year of Christ 312.

CYCLOID, in geometry, one of the mechanical or transcendental curves: it is supposed to be generated in the following manner.

If a circle (Plate XL. fig. 3.) in a vertical position rolls along the horizontal line, AB (as the wheel of a carriage does upon the road) till it has made one revolution, that point of the circle, as A , which touched the plane, will rise up from the line, and be at a when the circle has rolled half way, having described the curve Aa , from whence (as the circle goes on) it goes downwards in the same kind of curve, till it comes to touch the line AB at B ; the point C , which was uppermost at the beginning of the motion, having been down at c when A was at a , and now being returned to k when the circle is in the same position as before its revolution began. The whole curve AaB so described is called a cycloid, and the circle AC the generating circle, and the line AB the base of the cycloid.

It is evident from the formation of the cycloid, that the base of the cycloid is equal to the circumference of the generating circle. Several other properties of the cycloid have been demonstrated by mathematicians; whose demonstrations it would be tedious to repeat here; therefore we shall take them for granted, and mention them as we have occasion for them in our conclusions about the pendulum, and other, the more particular properties and uses of this curve.

Let us now invert the cycloid, so as to have AB (fig. 4.) the base at top, and the cycloid underneath. It has been demonstrated by several, that if from any point in the cycloid, as E or p , there be drawn a line parallel to the base, and from the point where that line cuts the generating circle when it has performed half its revolution (that is, when it is at G) there be drawn a chord such as eD or qD , the in-

tercepted arc of the cycloid, as ED or pD will be double the chord eD or qD ; and so one half of the cycloid, as AD will be double the diameter GD of the generating circle. Now it has been shewn by several that a body will fall in the same time in the diameter GD , and in the chords qD , eD , a body must fall in the arcs AD pD and eD in equal times; because each of them is the double of the above-said lines GD , qD and eD ; so that when a pendulum swings in a cycloid; all the vibrations, however unequal, are isochronal.

Before we quit this subject, it may not be improper to mention a remarkable property of the cycloid, which is this, viz. that it is the line of the swiftest descent; that is, if a body is to move from A to D , there is no line of any kind which can be drawn from the upper to the lower of those points, along which a body will descend so fast as in the semi-cycloid AD ; neither an arc of a circle, nor even the straight line AD , though it be so much shorter; for the body at first setting out from A descends in so steep a direction (that is, is so much acted upon by gravity) that it acquires a great velocity, so as to carry it the more swiftly in the lower part of the curve, which is less steep: and a circular arc which would be more steep at bottom is less so at top. If an inclined line as AF , be drawn from A beyond the lowest point of the cycloid, and a body goes down that line, whilst another runs from the same point along the cycloid, the greater celerity of the body in the cycloid will appear more evidently. This property, and that of having the descent of a body from any part of the (inverted) cycloid to the bottom, exactly in the same time, will be illustrated by the following experiments.

EXPERIMENT I. Plate XL. fig. 5.

The machine $BHMD$, represented by the figure, is made of wood about ten inches high, two foot long and two inches thick. From I to F it is cut into a channel as wide at bottom as at top, in the form of a semi-cycloid inverted, the lowest point being at F , from whence the channel is continued horizontally for the length of a foot from F to G , the walls of the channel being HH and II , and this channel is very smooth and divided into two channels by a thin upright brass partition LL from the top between H and I to the farther end at G . Upon the partition are marked divisions, which from F to G are equal, but unequal from F to I , in such manner as to denote equal heights, H the beginning of the channel is nine inches above the level of E , OO are two wooden stops for the channels, and to be fixed in any place by means of a screw at the end of each of them. The whole instrument may be set upright and horizontal by means of three screws such as C , C , and the plummet NM .

Two brass balls, of half inch diameter each, are to move in the two channels.

Fix the two stops exactly at F, and the brass balls, though you let them go from different parts of their respective cycloidal channels, will strike them at the same time; which will also be very sensible to any one who holds a finger in each channel at F, whilst another person lets the balls run down from unequal heights.

Now let the stops be shifted, and one of them be fixed four inches beyond F towards G, and the other six inches beyond F; and let the two balls fall at once, the one from the height of four inches, and the other from the height of nine. That which falls from four inches in height, will go four inches beyond F; and that which falls from nine inches in height, will go six inches beyond F, each striking the obstacle in its own channel exactly in the same time as the other. Four and nine are the spaces fallen through, whose roots two and three express the respective velocities of the balls, which are shewn by one of them running four inches in the horizontal part of its channel, the other runs fix inches in the other horizontal channel.

EXPERIMENT II. Plate XL. *fig. 6.*

AECB is another machine with a cycloidal channel, wherein the whole cycloid is hollowed in from B to b, its lowest part being at C. There is a freight channel A a moveable round the point A as a center to apply on the back-side of the cycloid as the machine stands upright, so that its channel may be in the plane of any chord drawn from the point A to any part of the cycloid. Let this trough or channel be first set in the line AC; then let one of the balls fall from B in the cycloidal channel, whilst the other begins at the same time to fall from the same level in the freight channel, and you will observe, that the ball running down in the cycloid will be a good way beyond C, when the ball running in the freight channel is just got to it; as may still be made more sensible by fixing one of the stops above-mentioned (in the explanation of the last figure) over-against C in the freight channel, and the other between C and b in the cycloidal channel. If the freight channel be fixed beyond the point C as at A a, the ball in the cycloid will come from B to b and be down again at C when the other is come from A in a freight line to G.

CYCLOIDAL, of, or belonging to a cycloid.
CYCLOPÆDIA, or **ENCYCLOPÆDIA**. See **ENCYCLOPÆDIA**.

CYDER, or **CIDER**, an excellent drink made of the juice of apples, especially the more curious table kinds; the juice of these being esteemed more cordial and pleasant than that of the wild and harsh kinds.

CYGNUS. See the article **SWAN**.

CYGNUS, in astronomy, a constellation of the northern hemisphere, consisting, according to Ptolemy's catalogue, of 27 stars, Tycho's 19, and in

the British catalogue of 107; but in the following of 81.

The fabulous history of this constellation, according to the poets, is thus related. Jupiter falling in love with Læda, the wife of Tyndarus, king of Oebalia, and not knowing in what manner to satisfy his lustful desires, without exposing himself, procured Venus to transform herself into an eagle, and himself into the form of a swan; therefore flying from the eagle as from his natural enemy that earnestly pursued him, lighted in the lap of Læda, under a pretence of avoiding the eagle: Læda not knowing who it was under the shape of the swan, and consequently not fearing or apprehending any danger, went to sleep, clasping the swan in her arms close to her bosom; which opportunity Jupiter seized, and in raptures enjoyed the charms of the beautiful Læda; and in memorial of the great pleasure he received under the form of a swan, placed the figure of this bird among the stars for a constellation.

CYLINDER, in geometry, a solid supposed to be generated by the rotation of a parallelogram round one of its sides as an axis. Thus if the parallelogram ABCD (Plate XLI. fig. 1.) be supposed to

revolve round the side AD as an axis, it is manifest from the figure that it will describe the cylinder EBF C, whose altitude is equal to the length of the side AB, and the semi-diameter of its base equal to AB. If the parallelogram be a right-angled one, it is called right; but if it be otherwise, it is called a scalene one.

The most remarkable properties of the cylinder are as follow.

1. Every section parallel to the base must be a circle.

2. Every section parallel to its axis AD must be a parallelogram.

3. Every section by a plane oblique to its axis will be an ellipsis.

4. Cylinders of the same base, standing between the same parallels, are equal.

5. If the altitudes of two right cylinders be equal to the diameters of their bases, those cylinders are to one another as the cubes of the diameters of their bases.

6. Every cylinder is to its inscribed spheroid as 3 to 2.

7. Since, by the 31st article, book iv. of Pappus's Elem. Geo. the area of every circle is equal to that of a right-angled triangle, one of whose sides is equal to the radius of, or the circle, and the other a right-line equal to the circumference: therefore the superficies of every cylinder is equal to the area of a parallelogram, one of whose sides is equal to the sum of the sides AB and BC of its generating parallelogram, and the other a right-line equal to the circumference,

Therefore putting $a = AB$, $b = BC$, and $p =$ the circumference of a circle, whose radius is one, we have $pa^2 + pab =$ the superficies of the whole cylinder. And,

8. The solidity is equal to $\frac{pa^2b}{2}$ in words, equal to product of the area of the base into its altitude.

Rolling-CYLINDER, in philosophy, a cylinder which rolls upon an inclined plane.

The phenomenon of the rolling cylinder may be easily accounted for from what we have observed under CENTER of Gravity.

For let ABED (Plate XLI. fig. 2.) represent a section of a cylinder of wood, bialled on one side with a cylindric piece of lead, as B; this will bring the center of gravity out of the center of magnitude C, to some point G, between C and B. Let FH be an inclined plane, whose base is FL. It is evident the cylinder laid upon the plane will not where rest but there where a perpendicular to the horizon FL passes through the center of gravity G, and that point of the plane E, in which the cylinder touches it; and this in all angles of inclination of the plane, less than that whose sine is equal to CG, the radius being CD. This will happen in two situations

situations ABED, and *abed*; because, when the cylinder moves, the center of gravity describing a circle round the center of magnitude C, this circle will meet the perpendicular in two points G and *g*, in each of which the center of gravity being supported, the cylinder will rest: therefore the cylinder moves from E to *e* by the descent of the center of gravity from G to *g*, in the arch of the cycloid G *h g*.

If the cylinder ABED (Plate XLI. fig. 3.) inflecting on the horizontal line EL in the point E, has the center of gravity G in the horizontal diameter DB, it will gravitate in the perpendicular Ge; if therefore a plane FH touch the cylinder in the point *e*, it is plain the cylinder cannot either ascend or descend on such a plane; because G, in any situation between *e*, and H or *e*, and F, will gravitate to the left or right from the point in which the cylinder touches the plane; and so will in either case bring it back to the point *e*.

CYLINDER-CHARGE, in gunnery, that part of a great gun which is possessed by the powder and ball.

CYLINDER CONCAVE, in gunnery, is all the chace of a piece of ordnance.

It may not perhaps be amiss to take notice of the remarkable resistance in concave or hollow cylinders to that of solid ones. As for example, if this question was asked, which of two sticks equal in length, and cylindrical, is the easiest to break upon the knee, that which is entirely solid, or that which is hollow, having the same quantity of matter with the other, most people would not hesitate at all to decide that the hollow stick would be the easiest to break.

Nevertheless it is quite the contrary, as soon as we consult the principles of mechanicks. When we rest a stick upon the knee to break it, we rest it by some one of its points, and it is the point diametrically opposite, which will take a circular motion about the point of support, while the fracture is made. Here then is a lever, and this point which moves circularly, describes an arch so much the greater, as it is farther distant from the point of support, or from the fixed point, and consequently it has so much more force to resist the power, which tends to make the fracture. A thicker cylinder full is then more difficult to break, not only because it contains more matter, upon which we must act, but also because the diameter of its base is greater, and the extremity of its diameter, which moves in the fracture, is farther distant from the fixed point. If this cylinder preserving the same quantity of matter, became hollow, it is visible, that its total diameter, that is, the diameter, as well of the hollow part, as of the solid, would necessarily increase, and consequently also one of the causes, which made its force, and its resistance against being broken.

Every hollow cylinder is then stronger than a full cylinder, which has only the same quantity of mat-

ter; and this, according to all appearance, is one of the reasons why the bones of animals and the culms of corn and grass are hollow.

Galileo, the first author of these sorts of inquiries, has considered in the full and hollow cylinders, having their bases formed of the same quantity of matter, only the inequality of their diameters, and consequently he has established, that the resistance of a hollow cylinder, is to that of a full cylinder, as the total diameter of the hollow one is to the diameter of the full one.

But this consideration is imperfect in this, that the extensions of the fibres of which the cylinders are composed, are not taken in. These extensions, and consequently the resistances of all the particular fibres, continually increase from the fixed point to the most distant fibre, which must break the first, and which we may suppose in the greatest extension that it can suffer. It is the sum of all these unequal resistances that makes the resistance, which all the fibres together oppose to the power, which tends to break them.

Thus the total resistance of the cylinder depends upon three things; on the quantity of matter that composes the base; on the resistance that all these fibres together bring to their extension, and on the magnitude of the diameter of the cylinder.

There remains to determine and express geometrically these magnitudes; and it is this that M. Parent has done. The circles of the base of the full cylinders must be made equal, to the full bands or zones of the hollow cylinders, and we must find the infinite sum of the unequal resistances of all the fibres, which is a particular case of the general method of M. Varignon.

M. Parent being arrived to a general formula, which contains all the possible resistances of hollow cylinders, compared to the full, has calculated upon this formula, a table, where he supposes that the total semi-diameter of a hollow cylinder is always 100 parts; and that the resistance of the full cylinder, which contains in its base as much matter as the other, is also divided into 100 parts. We see by the table,

1. That in proportion as the hollow cylinder, of which the radius can have but 100 parts of a certain determinate magnitude, has more void, and consequently less matter, it makes a greater resistance than the correspondent full cylinder. 2. That this inequality of resistance always diminishes in proportion as the hollow cylinder is less hollow, and contains more matter; that, for example, a cylinder, of which the void is 99 radius, and 1 in thickness, and to which consequently a full cylinder answers, which is only 14 radius, has a resistance, which is to that of the full cylinder, as 848 to 100, that is, as $8\frac{72}{25}$ to 1; and that the cylinder, which has 50 in void and 50 in thickness, and to which a full cylinder of 87 radius answers, has a resistance, which

is to that of the full one, only as 121 to 100.
3. That the hollow cylinder of 99 void, the resistance of which, compared to that of the full one, which is 14 radius, would be, according to Galileo, $7\frac{1}{2}$ times greater, has one $8\frac{1}{2}$ times greater, according to the hypothesis of M. Parent, which is also that of M. Mariotte.

CYLINDER VACANT, in gunnery, is that part of the hollow that remains empty, after the gun is charged.

CYLINDRICAL, something in the form of, or resembling, a cylinder: thus we say, a cylindrical column, cylindrical compasses, mirrors, &c.

CYLINDROID, in geometry, a solid body approaching to the figure of a cylinder, but differing from it in some respect, as having the bases elliptical, but parallel and equal.

The word is formed from the Greek, *κυλινδρος*, a cylinder, and *ειδος*, resemblance.

CYMA, or **CYMATIUM**, in architecture. See **CYMATIUM**.

CYMA, in botany, the tender stalk which herbs send forth in the beginning of the spring; particularly those of the cabbage kind.

CYMATIUM, in architecture, a member, or moulding of the cornice, the profile of which is waved; that is, concave at top, and convex at bottom. See the article **CORNICHE**.

Tuscan CYMATIUM consists of an oval or quarter-round. Philander makes two Doric cymatiums, of which this is one. Baldus calls this the Lesbian atragal.

Doric CYMATIUM is a cavetto, or a cavity less than a semicircle, having its projecture subduple to its height. See article **DORIC**.

Lesbian CYMATIUM, according to Vitruvius, is what our architects otherwise call talon, viz. a concavo-convex member, having its projecture subduple to its height.

CYMBAL, *κymbalon*, a musical instrument in use among the ancients. The cymbal was round, made of brass, like our kettle-drums, and, as some think, in their form, but smaller, and of different use.

CYMBIFORME Os, a bone otherwise called naviculare. See **NAVICULARE**.

CYNANTHROPIA, in medicine, the distemper occasioned by the bite of a mad dog, wherein the patient avoids the light and every thing that is bright, and dreads the water so much, that he trembles at the sight or even the remembrance of it. See **HYDROPHOBIA**.

CYNARA, in botany, a genus of plants, whose flower is uniform, tubulated, and compound; the calyx is ventricose, and imbricated, with a number of fleshy, roundish squamas; the proper flower is hermaphrodite, monopetalous, and funnel-shaped, situated on an ovated germen, which afterwards be-

comes a single, oblong, compressed, four cornered seed, crowned with a long sessile down.

This genus includes the different species of the artichoke. See the article **ARTICHOKE**.

CYNICS, a sect of ancient philosophers, who valued themselves upon their contempt of riches and state, arts and sciences, and every thing, in short, except virtue or morality.

The Cynic philosophers owe their origin and institution to Antisthenes of Athens, a disciple of Socrates, who, being asked of what use his philosophy had been to him, replied, "It enables me to live with myself." Diogenes was the most famous of his disciples, in whose life the system of this philosophy appears in its greatest perfection: he led a most wretched life, a tub having served him for a lodging, which he rolled before him, wherever he went; yet he was, nevertheless, not the more humble on account of his ragged cloak, bag, and tub; for one day, entering Plato's house, at a time that there was a splendid entertainment there, for several persons of distinction, he jumped up upon a very rich couch, in all his dirt, saying, "I trample on the pride of Plato." "Yes," (replied Plato) but with greater pride, Diogenes." He had the utmost contempt for all the human race; for he walked the streets of Athens, at noon-day, with a lighted lantern in his hand, telling the people, "He was in search of a man." Amongst many excellent maxims of morality, he held some very pernicious opinions; for he used to say, that the uninterrupted good fortune of Harpalus, who generally passed for a thief and a robber, was a testimony against the gods. He regarded chastity and modesty as weaknesses; hence Laetius observes of him, that he did every thing openly, whether it belonged to Ceres or Venus, though he adds, that Diogenes only ran to an excess of impudence to put others out of conceit with it: but impudence was the characteristic of these philosophers, who argued, that what was right to be done might be done at all times, and in all places. The chief principle of this sect, in common with the Stoics, was, that we should follow nature; but they differed from the Stoics in their explanation of that maxim, the Cynics being of opinion that a man followed nature, that gratified his natural motions and appetites; while the Stoics understood right reason, by the word nature.

CYNIC SPASM, a kind of convulsion, wherein the patient imitates the howlings of dogs.

CYNOGLOSSUM, hound's tongue, in botany, a genus of plants, whose corolla consists of a single petal, of the length of the cup; the tube is cylindrical, and shorter than the limb, which is divided into five obtuse segments; the fruit consists of four roundish depressed capsules; the seed is single, of a oval figure, gibbous, acuminate, and smooth.

Its root is kept in the shops, and is esteemed a pectoral and narcotic.

Some recommend it in catarrhs, the gonorrhoea, and scrophulous cases.

CYNOSURA, in astronomy, a name given by the Greeks, to the constellation *ursa minor*.

This is the constellation next to the north pole.

CYNOSURUS, dog's-tail grass, in botany, a genus of plants, whose corolla consists of two valves; the exterior concave, longer, and aristated; the interior, plane, without any arista: the corolla surrounds the seed, which is single, of an oblong figure, and pointed at each end.

CYON, or **CION**, among gardeners. See the article **CION**.

CYPERUS, in botany, a genus of plants, whose flower has no corolla nor any pericarpium; the calyx is an imbricated spike with ovated squamas; it contains three short filaments, topped with oblong, sulcated antheræ; the seed is single, of a triquetrous form, acuminate, and having no villi, or hairs.

The roots of these plants are carminative and attenuant; they promote the menses, and are good in all chronic cases arising from obstructions of the viscera.

CYPHER, or **CIPHER**. See **CIPHER**.

CYPRESS, *Cupressus*, the English name of a genus of trees. See **CUPRESSUS**.

CYPRINUS, in ichthyology, a very comprehensive genus of fishes of the order of the malacopterygii, the characters of which are these: the branchiostegæ membrane on each side contains three small bones; the mouth is toothless, except that towards the orifice of the stomach there are two serrated bones which serve instead of teeth.

This is a very numerous genus, comprehending the roach, tench, carp, gudgeon, barbel, chub, bream, bleak, &c.

CYPRIPEDIUM, lady's slipper, in botany, a genus of plants, the flower of which consists of four or five very long and narrow petals; it hath ten short filaments, topped with erect antheræ. The fruit is an ovate, obtuse, three-cornered capsule, trivalvular and unilocular, which is filled with a great number of seeds.

CYRENAICS, *Cyrenaici*, a sect of ancient philosophers, so called from their founder, Aristippus of Cyrene, a disciple of Socrates.

The great principle of their doctrine was, that the supreme good of man in this life is pleasure; whereby they not only meant a privation of pain and a tranquility of mind, but an assemblage of all mental and sensual pleasures, particularly the last.

CYST, the bag, or tunic, including all incysted

tumours, as the scirrhus, atheroma, steatoma, meliceris, &c.

If in extracting an incysted tumour, the including cyst be broke, or wounded, care must be taken to remove it, otherwise the tumour will speedily return.

Indeed if the tumour be a scirrhus, sarcoma, steatoma, or in a glandular part, the contents are hard enough to make a clean extirpation of it, notwithstanding its including coats be wounded; but when the matter of the tumour is soft or fluid, by its escaping, the tumour will become flaccid, so that it will hardly be possible to make a clean extirpation of the cyst, without leaving some fragment behind, which must in that case be brought away by dressing the abscess with digestives, &c. See **ABSCESS**.

CYSTIC, a name given to two arteries and two veins, opening into the gall-bladder. The cystic arteries, *cysticæ gemellæ*, are two arteries proceeding from the right branch of the celiac; and that trunk of the vena porta which goes into the liver affords the cystic veins.

CYSTIC DUCT, *Cysticus Ductus*, a pipe that goes into the neck of the cystis, or gall bladder, into which some bilious ducts likewise open, and thro' which the greater part of the bile is evidently carried into the cystis in human subjects.

CYSTIC BILE, one of the two kinds of bile, being distinguished into the cystic and hepatic bile.

The cystic bile is very bitter, thicker, and more coloured than the hepatic.

CYSTIS, in anatomy, the same with vesicula, or bladder. See **BLADDER** and **VESICULA**.

CYTISUS, bane tree, trefoil, in botany, a genus of plants, with a papilionaceous flower, and an oblong, obtuse, and rigid pod for its fruit, wherein are a few compressed and kidney like seeds.

The leaves of cytifus are esteemed cooling and discutient.

Of this genus the laburnum is a species. See **LABURNUM**.

CZAR, a title of honour assumed by the great dukes, or, as they are now stiled, emperors of Russia.

Beckman makes no doubt but they took this title, by corruption, from cæsar, emperor; and accordingly they bear an eagle, as the symbol of their empire, and the word **CÆSAR** in their arms: yet they make a distinction between czar and cæsar, the first being taken for the king's name, and the other for the emperor's.

The first that bore this title was Basil, the son of Basilides, under whom the Russian power began to appear, about 1470.

A GENERAL DICTIONARY

OF

ARTS and SCIENCES.

D A C

D One of the letters of the alphabet, the fourth in order, and the third consonant, answering to the Hebrew Daleth, and Greek Delta.

As a numeral, D denotes 500; and with a dash over it thus, $\overline{D}$, 5000. Used as an abbreviation, it has various significations: thus, D. stands for doctor, as M. D. doctor of medicine; D. T. doctor of theology; D. D. implies doctor of divinity, or dono dedit; D. D. D. is used for dat, dicat, dedicat; and D. D. D. D. for dignum, Deo, donum, dedit.

DABAS, the name of cloths and woollen stuffs of the manufacture of Bas, in Languedoc.

DABUIS, a white cotton stuff, made in the East-Indies.

DACE, the English name of a species of cyprinus, very common in our rivers: it is longer and more slender than the roach, and has ten rays in the fin besides the anus.

DACTYL, *δακτυλος*, *Dactylus*, in ancient poetry, a metrical foot, consisting of one long and two short syllables, as *αλκίμος*, and *mürmüre*.

The dactyl and spondee are the only feet or measures used in hexameter verses; the former being esteemed more sprightly, and the latter more solemn and grave. Accordingly, where great activity is signified, we find the dactyls used with much propriety, as in the following verses of Virgil.

Quadrupedante putrem sonitu quatit ungula campum; and

Ferte citi ferrum, date tela, scandite muros.

D A F

DACTYLIC VERSES, in ancient poetry, hexameter verses ending with a dactyl. See DACTYL and HEXAMETER.

DACTYLIS, in botany, a genus of plants, whose corolla is an acute, oblong, compressed glume, and contains three capillary filaments, topped with forked antheræ. It hath no pericarpium; but the seed, which is solitary, naked, depressed on one side, and convex on the other, is included in the corolla.

DACZAJIE, silver money current in Persia, and worth five mamoudis. See the article MA-MOUDI.

DADO, in architecture, the same with the dye. See the article DYE.

DÆMON, *Δαίμων*, a name given by the ancients to certain spirits, or genii, which appeared to men, either to do them service, or to hurt them. The Platonists distinguish between gods, dæmons, and heroes. The gods are those whom Cicero call *Di majorem gentium*. The dæmons are those whom we call angels. See ANGEL.

DÆMONIAC, a word applied to a person supposed to be possessed with an evil spirit, or dæmon.

DÆMONIACS, in church history, a branch of the Anabaptists, whose distinguishing tenet is, that the devils shall be saved at the end of the world.

DAFFODIL, in botany. See the article NAR-CISSUS.

DAFFODIL-LILLY. See the article AMARYLLIS and PANCRA TIUM.

See

Sea-Daffodil. See **PANCRATIUM**.

DAILY, the same with diurnal. See the article **DIURNAL**.

DAIRY, among farmers, &c. a room or apartment where milk is kept, and manufactured into butter, cheese, &c.

The term is formed from *dey*, an old word for milk.

DAISY, *Bellis*, in botany, a genus of plants producing compound, radiated flowers. The florets which compose the disk are hermaphrodite, and those which form the rays are female. The seeds are solitary, ovated, compressed, and contained in the calyx.

From the common wild daisy are produced several varieties with double flowers and different colours, which make a pretty appearance in gardens, and are very easily propagated by parting their roots in autumn.

The leaves of the common daisy are reckoned vulnerary and diuretic.

DALECHAMPIA, in botany, a plant which grows naturally in Jamaica. Its root is composed of many fibres, from which arise several weak twining stalks, which fasten themselves to the neighbouring plants: these are furnished at each joint with a trifoliate leaf. The flowers are produced from the side of the stalk, three or four growing upon a foot-stalk: some of these are male and others female; they are small, and of an herbaceous colour. They have each a double involucre, made up of two orders of leaves, which are narrow and armed with small, bristly, stinging hairs. The flowers are succeeded by a roundish, three-cornered capsule with three cells, each containing a roundish seed.

DAM, among lawyers, signifies a boundary or confinement.

DAM, or **DYKE**. See the article **DYKE**.

DAMA, the fallow-deer, in zoology, a species of the deer-kind, distinguished by its ramble and compressed, or palmated horns.

DAMAGE, in law, in generally understood of a hurt, or hindrance attending a person's estate: but, in common law, it is a part of what the jurors are to enquire of in giving verdict for the plaintiff or defendant, in a civil action, whether real or personal; for after giving verdict on the principal cause, they are likewise asked their consciences, touching costs and damages, which contain the hindrances that one party hath suffered from the wrong done him by the other. See the article **COSTS**.

DAMARAS, an Indian taster, being a kind of armouin. See **ARMOISIN**.

DAMASK, a silk stuff, with a raised pattern, so as the right side of the damask is that which hath the flowers raised or satined.

DAMASK is also applied to a very fine steel, in some parts of the Levant, chiefly at Damascus in Syria; whence its name.

It is used for sword and cutlafs-blades, and is finely tempered. See **STEEL**.

DAMASKEENING, or **DAMASKING**, the art or operation of beautifying iron, steel, &c. by making incisions therein, and filling them up with gold and silver wire; chiefly used for adorning sword-blades, guards and gripes, locks of pistols, &c.

DAMELOPRE, a kind of bilander, used in Holland for conveying merchandise from one canal to another; being very commodious for passing under the bridges.

DAMIANISTS, in church history, a branch of the ancient Acephall heresite. They agreed with the catholics in admitting the IVth council, but disowned any distinctions of persons in the Godhead, and professed one single nature, incapable of any difference; and yet they called God, the Father, Son, and Holy Ghost.

DAMPS, in natural history, noxious steams and exhalations, frequently found in mines, pits, wells, and other subterraneous places.

DAMSON-TREE. See the article **PRUMUS**.

DAMNATA TERRA, among chemists, the same with *caput mortuum*. See the article **CAPUT**.

DANCE, an agreeable motion of the body, adjusted by art to the measures or tune of instruments, or of the voice.

DANCETTE, in heraldry, is when the outline of any bordure, or ordinary, is indented very largely, the largeness of the indentures being the only thing that distinguishes it from indented. See the article **INDENTED**.

DANCHE, in heraldry, the same with *dentelle*, according to Guillim: but Columbiere makes it the same with indented.

DANDELION, *leontodon*, in botany, a plant whose flowers are compound and imbricated. The florets are monopetalous and ligulated, and contain five short capillary stamina. The seed, which is solitary and oblong, is contained in the cup of each of the corollae, and topped with down.

This plant grows naturally in fields; and is a very troublesome weed in gardens.

In medicine, it is accounted an aperient and hepatic: and Boerhaave is of opinion, that when it is used for a considerable time, it will dissolve almost all kinds of coagulations, and open the most obstinate obstructions of the viscera.

When this plant is young, it is by many people eaten as a salad, and particularly among the French.

DANEGETL, a tax, or tribute, on every hide of land, imposed on our ancestors the Saxons by the Danes, on their frequent invasions, as the arbitrary

trary terms of peace and departure. It was first imposed as a continual yearly tax upon the whole nation, under king Ethelred. It was levied by William I. and II. but was released by king Henry the First; and finally abolished by king Stephen.

DANK, a piece of silver current in Persia, and some parts of Arabia, weighing the sixteenth part of a drachm. It is also a weight used by the Arabians to weigh jewels and drugs.

DANTELE, in heraldry, the same with dancette.

DAPHNE, in botany, a genus of plants, the flower of which consists of a single petal; the tube is cylindric, imperforated, and longer than the limb, which is divided into four oval, acute, plane, patent segments: the fruit is a roundish berry, containing one cell; the seed is single, round, and fleshy.

DAPIFER, the dignity or office of grand-master of a prince's household. This title was given by the emperor of Constantinople to the czar of Russia, as a testimony of favour. In France the like office was instituted by Charlemaign, under the title of dapiferat; and the dignity of dapifer is still subsisting in Germany, the elector of Bavaria assuming the title of arch-dapifer of the empire, whose office is, at the coronation of the emperor, to carry the first dish of meat to table, on horse-back.

DAPPLE BAY, in the manege; when bay horses have marks of a dark bay, they are called dapple-bays.

DAPPLE-BLACK, when a black horse has got spots or marks more black or shining than the rest of his skin, he is called a dapple black.

DARAPTI, among logicians, one of the modes of syllogisms of the third figure, whose premises are universal affirmatives, and the conclusion is a particular affirmative: thus,

- DAR- Every body is divisible;
- AP- Every body is a substance;
- TI- Therefore, some substance is divisible.

DARII, in logic, one of the modes of syllogisms of the first figure, wherein the major proposition is an universal affirmative, and the minor and conclusion particular affirmatives: thus,

- DA- Every thing that is moved, is moved by another.
- RI- Some body is moved;
- I- Therefore, some body is moved by another.

DARNEL, the English name of the lolium of botanists. See the article **LOLIUM**.

DART, in astronomy, geometry, &c. See the article **SAGITTA**.

DATA, among mathematicians, a term for such things or quantities as are given or known, in or-

der to find other things thereby that are unknown. Euclid uses the word data, of which he hath a particular tract, for such spaces, lines, and angles, as are given in magnitude, or to which we can assign others equal.

In algebra the given quantities, or data, are generally expressed by the first letters of the alphabet, and the unknown by the last letters; thus, if the problem be, From the sum and product of two quantities given, to find the quantities themselves, the quantities are represented by y and z ; and $y + z = a$, the sum given, and $yz = b$, the product given. See the article **EQUATION**.

DATA also expresses, in philosophy and medicine, any quantity, which for the sake of a present calculation is taken for granted to be such, without requiring an immediate proof for its certainty, called also the given quantity, number, or power.

DATE, in law, is the description of the day, month, year of our Lord, and year of the reign of the king, in which a deed or other writing was made. Anciently deeds had no dates but only of the month and year, and now, if in the date of any deed, the year of our Lord is right, though the year of the king's reign be wrong, it shall not hurt the same.

An antedate is a date prior to the real time when the instrument was passed.

DATE, the fruit of the phoenix, or great palm-tree. See **PHOENIX**.

DATISI, in logic, a mode of syllogisms in the third figure, wherein the major is an universal affirmative, and the minor and conclusion particularly affirmative propositions. For example,

- DA- All who serve God are kings;
- TI- Some who serve God are poor;
- SI- Therefore some who are poor are kings.

DATIVE, among grammarians, the third case in the declension of nouns, expressing the relation of a thing to whose profit or loss some other thing is referred. It is called dative, because usually governed by a verb, implying something to be given to some person. In English, the dative is expressed by the signs *to* or *for*.

DATURA, thorn-apple, in botany, a genus of plants whose flower is monopetalous and funnel-shaped, with five subulated filaments, topped with oblong compressed antheræ. The fruit is an oval, bilocular, prickly capsule; and contains a number of kidney-shaped seeds. The common thorn-apple is annual, and grows to the height of two feet. The leaves are large, angular pointed, and of a deep colour, with a very offensive fœtid smell.

It flowers in July and August: and is a poisonous plant; taken inwardly, it causes vomiting, madness, convulsions, which are succeeded by death, if immediate help is wanting.

DAY

This genus is the same with the *stramonium* of Tournefort.

DAUCUS, carrot, in botany. See the article **CARROT**.

DAVIDISTS, in church history, a sect of Christian heretics in the sixteenth century; so called from David George, their leader, who began by giving out that he was the Messiah, and was sent into the world in order to people the kingdom of Heaven, which was quite empty of inhabitants, for want of virtuous and good men: he rejected marriage, and denied the resurrection.

DAVIS'S QUADRANT. See **QUADRANT**.

DAVIT, in naval affairs, a long beam of wood thrust out across from over the ship's fore-castle to draw up the flocks of the anchor clear from the ship's side.

The davit is occasionally shifted to project over either side of the ship's fore-part, or, in the sea-language, over either bow. Its inner end is secured by a strong ring or link of iron, placed in the middle of the fore-castle, called the span-shackle; and over the outer-end, which has a notch cut round it for that purpose, is hung a strong block called the fish-block, through which is inserted a rope called the fish-pendant, which being hooked to the flocks of the anchor, immediately draws them up by a tackle or complication of pulleys, as soon as the anchor is catted. See the article **CAT**.

DAUPHIN, a title given to the eldest son of France, and heir presumptive of the crown, on account of the province of Dauphiny, which, in 1343, was given to Philip of Valois, on this condition, by Humbert, dauphin of the Viennois.

DAY, according to the most natural and obvious sense of the word, signifies that space of time during which it continues to be light; in contradistinction to night, being that partition of time wherein it is dark; but the space of time in which it is light, being somewhat vague and indeterminate, the time between the rising and the setting of the sun is usually looked on as the day; and the time which lapses from its setting to its rising again, the night.

The word day is often taken in a large sense, so as to include the night also; or to denote the time of a whole apparent revolution of the sun round the earth, in which sense it is called by some a natural day, and by others an artificial one: but to avoid confusion, it is usual to call it in the former sense simply the day, and in the latter a *nychthemeron*, by which term that acceptation of it is aptly denoted, as it implies both day and night.

The *nychthemeron* is divided into twenty-four parts, called hours, which are of two sorts, equal and unequal, or temporary. See the article **HOUR**.

Different nations begin their day at a different hour: thus the Egyptians began their day at midnight, from whom Hippocrates introduced that way of reckoning into astronomy, and Copernicus and

DAY

others have followed him: but the greatest part of astronomers reckon the day to begin at noon, and so count twenty-four hours, till the noon of the next day; and not twice twelve, according to the vulgar computation. The method of beginning the day at midnight prevails also in Great-Britain, France, Spain, and most parts of Europe.

The Babylonians began their day at sun-rising, reckoning the hour immediately before its rising again the twenty-fourth hour of the day, from whence the hours reckoned in this way are called the *Babylonic*. In several parts of Germany, they begin their day at sun-setting, and reckon on till it sets next day, calling that the twenty-fourth hour: these are generally termed *Italian hours*. The Jews also began their *nychthemeron* at sun-setting; but then they divided it into twice twelve hours, as we do, reckoning twelve for the day, be it long or short, and twelve for the night; so that their hours continually varying with the day and night, the hours of the day were longer than that of the night, for one half year, and the contrary the other, from whence their hours are called temporary: those at the time of the equinoxes became equal, because then those of the day and night are so. The Romans also reckoned their hours after this manner, as do the Turks at this day.

This kind of hours are called *planetary*, because the seven planets were anciently looked upon as presiding over the affairs of the world, and to take it by turns each of these hours, according to the following order: Saturn first, then Jupiter, Mars, the sun, Venus, Mercury, and last of all the moon: hence they denominated each day of the week from that planet whose turn it was to preside the first hour of the *nychthemeron*. Thus assigning the first hour of Saturday to Saturn, the second will fall to Jupiter, the third to Mars, and so the twenty-second of the same *nychthemeron* will fall to Saturn again, and therefore the twenty-third to Jupiter, and the last to Mars: so that on the first hour of the next day, it will fall to the sun to preside; and by the like manner of reckoning, the first hour of the next will fall to the moon; of the next, to Mars; of the next, to Mercury; of the next, to Venus: hence the days of the week came to be distinguished by the Latin names of *Dies Saturni, Solis, Lunæ, Martis, Mercurii, Jovis, and Veneris*; and among us, by the names of Saturday, Sunday, Monday, &c.

DAY-LILY, in botany. See the article **HEMEROCALLIS**.

DAYS of Grace, are those granted by the court at the prayer of the defendant, or plaintiff, in whose delay it is.

DAYS of Grace, in commerce, are a customary number of days allowed for the payment of a bill of exchange, &c. after the same becomes due.

Three days of grace are allowed in England; ten in France and Dantzic; eight at Naples; six at Venice, Amsterdam, Rotterdam, and Antwerp: four

four at Frankfort; five at Leipzig; twelve at Ham-
burgh; six in Portugal; fourteen in Spain; thirty
in Genoa, &c.

DAYS MAN, in the north of England, an arbi-
trator or person chosen to determine an affair in
dispute.

Dog-DAYS, *Dies Caniculares* See the article
CANICULAR DAYS.

Intercalary DAYS. See the article **INTERCA-
LARY DAYS**.

DAY COAL, among miners, an appellation given
to the upper stratum of the coal, or that which lies
next the surface of the earth.

DEACON, *διακονος*, one of the three sacred
orders of the Christian church. The word is some-
times used in the New Testament for any one that
ministers in the service of God, in which sense
bishops and presbyters are styled deacons; but in its
restrained sense, it is taken for the third order of the
clergy, as appears from the concurrent testimony of
ancient writers, who constantly stile them ministers
of the mysteries of Christ, ministers of episcopacy
and the church, and the like. The first institution
of this order is recorded in Acts, chap. vi.

DEACONESS, *a Female Deacon*, an order of
women, who had their distinct offices and services
in the primitive church.

DEAD, in general, something void or deprived
of life. See **DEATH**.

DEAD-EYES, in naval affairs, certain blocks
with three holes in them, whereby to draw tight the
shrouds and stays of a ship.

In order to form the purchase which tightens the
shrouds, &c. there are always two of these dead-eyes
placed at small distances from each other, one in the
end of the shroud, and the other to the ship's side,
by a strop or link of iron encompassing the edge of
it; then a smaller rope, called the laniard, is passed
alternately through the holes in the upper and lower
dead-eyes, and drawn tight by the application of a
tackle. See **CHANNEL** and **CHAINS**.

The dead-eyes used for the stays have only one
hole in them, and are more usually termed hearts.

There are likewise dead-eyes of another form used
for the crow-feet: these are long, inclining to round,
and tapering to one end. See **CROW-FEET**.

DEAD-LIGHT, amongst seamen, a sort of strong
wooden posts, made exactly to fit the cabin-windows:
they are always fixed in on any expectation of a
storm, and the glass windows taken out, which might
otherwise be shattered to pieces by the sea, and let
great quantities of water pour into the ship.

DEAD-NETTLE, the English name for the lam-
ium of botanists. See **LAMUM**.

DEAD-RECKONING, in navigation, the judgment
or estimation which is made of the place where a
ship is, without any observation of the heavenly
bodies; and is performed by keeping an account of
her way by the log, in knowing the course they have

steered by the compass, and by rectifying all the al-
lowances for drift, lee-way, &c. according to the
ship's known trim. This reckoning, however, is
always to be corrected as often as any good observa-
tion can be obtained.

DEAD-RISING, or **RISING-FLOOR**, in ship-
building, those parts of a ship's floor afore and a-
baft, where it begins to rise and grow narrower as
it approaches the stem and stern-post.

DEAD-TOPS, a disease incident to young trees,
cured by cutting off the dead parts close to the next
good twig or shoot, and claying them over, as in
grafting. See the article **GRAFTING**.

DEAD-WATER, in the sea language, the eddy
of water which closes in with a ship's stern, as the
falls through it.

DEADLY-CARROT, a plant called by botanists
thapsia. See the article **THAPSIA**.

DEADLY-NIGHTSHADE, in botany. See the
article **ATROPA**.

DEAFFORESTED, a term found in law-books,
signifying that a place is discharged from being a
forest, or freed from the forest-laws.

DEAFNESS, the state of a person who either
wants the sense of hearing, or has it greatly im-
paired.

With regard to the cure, if the obstruction be in
the external cavity of the ear, it is discernible by the
sight. If there is occasion to syringe the ear, a decoction of sage and rosemary-flowers will be proper,
with equal parts of water and white-wine: but great
caution should be used.

Hoffman says, deafness sometimes arises from a
slackness of the auditory nerves, which often hap-
pens from too great a humidity, which, if neglected,
will terminate in a perpetual and incurable deafness,
and may be dispersed, if taken in time, by proper
cephalics and sudorifics.

Heister informs us, that medicinal waters drank in
the summer-time pretty largely, are the best means
as preservatives, and for curing disorders of the ears;
and that they often perform more than any other
remedies whatever.

DEAL, a thin kind of fir-planks, of great use
in carpentry: they are formed by sawing the trunk
of a tree into a great many longitudinal divisions, of
more or less thickness, according to the purposes
they are intended to serve.

Deals are rendered much harder, by throwing
them into salt-water as soon as they are sawed,
keeping them there three or four days, and after-
wards drying them in the air or sun; but neither
this, nor any other method yet known, will preserve
them from shrinking.

DEAN, an ecclesiastical dignity in cathedral and
collegiate churches, and head of the chapter.

Rural DEAN, called also archpresbyter, origi-
nally exercised jurisdiction over ten churches in the
country, and afterwards became only the bishop's
substitute.

substitute, to grant letters of administration, probate of wills, &c. to convocate the clergy, and signify to them sometimes by letters, the bishop's will, and to give induction for the archdeacon. Their office is now lost in that of the archdeacons and chancellors.

DEAN of a *Monastery*, was a superior established under the abbot, to ease him in taking care of ten monks; whence he was called decanus.

DEAN and **CHAPTER**, are the bishop's council to assist him in the affairs of religion, and to assist to every grant which the bishop shall make to bind his successors. As a deanery is a spiritual dignity, a man cannot be a dean and prebendary of the same church.

DEARTHULATION, the same with diarthrosis. See the article **DIARTHROSIS**.

DEATH, *Mors*, is generally considered as the separation of the soul from the body; in which sense it stands opposed to life, which consists in the union thereof.

DEATH-WATCH, in zoology, an insect nearly of the size of the common louse, frequent among old wood, furniture, &c. It is of an oblong and flatish figure, and of a pale brownish white colour; and the noise, resembling the beating of a watch, is the love note of these animals, when the male or female woo each other.

DE BENE ESSE, a Latin phrase used in our law in a doubtful meaning, as to take or do a thing *de bene esse*, is to allow it at present to be well done; but when it comes to be more fully examined, then to stand or fall, according to the merit of the thing.

DEBENTURE, a term of trade used at the custom-house for a kind of certificate signed by the officers of the customs, which intitles a merchant exporting goods to the receipt of a bounty or drawback.

DEBENTURE, in some of the acts of parliament, denotes a kind of bond or bill first given in 1649, whereby the government is charged to pay the soldier creditor, or his assigns, the money due on auditing the account of his arrears.

DEBENTURE is likewise used in the exchequer, and given to the king's servants for the payment of their wages.

DEBET, among merchants, signifies the sums due to them for goods sold on credit, for which they have charged their journal or ledger. It is more particularly understood of the remainder of debts, part of which has been paid on account.

DEBET, among book-keepers, is used to express the left-hand page of the ledger, to which are carried all articles supplied or paid on the subject of an account.

DEBILITY, among physicians, a relaxation of the solids, occasioning oftentimes weakness and faintings.

DEBRUIZED, in heraldry, a term peculiar to the English, by which is intimated the grievous restraint of any animal, debarred of its natural freedom, by any of the ordinaries being laid over it.

DEBT, *Debitum*, in law, any thing due to another, whether it be money, goods, or services; or the action brought for recovering the same.

DEBTOR, a person who owes any thing to another, in contradistinction to creditor, which is he to whom the debt is owing.

DEBTOR, in merchant's accounts. See **BOOK-KEEPING**.

DECACHORDON, in antiquity, a musical instrument with ten strings, called by the Hebrews, *halsur*, being almost the same as our harp, of a triangular figure, with an hollow belly, and sounding from the lower part.

DECAGYNIA, the name of an order, or subdivision in the Linnæan system of botany, and comprehends such flowers as have ten pistils or styles in each.

DECAGON, a plane figure in geometry, having ten sides and ten angles; and if all the sides are equal, and all the angles, it is called a regular decagon, and may be inscribed in a circle.

The word is formed from the Greek, *δεκα*, ten, and *γωνια*, an angle.

The sides of a regular decagon are, in power and length, equal to the greatest segment of an hexagon inscribed in the same circle, and cut in extreme and mean proportion.

DECALOGUE, the ten precepts or commandments delivered by God to Moses, after engraving them on two tables of stone.

The word is Greek, *δεκαλογος*, and compounded of *δεκα*, ten, and *λογος*, a word.

The Jews, by way of excellence, call these commandments the ten words, from whence they had afterwards the name of decalogue.

DECAMPING, in military affairs, is the marching of an army from the ground where it before lay encamped. See **CAMP**.

DECANDRIA, the name of the tenth class in the Linnæan system of botany; its characteristic is, that it consists of such plants as bear hermaphrodite flowers, furnished with ten stamina in each.

To this class belong saxifrage, dittany, arbutus, lychnis, and several others.

DECANTATION, among chemists, &c. the gently pouring off a liquor from its feces, by inclining the lip, or canthus of the vessel; whence the name.

DECANUS, in Roman antiquity, an officer who presided over ten other officers, and was head of the contubernium, or serjeant of a file of soldiers.

DECAPITE, or **DEFAIT**, in heraldry. See the article **DEFAIT**.

DECASTYLE, in the ancient architecture, a building with an ordonnance of ten columns in front, as the temple of Jupiter Olympius was.

DECEIT, *Dolus*, in law, a subtle trick, or device, to which may be added all manner of craft and collusion, or underhand practice, used to defraud another, by any means whatever.

DECEMBER, in chronology, the last month of the year, consisting of thirty-one days, and so called, as being the tenth month in the Roman year, which commenced with March. See the articles **YEAR** and **MONTH**.

DECEMVIRI, in Roman antiquity, ten magistrates chosen annually at Rome, to govern the commonwealth instead of consuls, with an absolute power to draw up and make laws for the people.

There were also other decemviri, created on frequent emergencies, to manage and regulate certain affairs, as conducting colonies, presiding at feasts, taking care of sacrifices, keeping the sybils books, &c.

DECENNALIA, ancient Roman festivals celebrated by the emperors, every tenth year of their reign, with sacrifices, games, and largesses for the people.

DECENNIERS, **DECINERS**, or **DOZINERS**, in our ancient law, such as had the oversight of ten friburghs, for the maintenance of the king's peace, the limits of whose jurisdiction was called decenna.

DECIDUOUS, an appellation chiefly used in respect to plants: thus, the calyx or cup of a flower is said to be deciduous, when it falls along with the flower-petals; and, on the contrary, it is called permanent, when it remains after they are fallen. Again, deciduous leaves are those which fall in autumn, in contradistinction to those of ever-greens, which remain all the winter.

DECIL, in astronomy, an aspect or position of two planets, when they are distant from each other a tenth part of the zodiac.

DECIMAL ARITHMETIC, the art of computing by decimal fractions, first invented by Johannes Regiomontanus, and used by him in the construction of his tables of sines.

DECIMAL FRACTIONS are those whose denominator is 1, with one or more cyphers; as, 10, 100, 1000, 10000, &c. Thus, $\frac{1}{10}$, $\frac{1}{100}$, $\frac{1}{1000}$, &c. are decimal fractions.

DECIMATION, a punishment inflicted by the Romans on such soldiers as quitted their post, or behaved themselves cowardly in the field. The names of all the guilty were put into an urn or helmet, and as many were drawn out as made the tenth part of the whole number, and these were put to the sword, and the others saved.

DECIPHERING, the art of finding the alphabet of a cipher. See **CIPHER**.

DECKS, in ship-building, the planked floors on which the guns rest and the men walk: they are supported by the beams, and by two rows of small pillars called stanchions, situated at proper distances from each other for the whole length of the ship. First and second rate ships, and the largest order of the third rate, are furnished with three decks, distinguished by the names of the upper, middle, and lower-decks, the last of which is however commonly termed, absurdly enough, the gun-deck: besides these three, there is the quarter-deck and fore-castle, which are on the same line, but are at some distance from each other, leaving a vacancy in the middle, which is called the waist. Above the hinder or almost part of the quarter-deck there is yet another deck, called the poop, which extends nearly over half of the quarter-deck, and forms a roof for the captain's cabin, which is called the coach.

Flush-Deck, or a *DECK flush fore and aft*, is one laid from stem to stern, with one floor, without any heights or hollows, only the gradual rising of the floor from the middle towards the two ends.

DECLAMATION, a speech made in public, in the tone and manner of an oration, uniting the expression of action to the propriety of pronunciation, in order to give the sentiment its full impression upon the mind.

DECLARATION, in law, is a formal shewing in writing the ground of complaint of the plaintiff, in an action against the defendant, where the plaintiff is supposed to have received some injury.

DECLENSION, in grammar, an inflexion of nouns, according to their divers cases, as nominative, genitive, dative, &c. It is a different thing in the modern languages, which have not properly any cases, from what it is in the ancient Greek and Latin.

DECLINATION, in astronomy, is the distance of any celestial object, or point in the heavens, from the celestial equinoctial, either north or south, in degrees, minutes, &c. measured on a meridian, or circle of declination.

The greatest declination of the sun, or of the ecliptic, was first, as we know of, observed by Pytheas, at Massilia, about 324 years before Christ; who, observing that the height of a gnomon was to its shadow, when the sun was in the meridian, as 31951 $\frac{1}{2}$ to 90000, from thence concluded the sun's greatest declination to be 23 deg. 52 min. 41 sec. And Gassendus found the solstitial shadow of the same length as it had been observed by Pytheas, near 2000 years before: and so he concluded that the sun's greatest declination is constant. But from a comparison of the several observations concerning this matter, the sun's greatest declination is commonly accounted 23 deg. 30 min.

DECLINATION of the Sea-Compass, or Needle, is its variation from the true meridian of any place.

DECLINATION of a Wall, or Plane of Dials, is an arch of the horizon, contained either between the plane and the prime vertical circle, if you reckon it from the east or west; or else between the meridian and the plane, if you account it from the north or south.

DECLINATORIES, are instruments for taking the declinations, inclinations, and reclinations of planes; and they are of several kinds.

The best sort for taking the declination consists of a square piece of brass, or wood, with a limb accurately divided into degrees, and every fifth minute, if possible, having a horizontal dial moving on the center, made for the latitude of the place it is to serve in, and which has a small bit of fine brass fixed on its meridian line, like a fiducial edge, to cut the degrees of the limb; for at any time when the sun shines, by having the hour of the day, you may find the declination of any wall or plane by this instrument.

DECLINING DIALS, are those whose planes stand perpendicularly to the horizon, and decline; that is, do not face directly the four cardinal points. See the article **DIAL**.

DECLIVIS, in anatomy, a muscle otherwise called obliquus descendens. See the article **OBLIQUUS**.

DECLIVITY, denotes just the reverse of acclivity. See **ACCLIVITY**.

DECOCTION, in pharmacy, the boiling simples, or other drugs, in order to extract their virtues for some medicinal purpose.

DECOMPOSITE LEAF, one whose petiole is twice divided before it gives rise to the leaf.

DECOMPOSITION, in chemistry and pharmacy, the reduction of a body into its principles or component parts. See the article **ANALYSIS**.

DECORATION, in architecture, is used for whatever adorns a building, either without-side, or within. The orders of architecture contribute a great deal to the decoration; but then the several parts of these orders must have their just proportion, characters, and ornaments, otherwise the finest order will bring confusion rather than richness.

DECORTICATION, the same with barking of trees. See **BARKING**.

DECORUM, in architecture, is the suitableness of a building, and the several parts and ornaments thereof, to the station and occasion.

DECOUPLE, in heraldry, the same as uncoupled: thus, a chevron decouple, is a chevron wanting so much of it towards the point, that the two ends stand at a distance from one another, being parted and uncoupled.

DECOY. In a naval chace, it is usual for small ships of war to disguise themselves in such a man-

ner by painting, as to be mistaken for merchantmen, or ships of the enemy, in order to deceive and provoke the adversary to chase, at which time they are careful, by altering the trim of the ship, which is easily done, to prevent her from sailing fast, although at the same time they have a great sail abroad, and appear extremely anxious to escape.

DECOY, a place made for catching wild fowl. Hence,

DECOY-DUCK is a duck that flies abroad, and lights into company of wild ones, which by her allurements she draws into the decoy.

DECREE, an order made by a superior power for the regulation of an inferior.

DECREE, in the civil law, is a determination that the emperor pronounces upon hearing a particular cause between the plaintiff and defendant.

DECREEES of Councils, are the laws made by them, to regulate the doctrine and policy of the church.

DECREEES in Chancery, are the determinations of the lord-chancellor, upon a full hearing of the merits of a cause.

DECREET, in the law of Scotland, a final decree or judgment of the lords of session, from which an appeal only lies to parliament.

DECREMENT, in heraldry, signifies the wane of the moon from the full to the new.

DECREPITATION, in chemistry, the act of calcining salt over the fire, till it ceases to crackle. The design of this is to free the salt from superfluous moisture: but as it is thereby rendered porous, and apt to imbibe the humidity of the air, it must always be kept very close afterwards, lest the air should moisten it a-new.

DECREPITATION is also applied to the crackling of the salts during the operation.

DECRETAL, in the canon-law, a letter of a pope, determining some point or question in the ecclesiastical law. The decretals compose the second part of the canon-law.

DECUPLE PROPORTION, that of ten to one: See the article **PROPORTION**.

DECURIO, in Roman antiquity, a commander of ten men in the army, or the chief of a decury.

DECURRENT LEAF, one which adheres immediately to the stalk of a plant, without any petiole, and which has its lower part extended, and running a little way along the branch.

DECURY, ten persons ranged under one chief, or leader, called the decurio.

DECUSSATION, a term in geometry, optics, and anatomy, signifying the crossing of any two lines, rays, or nerves, when they meet in a point, and then go on separately from one another.

DECUSSORIUM, a surgeon's instrument, which, by pressing gently on the dura mater, causes

DEF

causes an evacuation of the pus collected between the cranium and the before-mentioned membrane, through the perforation made by the trepan.

DEDICATION, a solemn devoting, or setting apart, any person or thing, to the service of God, and the purposes of religion.

DEDICATION, in matters of literature, the inscribing a book, poem, play, or the like, to some person of distinction, serving both as a protection and honour to them, and a mark of the author's respect for the person to whom he dedicates his work.

DEDUCTION, in commerce, a subtracting or retrenching a little sum paid, from a greater remaining yet unpaid.

DEDUCTIONE, in music, a name given to the rising of the voice, in pronouncing the syllables *ut, re, mi, fa, sol, la*; *quia per has deducitur vox*; in contradistinction to *reductio*, when the voice descends by these, *la, sol, fa, mi, re, ut*; *quia per has reductur vox*.

DEED, an instrument written on paper or parchment, comprehending some contract, bargain, or agreement, between the parties thereto, in relation to the matter therein contained.

DEER, *Cervus*, in zoology. See the article **CERVUS**.

DEER-HAYS, large nets, made of cords, to catch deer. Whoever keeps them, except in his own park, forfeits forty shillings a month.

DEER-STEALERS are punishable by various laws and statutes, made from time to time. Any offender convicted of deer-stealing, before a judge of goal delivery, may be transported by 5 Geo. I. cap. xxviii. And it is felony for persons to appear armed and disguised in a forest or park, and hunt or kill the deer, by 6 Geo. I. cap. xxii.

DE FACTO, something actually in fact, or existing, in contradistinction to *de jure*, where a thing is only so in justice, but not in fact: as a king *de facto* is a person that is in actual possession of a crown, but has no legal right to the same; and a king *de jure* is the person who has a just right to the crown, though he is out of possession thereof.

DEFAMATION, the speaking slanderous words of another; for which the slanderer is punishable, according to the nature of his offence, either by action upon the case at common law, or by statute, or in the ecclesiastical court. No damages are given in the ecclesiastical court, but the punishment of the party is by way of penance.

DEFAULT, in law, is generally taken for non-appearance in court, at a day assigned; but imports any omission of that which we ought to do, for which judgment may be given against the defaulter. In the usual sense, if the plaintiff in a suit make default in appearance on a trial, he will be non-suited; and where a defendant makes default, judgment should be had against him by default. Jurors

DEF

making default in their appearance, are to lose and forfeit issues.

DEFECTIVE, in general, an appellation given to things which want some of the properties that naturally they ought to have. Thus,

DEFECTIVE NOUNS are those which want one of the numbers, or one or more cases. See the article **NOUN**.

DEFECTIVE THIRD, among musicians, the same with diminished third. See the article **DIMINISHED**.

DEFEISANCE, or **DEFEASANCE**, in our law, a condition relating to some certain deed, which being performed, the deed is defeated and rendered void, as if it had never been made.

DEFENCE, in fortification, all sorts of work that cover and defend the opposite posts; as flanks, casemats, parapets, and faussebrays.

It is almost impossible to fix the miner to the face of a bastion, till the defences of the opposite one are ruined, that is, till the parapet of its flank is beaten down, and the cannon, in all parts that can fire upon that face which is attacked, are dismounted.

Line of DEFENCE, a supposed line drawn from the angle of the curtain, or from any other part in the curtain, to the flanked angle of the opposite bastion. See the articles **CURTAIN** and **BASTION**.

A line of defence represents the flight of a musket-ball from the place where the musketeers stand, to scour the face of the bastion, and ought never to exceed the reach of a musket. It is either *sichant* or *razant*; the first is when it is drawn from the angle of the curtain to the flanked angle: the last, when it is drawn from a point in the curtain, razing the face of the bastion.

DEFENCE, in law, signifies a plea, or what the defendant ought to make after the plaintiff's count, or declaration, viz. that he defends all the wrong, force, and damages, where and when he ought, &c.

DEFENCES, in heraldry, are the weapons of any beast, as the horns of a stag, the tusks of a wild boar, &c.

DEFENDANT, in law, the person sued in an action personal; as tenant is he who is sued in an action real. See **ACTION**.

DEFENDER of the Faith, a peculiar title, belonging to the king of Great-Britain, as Catholic does to the king of Spain, Christian to the king of France, &c.

This title was first given by pope Leo X. to king Henry VIII. for writing against Luther.

DEFENSITIVE, in surgery, signifies a bandage, plaster, &c. to defend any part from external injuries.

DEFERENT, in anatomy, a term applied to certain vessels in the body, that serve for the conveyance

veyance of humours from one part to another. See *DEFERENTIA VASA*.

DEFERENT, in the Ptolemaic astronomy, a circle invented to account for the eccentricity, perigee, and apogee of the planets.

DEFERENTIA VASA, two white, solid, flattened tubes, one lying on the right side, the other on the left, from the epididymis, of which they are continuations: each of them runs up in the cellular vagina of the spermatic vessels, as high as the openings in the abdominal muscles; the blood vessels lying forward, and the vas deferens behind them.

Their use is to carry the semen from the epididymes to the vesiculæ seminales; and, in the coitus, to discharge it into the urethra.

DEFICIENT, in general, signifies much the same with defective. See *DEFECTIVE*.

DEFICIENT HYPERBOLA, one with only one asymptote, and two hyperbolic legs running out infinitely towards the asymptote, but contrary ways. See the article *HYPERBOLA*.

DEFICIENT INTERVAL, in music, one less by a comma than it ought to be. See *COMMA* and *INTERVAL*.

DEFICIENT NUMBERS, those whose parts or multiples, added together, fall short of the integer, whereof they are the parts; such is 8, its parts, 1, 2, 4, making only 7. See the article *NUMBER*.

DEFILE, in fortification, a straight narrow passage, through which a company of horse or foot can pass only in file, by making a small front; so that the enemy may take an opportunity to stop their march, and to charge them with so much the more advantage, in regard that those in the front and rear cannot reciprocally come to the relief of one another.

To *DEFILE*, is to reduce an army to a small front, in order to march through a defile.

DEFILING a Lodgment. See *ENFILADE*.

DEFINITE, in grammar, is applied to an article that has a precise determinate signification; such as the article *the* in English, *le* and *la* in French, &c. which fix and ascertain the noun they belong to some particular, as *the king*, *le roy*; whereas in the quality of *king*, *de roy*, the articles *of* and *de* mark nothing precise, and are therefore indefinite.

DEFINITION, the shewing the meaning of one word by several other not synonymous terms.

DEFINITION, in rhetoric, is defined by Cicero, a short comprehensive explanation of a thing.

DEFLAGRATION, in chemistry, the kindling or setting fire to a salt, mineral, &c. either alone or mixed for that purpose, with a sulphureous one, in order to purify it.

DEFLECTION of the Rays of Light, a property which Dr. Hook observed in 1675, and read an account of before the Royal Society, March 18, the same year. He says he found it different both from

reflection and refraction, and that it was made towards the surface of the opaque body, perpendicularly.

This is the same property which Sir Isaac Newton calls inflection. See the article *INFLECTION*.

DEFLUXION, in medicine, the falling of humours from a superior to an inferior part of the body. See the articles *CATARRH* and *PHthisis*.

DEFLUXION on the Eyes. See the article *EYES*.
DEFORCEMENT, in law, the casting any one out of his land, or with-holding of lands and tenements by force from the right owner.

DEFORMITY, the want of that uniformity necessary to constitute the beauty of an object.

DEFOSSION, BURYING ALIVE, a punishment which the Romans inflicted on such of their vestals as were guilty of incontinency.

DEFTERDAR, or *DEFTARDAR*, in the Turkish and Persian polity, an officer of state, answering to our lord-treasurer, who appoints deputies in every province. See *TREASURER*.

DEGLUTITION, in medicine, the act of swallowing the food, performed by means of the tongue driving the aliment into the oesophagus, which, by the contraction of the sphincter, protrudes the contents downwards.

DEGRADATION, the act of depriving a person for ever of a dignity or degree of honour, and taking away the title, badge, and privileges of it.

DEGRADATION, in painting, expresses the lessening the appearance of distant objects in a landscape, in the same manner as they would appear to an eye placed at that distance from them. See the articles *PERSPECTIVE* and *LANDSCAPE*.

DEGRADED CROSS, in heraldry, a cross divided into steps at each end, diminishing as they ascend towards the center, called by the French *perronnée*.

DEGREE, in geometry, a division of a circle, including a three hundred and sixtieth part of its circumference.

Every circle is supposed to be divided into three hundred and sixty parts, called degrees, and each degree divided into sixty other parts, called minutes; each of these minutes being again divided into sixty seconds, each second into thirds, and each third into fourths, and so on. See the articles *MINUTE*, *SECOND*, &c.

DEGREE of Longitude. See *LONGITUDE*.

DEGREE of Latitude. See the article *LATITUDE*.

A degree of the meridian on the surface of the globe is variously determined by various observers. Mr. Picart measured a degree in the latitude of 49° 21', and found it equal to 57060 French toises. But the French mathematicians, who have lately examined Mr. Picart's operations, assure us, that the degree in that latitude is 57183 toises. Our countryman, Mr. Norwood, measured the distance between London and York, and found it 905751

English

English feet, or 69 English miles, 288 yards. Mr. Maupertuis measured a degree in Lapland, in the latitude of $66^{\circ} 20'$, and found it 57438 toises. A degree was likewise measured at the equator by other French mathematicians, and found to contain 56767.8 toises. Whence it appears, that the earth is not a sphere, but an oblate spheroid. See the articles EARTH, SPHEROID, &c.

DEGREE, in the civil and canon law, denotes an interval in kinship, by which proximity and remoteness of blood are computed.

DEGREE, in chemistry, denotes the state or intensity of fire. See FIRE.

DEGREES, in music, are the little intervals whereof the concords, or harmonical intervals, are composed.

DEGREE, in universities, denotes a quality conferred on the students or members thereof, as a testimony of their proficiency in the arts or sciences, and intitling them to certain privileges.

DEHORS, in the military art, all sorts of out-works placed at some distance from the walls of a fortification, the better to secure the main places, and to protract the siege, &c. See CROWN-WORK and HORN-WORK.

DEIFICATION, in antiquity, the same with apotheosis. See APOTHEOSIS.

DEINCLINERS, or DEINCLINING DIALS, are such as both decline and incline, or recline at the same time. See the article DIAL.

DEISM, the system of religion acknowledged by the deists. See the next article.

DEISTS, in the modern sense of the word, are those persons in Christian countries, who acknowledging all the obligations and duties of natural religion, disbelieve the Christian scheme, or revealed religion. They are so called from their belief in God alone, in opposition to Christians.

DEITY, a term frequently used in a synonymous sense with God. See GOD.

DELEGATES, commissioners appointed by the king under the great seal to hear and determine appeals from the ecclesiastical court.

DELETERIOUS, an appellation given to things of a destructive or poisonous nature. See POISON.

DELF denotes a quarry of mine, where either stone or coal is dug; but is more particularly used for the veins of coal lying under ground, before it is dug up. A delf, or delve of coals, also denotes a certain quantity when dug.

DELF, in heraldry, is by some supposed to represent a square sod or turf, and to be so called from delving, or digging.

DELIA, in antiquity, feasts celebrated by the Athenians in honour of Apollo, surnamed Delius.

DELIA was also a quinquennial festival in the island of Delos, instituted by Theseus, at his return from Crete, in honour of Venus, whose statue, given him by Ariadne, he erected on that place.

DELIAC, or DELIACAL PROBLEM, a problem much celebrated in the writings of the ancients, concerning the duplication of the cube. See the articles DUPLICATION and CUBE.

DELINEATION, or DELINEATING, the same with designing. See the article DESIGNING.

DELINQUENT, a guilty person, or one who has committed some fault, or offence, for which he is punishable.

DELIQUIUM, in chemistry, signifies the solution of any body, when exposed to a cool and damp place, by the humidity it attracts from the air. The salt of tartar dissolved in the above manner is called oil of tartar per deliquium.

DELIRIUM, in physics, an incapacity in the organs of sensation to perform their functions in a proper manner, so that the mind does not reflect upon or judge of external objects as usual.

The word is derived from the Latin, *deliro*, to rave, or talk idly.

This frequently happens in fevers, from too impetuous a motion of the blood, which so far alters the secretion of the brain, as to disorder the whole nervous system.

DELIVERY, in medicine, the bringing forth a perfect fœtus or child from its mother's womb.

DELPHINUM, lark-spur, in botany, a genus of plants whose flower consists of five unequal petals, disposed circularly: of these the upper one is anteriorly more obtuse than the others, and is emarginated, and extended behind into a tubulated horn, which is straight, long, and obtuse. The two side petals are nearly of the size with the upper; and the two lower are less, and spread open. The stamina are numerous; and the fruit consists of three capsules, of an ovate-tubulated figure, joined together, which are filled with a number of angulated seeds.

There are several species of lark-spur; but the sort which is well known, and common in gardens (particularly those with double flowers of various colours) is much in esteem, and extremely beautiful.

These are annual, and may be sown in autumn or spring. Where the land is light and dry, the autumn sowing is to be preferred; for if the plants withstand the severity of winter, they blow much earlier than those sown in the spring, and their spikes of flowers are considerably larger. In order to continue their plenitude, all plants with single flowers should be destroyed so soon as they appear, reserving for seed those only which are very double.

They flower in July and August, and are great ornaments to the pleasure garden.

DELPHINUS or DOLPHIN, in astronomy, a constellation of the northern hemisphere, whose stars, according to Ptolemy and Tycho's catalogue, are 10; but in the British catalogue 18.

The story concerning the dolphin's having a place in the heavens is various: some say, that Neptune, the god of the sea, falling in love with Amphitrite,

he desired to marry her ; but she being very modest and shame-faced, hid herself from the sea god, who sent many messengers in search of the beautiful nymph, among whom was the dolphin, who was so fortunate to find her ; and by many persuasive arguments, persuaded her to return and match with Neptune, for which piece of service he was placed in heaven.

Others say, that when Bacchus had transformed the mariners that would have betrayed him into dolphins, he placed one of them in heaven, that it might be a warning for others to take heed how they carried any one out of their way, either contrary to his desire, or their own promise.

Other poets again tell us a story of one Arion, a lyric poet of Lesbos, who got great riches by his art, and as he was going to Italy, the mariners attempted to rob him ; but he desired he might be permitted to play one tune on his harp before they threw him into the sea, where a dolphin, drawn thither by the sweetness of the music, received him on his back, and carried him to Tenedos with all his money ; for which kindness, according to Ovid, he was made a constellation, who expresses himself thus :

The gods beheld the gen'rous deed, and Jove
Advanced him from the deep to shine above
Among the constellations, now divine ;
And for his share of stars, he gave him nine.

No vidius referreth this constellation to the fish that saved Jonas from being drowned.

Order.	Magn.	Name.	Bayer Let.	Right Ascension	Distance from Nor. Pole.	Var. in Right Ascen.	Var. in Declination.

DELTOIDES, in anatomy, a thick triangular muscle of the arm, being one of the three elevators. See the article ELEVATOR.

This muscle arises from the clavicle, and the acromion and spine of the scapula ; and terminates at four fingers breadth below the neck of the humerus. See the article HUMERUS.

DELUGE, an inundation or overflowing of the earth, either wholly or in part, by water.

We have several deluges recorded in history, as that of Ogyges, which overflowed almost all Attica ; and that of Deucalion, which drowned all Theffaly in Greece ; but the most terrible was that which is called the universal deluge, or Noah's flood, which overflowed and destroyed the whole earth, and out of which only Noah and those with him in the ark escaped.

DELVIN, among the miners of Cornwall, a kind of slate more usually called killas. See the article KILLAS.

DEMAIN, or DEMESNE, in its common acceptance, is used for the lands round a manor-house, occupied by the lord. See the article MANOR.

DEMAIN, or DEMESNE, in law, is commonly understood to be the lord's chief manor place, with the lands thereto belonging, which he and his ancestors have time out of mind kept in their own manual occupation, for the maintenance of themselves and their families. See the article MANOR.

DEMAIN denotes also all the parts of any manor not in the hands of freeholders.

DEMAND, in law, the calling upon a person for any thing that is due.

There are two kinds of demands, the one in deed, and the other in law. And these are again divided into three sorts ; one in writing, without speaking, as in every writ of præcipe ; one other without writing, being a verbal demand of the person who is to perform something ; and another made without either words or writing, which is termed a demand in law, as in cases of entries on lands, &c. And as an entry upon land and taking distress for rent, are a demand in law of the land and rent, so the bringing an action of debt for money due on a bond, is a demand in law of the debt.

Debt and claims are to be demanded in time by the statute of limitations, or they will be lost by law.

DEMANDANT, in law, is the plaintiff in all real actions, wherein land, &c. is demanded ; for these actions are by demands, as personal actions are by plaints.

DEMESNE, the same with domain. See DOMAIN.

DEMI, a word used in composition with other words to signify half. In words borrowed from the Latin we use femi. See the article SEMI.

DEMI-BASTION, a fortification having only one face and one flank. See the article BASTION.

DEMI-CANNON. See the article CANNON.

DEMI-CULVERIN. See also CANNON.

DEMI-

DEMI-GORGE, in fortification, half the gorge, or entrance into the bastion, not taken directly from angle to angle, where the bastion joins to the curtain; but from the angle of the flank to the center of the bastion, or the angle the two curtains would make, where they protracted to meet in the bastion. See **BASTION** and **CURTIN**.

DEMI-LUNE, a small flanked bastion, placed before the point of a bastion when it is too weak. This work is also sometimes placed before the curtain, when the moat is a little wider than it ought to be.

DEMI-QUAVER, a note in music, two of which are equal to a quaver. See the articles **SEMI-QUAVER** and **QUAVER**.

DEMI SEMI-QUAVER, in music, the shortest note, two of them being equal to a semi-quaver. See the articles **SEMI-QUAVER**, **CHARACTER**, &c.

DEMOCRACY, the same with a popular government, wherein the supreme power is lodged in the hands of the people: such were Rome and Athens of old; but as to our modern republics, Basil only excepted, their government comes nearer to aristocracy than democracy.

DEMOISELLE, in ornithology, a bird of the crane kind, something less than a heron, known also by the name of the dancing bird, on account of its frequent leaping and turning round, and varying the motion of its head at the same time. Immediately from behind each eye, springs forth a tuft of long, soft, white feathers, which tend backwards in a very graceful manner, and wave with the least air. The fore-part of the neck, on the contrary, is covered with soft, long, and slender black feathers, which fall on the breast in a very pleasing manner, sometimes close, and at other times detached like a lady's tippet.

DEMONSTRABLE, a term used in the schools, to signify that a thing may be clearly proved. Thus it is demonstrable, that the three angles of a triangle are equal to two right ones.

DEMONSTRATION, a method of reasoning, whereby the mind clearly perceives the agreement or disagreement between the ideas it considers. This knowledge, though it be certain, is not so clear and evident as intuitive knowledge. It requires pains and attention, and steady application of mind, to perceive the agreement or disagreement it considers; and there must be a progression by steps and degrees, before the mind in this way can arrive at certainty. Before demonstration, there was a doubt, which in intuitive knowledge cannot happen to the mind that has its faculty of perception left to a degree capable of distinct ideas, no more than it can be a doubt to the eye that can distinctly see white and black, whether this ink and paper be all of a colour. In every step that reason makes in a demonstrative knowledge, there is an intuitive knowledge of that agree-

ment or disagreement it seeks with the next intermediate idea, which it uses as a proof; for, if it were not so, that would yet need a proof, since, without the perception of such agreement or disagreement of the intermediate ideas, there is no knowledge produced. Each step and progression of the demonstration must also be exactly carried in the mind, and a man must be sure that no part is left out; which, because, in long deductions, the memory cannot easily retain, this knowledge becomes more imperfect than intuitive, and men often embrace fallhoods for demonstrations.

DEMONSTRATIVE, in rhetoric, one of the kinds of eloquence, viz. that which obtains in the composition of panegyrics, invectives, &c. See the article **RHETORIC**.

DEMONSTRATIVE, in grammar, a term given to such pronouns as serve to indicate or point out a thing. Of this number are, *hic, hæc, hoc*, among the Latins; and *this, that, these, those*, in English. See **PRONOUN**.

DEMULCENTS, among physicians, medicines good against acrimonious humours. Such are the roots of marsh-mallows, white lilies, of liquorice, and of viper grass, the five emollient herbs. See the article **EMOLIENT**.

DEMURRAGE, in commerce, an allowance made to the master of a ship by the merchants, for staying in a port longer than the time first appointed for his departure.

DEMURRER, in law, a stop put to any action upon some point of difficulty, which must be determined by the court, before any further proceedings can be had in the suit.

DEMURRER to Evidence, is where a question of law arises thereon; as if the plaintiff in a suit gives in evidence any records, deeds, writings, &c. upon which a law-question arises, and the defendant offers to demur upon it, then the plaintiff must join in such demurrer, or waive his evidence.

DEMURRER to Indictments, is when a criminal joins issue upon a point of law in an indictment or appeal, allowing the fact as laid to be true. And if the indictment, or appeal, prove good in the opinion of the judges by whom the demurrer is to be tried, and not by the inquest, they proceed to judgment and execution, as if the party had been convicted by confession or verdict.

DENARIUS, in Roman antiquity, the chief silver coin among the Romans, worth in our money about seven-pence three farthings. As a weight, it was the seventh part of a Roman ounce.

DENARIUS is also used in our law books for an English penny.

DENDRACHATES, in natural history, the name used by the ancients for an extremely elegant and beautiful species of agate, the ground of which is whitish, variegated with veins of a brighter white.

D E N

DENDRANATOMY, a term used by some for a description of the various parts of trees, as, root, trunk, branch, bark, wood, pith, flower, fruit, &c.

The word is formed from the Greek, *δένδρον*, a tree, *ανω*, and *τεμαίω*, to dissect.

DENITRÆ, in natural history, a name given to those species of septariæ which have representations of trees, &c.

DENEB, an Arabic term signifying tail, used by astronomers to denote several fixed stars. Thus deneb elecet, signifies the bright star in the lion's tail. Deneb adigege, that in the swan's tail, &c.

DENIER, a small French copper coin, of which twelve make a sol.

DENIZEN, in law, an alien made a subject by the king's letters patent, otherwise called donatison, because his legitimization proceeds *ex donatione regis*, from the king's gift.

DENOMINATION, a name imposed on any thing, usually expressing some predominant quality.

DENOMINATIVE QUALITY, that quality from which things take their denomination.

DENOMINATOR, in arithmetic, a term used in speaking of fractions.

The denominator of a fraction is the number below the line, shewing into how many parts the integer is supposed to be divided. Thus in the fraction $\frac{3}{4}$, the number 4 shews that the integer is divided into four parts. So in the fraction $\frac{a}{b}$, *b* is the denominator. See the article **FRACTION**.

Denominator of a ratio is the quotient arising from the division of the antecedent by the consequent. Thus 8 is the denominator of the ratio 40 : 5, because 40 divided by 5, gives 8 for a quotient. It is also called the exponent of a ratio. See the article **EXPONENT**.

DENSHRING, or **DEVENSHRING**, in husbandry. See **DEVENSHRING**.

DENSITY of Bodies, or fluids, in physics, is that property or habitude whereby they contain a certain quantity of matter under a certain bulk; accordingly, that body which contains more matter than another under the same bulk, is said to be denser than that other.

The laws of density, in general, are as follows:

1. Bodies of the same density contain equal masses under equal bulks.

2. If the bulks of two bodies are equal, their densities are as their masses. Consequently

3. The densities of equal bodies are as their gravities.

4. If two bodies have the same density their masses are as their bulks.

5. The quantities of matter contained in any two bodies are in a ratio compounded of their density and bulk.

D E N

It will therefore follow, that their gravity is in the same ratio.

6. If the masses, or gravities of two bodies are equal, their densities are reciprocally as their bulks.

7. The densities of any two bodies are in a ratio compounded of the direct ratio of their masses, and a reciprocal one of their bulks. Consequently,

8. Since the gravity of bodies is as their masses, their densities are in a ratio compounded of the direct ratio of their gravities, and a reciprocal one of their bulks.

Note, The same properties, or laws of density are to be observed with regard to fluids of all kinds whatever.

DENTALIUM, in natural history, a simple shell having no hinge, and formed only of one piece: it is of a figure approaching to cylindric or conic, and is sometimes crooked, sometimes straight; sometimes closed at one end, sometimes open at both: its animal inhabitant is called *nercis*.

DENTARIA, toothwort, in botany, a genus of plants, bearing cruciform flowers, each of which consists of four obtuse petals, with six stamina, two of which are shorter than the others. The fruit is a long, cylindrical, bilocular pod, opening with two valves, and includes a number of roundish seeds.

The root is the only part used in medicine, and is accounted drying and astringent.

DENTATED LEAF, among botanists, one notched at the edges with a number of blunt points, in some measure resembling teeth.

DENTICLES, or **DENTILS**, in architecture, an ornament in corniches, bearing some resemblance to teeth, particularly used in the Ionic and Corinthian orders. They are cut on a little square member, properly called denticulus, and the notches or ornaments themselves, dentils. In the ancient times dentils were never used in the Ionic cornice, yet they are found in the remains of the theatre of Marcellus, which some take for an argument that Vitruvius had not the direction of that building. Vitruvius prescribes the breadth of each dentil to be half its height, and the indentine or interval between each two, he directs to be two thirds of the breadth of the dentil.

DENTIFORM PROCESS, in anatomy. See the article **PYRENOIDES**.

DENTIFRICE, in medicine, a remedy for rubbing the teeth, and purging them from sordes; and for cleansing and absterging the gums, when replete with humours. There are dentifrices of various kinds and forms, some in form of a powder composed of corals, pumice-stone, salt, alum, eggshells, crabs-claws, hartshorn, &c.

The generality of operators for the teeth allow acids, such as spirit of salt, &c. to be the readiest of all dentifrices, to take off the foulness and yellowness

lowness of the teeth : but yet they do not advise a frequent use of these remedies, as they wear away too much of the teeth, and injure the gums.

DENTILS, in architecture, the same with **DENTICLES**. See the article **DENTICLES**.

DENTISCALPRA, in surgery, an instrument for scouring yellow, livid, or black teeth ; to which being applied, near the gums, it scrapes off the foul morbid crust.

DENTITION, the breeding, or cutting the children.

DENUNCIATION, a solemn publication, or promulgation of any thing.

DEOBRUENTS, in pharmacy, such medicines as open obstructions. See the article **DETERGENT**.

DEODAND, in our customs, implies a thing devoted or consecrated to God, for the pacification of his wrath, in case of any misfortune ; as a person's coming to a violent end, without the fault of any reasonable creature ; as if a horse should strike his keeper, and so kill him. In this case, the horse is to be a deodand ; that is, he is to be sold, and the price distributed to the poor, as an expiation of that dreadful event.

DEPART, in chemistry, a method of refining, or separating gold from silver, by means of aquafortis, generally called quartation.

DEPARTURE, in law, signifies a departing or going from a plea given in bar of an action. It is likewise used where a plaintiff in his declaration sets forth one thing, and after the defendant has pleaded thereto, he in his replication shews new matter different from his declaration.

DEPARTURE, in navigation, is the casting or westing of a ship, with regard to the meridian it departed or sailed from ; or it is the difference of longitude between the present meridian the ship is under, and that where the last reckoning or observation was made ; and, in all places, except under the equator, it must be accounted according to the number of miles in a degree of the parallel the ship is in.

The departure, in plane and Mercator's sailing, is always represented by the base of a right-angle triangle, where the course is the angle opposite to it, and the distance the hypotenuse. In the plane and Mercator's chart, as radius to the distance, so is the sine of the course to the departure.

But this is erroneous, except in very small distances ; for if the distance and difference of latitude be represented by the hypotenuse and perpendicular of a right-angled plain triangle, the departure will not be the base of that triangle.

DEPHLEGMATED, an appellation given to spirits well freed from phlegm.

DEPHLEGMATION, in chemistry, the same as rectification, or the freeing a spirit from its phlegm, either by distillation, or some other means.

DEPILATORY MEDICINES, those applied in order to take off the hair : such are lime and orpiment known to be, but which ought to be used with great caution.

DEPONENT, in Latin grammar, a term applied to verbs which have active significations, but passive terminations or conjugations, and want one of their participles passive.

DEPONENT, in law, a person who makes a deposition. See the article **DEPOSITION**.

DEPOPULATION, the act of committing waste.

DEPOSITION, in law, the testimony given in court by a witness, upon oath.

DEPRECATION, in rhetoric, a figure whereby the orator invokes the aid and assistance of some one ; or prays for some great evil or punishment to befall him who speaks falsely, either himself or his adversary.

DEPRECATORY, or **DEPRECATIVE**, in theology, a term applied to the manner of performing some ceremonies in the form of prayer.

DEPRESSION of Equations. See the article **EQUATIONS**.

DEPRESSION of the Pole. When a person sails or travels towards the equator, he is said to depress the pole, because as many degrees as he approaches nearer the equator, so many degrees will the pole be nearer the horizon. This phenomenon arises from the spherical figure of the earth.

DEPRESSOR, or **DEPRIMENS**, in anatomy, a name applied to several muscles, because they depress the parts they are fastened to.

DEPRESSOR LABII SUPERIORIS, or **TRIANGULARIS**, is a muscle that arises from the lower edge of the under jaw, between the masseter and quadratus, and ascends by the angle of the mouth to the upper-jaw. These two muscles acting together, express a sorrowful countenance, because they draw downwards the corners of the mouth and cheeks.

DEPRESSORES NASI, a pair of muscles arising from the os maxillare, above the dentes incisores, and are inserted into the extremities of the alæ, which they pull downwards.

DEPRESSOR ANGULI ORIS, a name given by Albinus to the muscle called by others depressor labiorum communis. See the article **DEPRESSOR LABII**.

DEPRESSORES OCULI, a pair of muscles springing from each corner of the eye, and answered by another pair of the like figure and structure, in the lower eye-lid. See the article **EYE**.

DEPRIVATION, in the canon-law, the deposing a bishop, parson, vicar, &c. from his office and preferment.

DEPTH, in geometry, the same with altitude ; though, strictly speaking, we only use the term depth to denote how much one body, or part of a body, is below another.

DEPTH of a *Battalion* or *Squadron*, in military affairs, the number of ranks, or the quantity of men, of which each file consists in a battalion or squadron.

The depth of the battalion is generally four men, and that of the squadron three.

So that if the battalion consists of six hundred men, each rank will be one hundred and fifty.

The first rank is called the front of the battalion or squadron, and the last the rear. The files which bind it on the right and left are called the flanks.

DEPURATION, in pharmacy, is the separating or freeing any fluid from all heterogeneous matter or feculencies, and thereby rendering every part of it of a similar consistence and appearance.

DEPURATORY FEVER, a name given by Sydenham to a fever which prevailed much in the years 1661, 1662, 1663, and 1664. He called it depuratory, because he observed that nature regulated all the symptoms in such a manner, as to fit the febrile matter, prepared by proper concoction, for expulsion in a certain time, either by a copious sweat, or a freer perspiration.

DEPUTATION, a mission of select persons out of a company, or body, to a prince or assembly, to treat of matters in their name. They are more or less solemn, according to the quality of those who send them, and the business they are sent upon.

DERELICTS, in the civil law, such goods as are wilfully relinquished by the owner.

DERELICT signifies also a thing forsaken, or cast away by the sea.

DERIVATION, in medicine, is when a humour, which cannot be conveniently evacuated at the part affected, is attracted from thence, and discharged at some more proper place in its vicinity; or is drawn from a noble to a more ignoble part, where it is less capable of doing injury. Thus a blister is applied upon the neck to draw thither the matter, in cases of defluxions upon the eyes.

DERIVATIVE, in grammar, a word which is derived from another, called its primitive. See **PRIMITIVE**.

Thus manhood is derived from man, deity from deus, and lawyer from law.

DERVIS, a name given to all Mahometan monks, though of various orders.

DÉSART, a large extent of country entirely barren, and producing nothing. In this sense some are sandy deserts, as those of Lop, Xama, Arabia, and several others, in Asia and Africa, those of Lybia and Zara: others are stony, as the desert of Pharan in Arabia Petrea.

The **DÉSART**, absolutely so called, is that part of Arabia south of the Holy Land, where the children of Israel wandered forty years.

DESCANT, in music, the art of composing in several parts. See **COMPOSITION**.

Descant is three-fold, viz. plain, figurative, and double.

Plain DESCANT is the ground-work and foundation of all musical compositions, consisting altogether in the orderly placing of many concords, answering to simple counterpoint. See the article **COUNTERPOINT**.

Figurative or **Florid DESCANT**, is that part of an air of music, wherein some discords are concerned, as well, though not so much, as concords. This may be termed the ornamental and rhetorical part of music, in regard that there are introduced all the varieties of points, syncopes, diversities of measures, and whatever is capable of adorning the composition.

DESCANT Double, is when the parts are so contrived, that the treble, or any high part, may be made the bass; and, on the contrary, the bass the treble. See the articles **HARMONY**, **COUNTERPOINT**, and **MELODY**.

DESCENDANT, in genealogy, a term relative to ascendant, and applied to a person who is born or issued from some other referred to: thus, mankind are said to be the descendants of Adam; and sometimes the descendants of Noah.

DESCENSION, in astronomy, is either right or oblique.

The right descension of any celestial object, is that point of the equinoctial which sets at the same time with that object in a right sphere, reckoned from the first point of Aries.

The oblique descension is the same thing in an oblique sphere.

DESCENSIONAL DIFFERENCE, is the degrees and minutes, &c. reckoned on the equinoctial, between the two points described in the preceding article.

DESCENT, in general, is the tendency of a body from a higher to a lower place.

DESCENT of heavy bodies, is that uniform accelerated motion with which they tend towards the center of the earth. See the article **ACCELERATION**.

DESCENT, or **DISCENT**, in law, an order or method whereby lands or tenements are derived to any man from his ancestors.

DESCENT, in heraldry, is used to express the coming down of any thing from above: as, a lion en descent, is a lion with his head towards the base points, and his heel towards one of the corners of the chief, as if he were leaping down from some high place.

DESCENTS, in fortification, are the holes, vaults, and hollow places made by undermining the ground.

The descent into the moat, or ditch, is a deep passage made through the esplanade and covert-way, in form of a trench, whereof the upper-part is covered with madriers and clays, to secure the besiegers.

besiegers from the enemy's fire. In wet ditches this trench is on a level with the surface of the water, but in dry ones it is sunk as deep as the bottom of the ditch.

DESCRIBENT, in geometry, a line or surface, which by moving parallel to itself, describes a surface or solid.

DESCRIPTION is such a strong and beautiful representation of a thing, as gives the reader a distinct view and satisfactory notion of it.

DESERTER, in a military sense, a soldier who, by running away from his regiment or company, abandons the service.

DESHACHE, in heraldry, is where a beast has its limbs separated from its body, so that they still remain on the escutcheon, with only a small separation from their natural places.

DESIDERATUM is used to signify a desirable perfection in any art or science: thus, it is a desideratum with the blacksmith, to render iron fusible by a gentle heat, and yet preserve it hard enough for ordinary uses; with the glass-man and looking-glass maker, to render glass malleable; with the clock-maker, to bring pendulums to be useful, where there are irregular motions; with the brazier and copper-smith, to make malleable folder; with the shipwright, to build vessels that will sail under water; with the diver, to procure manageable instruments for conveying fresh air to the bottom of the sea, sufficient for respiration, and the burning of lights; with the assay-master, to melt or copel ores or metals immediately, without the use of bellows or furnaces; and with the carvers and joiners, to fashion wood in moulds like plaster of Paris, or burnt alabaster, &c.

DESIGN, in a general sense, the plan, order, representation, or construction of a building, book, painting, &c.

In building, the term *ichnography* may be used, when by design is only meant the plan of a building, or a flat figure, drawn on paper: when some side or face of the building is raised from the ground, we may use the term *orthography*; and when both front and sides are seen, in perspective, we may call it *scenography*.

DESIGN, in the manufactories, expresses the figures wherewith the workman enriches his stuff, or silk, and which he copies after some painter, or eminent draughtsman, as in diaper, damask, and other flowered silk and tapestry, and the like.

DESIGN is also used, in painting, for the first idea of a large work, drawn roughly, and in little, with an intention to be executed and finished in large. The art of painting has been by some of the greatest masters divided into the design, or draught, the proportion, the expression, the chiaro-obscuro, the ordonnance, the colouring, and the perspective.

DESIGNING, the art of delineating or drawing the appearance of natural objects, by lines on a plane.

DESPOTICAL, in general, denotes any thing that is uncontrolled and absolute; but is particularly used for an arbitrary government, where the power of the prince is unlimited, and his will a law to his subjects: such are those of Turkey, Persia, and most of the Eastern governments; and even those of Europe, if we except the republics, England, and the Swedish government.

DESPOUILLE, in heraldry, the whole case, skin, or slough of a beast, with the head, feet, tail, and all appurtenances, so that being filled and stuffed, it looks like the entire creature.

DESPUMATION, a term sometimes used for the clarifying a liquor, by the skimming of its froth.

DESSERT, or **DESART**, a service of fruits and sweetmeats, usually served up last to table.

DESSICCATIVE, or **DESSICCATIVE**, in pharmacy, an epithet applied to such topical medicines as dry up the humours flowing to a wound or ulcer.

DESTINY, among philosophers and divines, the same with fate. See **FATE**.

DESUDATION, in medicine, a profuse and inordinate sweat, succeeded by an eruption of pustulet, called sudamina, or heat-pimples. See the articles **SUDAMINA** and **HIDRO**.

DETACHED PIECES, in fortification, are such out-works as are detached, or at a distance from the body of the place; as demilunes, ravelines, bastions, &c. In painting, the figures are said to be well detached, when they stand free and disengaged from each other.

DETACHMENT, in military affairs, a certain number of soldiers drawn out from several regiments or companies equally, to be employed as the general thinks proper, whether on an attack, at a siege, or in parties to scour the country.

A detachment of two or three thousand men, is a command for a brigadier; eight hundred for a colonel; four or five hundred for a lieutenant-colonel. A captain never marches on a detachment with less than fifty men, a lieutenant, an ensign, and two sergeants. A lieutenant is allowed thirty, and a sergeant; and a sergeant ten or twelve men. Detachments are sometimes made of entire squadrons and battalions.

DETACHMENT, in naval affairs, a certain number of ships chosen by an admiral or commodore from the rest of the fleet or squadron, and appointed to execute some particular commission.

DETENTS, in clock-work, are those stops which, by being lifted up or let down, lock or unlock the clock in striking. See the article **CLOCK-WORK**.

DETENT-WHEEL, or **HOOR-WHEEL**, in a clock,

clock, that wheel which has a hoop almost round it, wherein there is a vacancy at which the clock locks.

DETERGENTS, *Detergentia*, in pharmacy, such medicines as are not only softening and adhesive, but also, by a peculiar activity, conjoined with a suitable configuration of parts, are apt to abraze, and carry along with them such particles as they lay hold on in their passage.

DETERMINATE PROBLEM, in geometry, that which has but one, or at least a limited number of answers.

DETERMINATION, in mechanics, signifies much the same with the tendency or direction of a body in motion.

DETERMINATION, among school-divines, is an act of divine power, limiting the agency of second causes, in every instance, to what the Deity predestinated concerning them. See **PREDESTINATION**.

DESTINUE, in law, a writ or action that lies against one who has got goods or other things delivered to him to keep, and afterwards refuses to deliver them.

DETINUE of Charters. An action for detinue lies for deeds and charters which make the title to lands.

DETONATION, in chemistry, the noise and explosion which any substance makes upon the application of fire to it. It is also called fulmination.

DETRAHENS QUADRATUS, in anatomy, a muscle otherwise called platysma. See the article **PLATYSMA**.

DETRANCHE, in heraldry, a line bendwise, proceeding always from the dexter side, but not from the very angle, diagonally athwart the shield.

DEVENSHRING, or **DENSHRING**, a term used in many parts of England for burning of land. See **BURNING of Land**.

DEVIATION, in the old astronomy, a circle invented to account for the excentricity and difference in the distance of the planets when in apogee and perigee.

In the Ptolemaic system, it is called the deviation of the epicycle.

DEVIL, *diabolos*, an evil angel, one of those celestial spirits cast down from heaven, for pretending to equal himself with God.

DEVISE, or **DEVICE**, in heraldry, painting, and sculpture, an emblem used to represent a certain family, person, action, or quality; with a suitable motto, applied in a figurative sense. See **MOTTO**.

The essence of a devise consists in the metaphorical similitude between the things representing and represented.

DEVISE is frequently also used for a cipher. See the article **CIPHER**.

DEVISE, in law, the act whereby a person bequeaths his lands or tenements to another, by his last will and testament.

DEVOTION, *Devotio*, a sincere ardent worship of the Deity.

DEVOTION, among the Romans, was a kind of sacrifice, or ceremony, whereby they consecrated themselves to the service of some person.

DEVOURING, in heraldry, is when fishes are borne in an escutcheon in a feeding posture; for they swallow all the meat whole.

DEUIDER, in the manege, is applied to a horse that, upon working upon volts, makes his shoulders go too fast for the croupe to follow; so that, instead of going upon two heads as he ought, he endeavours to go only upon one.

DEUNX, in Roman antiquity, eleven ounces, or $\frac{11}{12}$ parts of the Libra. See **LIBRA**.

DEUS, GOD, among divines and philosophers. See the article **GOD**.

DEUTERO-CANONICAL, in theology, a term applied to certain books of Scripture which were added to the canon after the rest; either because they were not wrote till after the canon was compiled, or because of some debate in regard to their canonicity.

DEUTERONOMY, a canonical book of the Old Testament, and the last of the pentateuch of Moses.

This book was called Deuteronomy by the seventy Greek translators, as being a recapitulation of the laws before delivered at large.

DEUTEROSIS, the Greek name by which the Jews called their mischnah, or second law.

DEW, a light, thin, insensible rain or mist, falling on the earth while the sun is below the horizon.

Sun Dew, in botany. See the article **DROSERA**.

DEW-BERRY, in botany. See the article **RUBUS**.

DEXTANS, in Roman antiquity, ten ounces, or $\frac{10}{12}$ of their libra. See the article **LIBRA**.

DEXTER, in heraldry, an appellation given to whatever belongs to the right-side of a shield, or coat of arms: thus we say, bend-dexter, dexter-point, &c.

DEY, in matters of government, the sovereign prince of Algiers, answering to the bey of Tunis.

DIABETES, from *diabainein*, to pass off, in physics, that discharge of urine, when any liquor, soon after it is drank, is immoderately, and without undergoing almost any change, evacuated crude, and under the appearance of water.

In this disorder the patient is continually afflicted with an insatiable thirst, that cannot be removed by drinking the most liberal draughts. The liquor drank is often discharged by urine, in larger quantities than it was taken into the stomach. Thus the whole body is, by this means, consumed, and as it were dissolved; though, in some patients, the loins, the thighs, the testes, and especially the feet, become a little turgid, and a certain heat is perceived in the intestines.

A diabetes is a disease of the chronical kind, and depends upon the state of the kidneys: when recent, it sometimes admits of a cure; but when inveterate, and of long standing, it becomes incurable.

According to Lister, nothing more effectually contributes to the cure of this disorder, than all preparations of almonds, and a milk diet; and he himself gives us an instance of one cured of it by drinking as much wine, boiled with ginger, as his strength and condition would admit of; allowing him, at proper intervals, draughts of milk and water, to allay his thirst.

According to Willis, few or none at all have been observed to be cured of a diabetes by astringents; and this practitioner, as he himself informs us, often prescribed, with success, the tincture of antimony, and a solution of quick-lime in water, together with saffras, apiseeds, raisins, and liquorice.

As to the cure of the diabetes by Bristol waters, see the article *Bristol Water*.

DIACAUSTIC CURVE, is supposed to be generated in the following manner.

When the rays that issue from a radiated point are refracted by a given curve, so that the fine of the angle contained by that refracted ray, and the perpendicular to the curve, is always to the fine of the angle, contained by the incident ray, and that perpendicular in one constant ratio; the curve that touches all the refracted rays is called the diacaustic curve, or caustic by refraction. Thus, let *S* (Plate XLI. fig. 4.) be the radiating point, *SL* any incident ray, *LR* the refracted ray, *C* the center of the curvature at *L*, *CI* perpendicular from *C* on the incident ray in *I*, *CR* perpendicular on the refracted ray in *R*; join *SC* and *IR*; let *RZ* perpendicular to *RI* meet *CI* in *Z*; join *LZ* meeting *SC* in *Q*, and let *QM* parallel to *RZ* meet the refracted ray *LR* in *M*: then shall *M* be in the caustic. For, supposing the refracted ray *LR* to touch the caustic in any point *M*, and *LT* parallel to *CI* to meet *SC* in *T*, and the point *L* in describing the curve *BL* to move towards *I*; then the angular velocity of *SI* about *S* shall be to the angular velocity of *MR* about *M* in the ratio compounded of the direct ratio of the fluxion of *CI* to the fluxion of *CR* (or the ratio of *CI* or *CR*, by art. 27. of Maclaurin's fluxions, the ratio of *CI* the fine of the angle of incidence to *CR* the fine of the angle of refraction being supposed invariable) and of the inverse ratio of *SI* to *RM*. The angular velocity of *SL* about *S* is to the angular velocity of *ML* about *M* (by art. 208, and 202, of the same book.) in the direct ratio of *LI* to *LR* (or of *CZ* to *CR*, because the triangles *CZR*, *LIR* are similar) and the inverse ratio of *SL* to *LM*. Therefore *LM* is to *RM* as the rectangle contained by *CI* and *SL* is to the rectangle contained by *SI* and *CZ*, or (because *SI* is to *SL* as *CI* is to *LT*) as *LT* is to *CZ*, or *LQ* to *ZQ*; con-

sequently, *QM* and *ZR* are parallel, and the point *M* was rightly determined. When the incident rays are parallel, let *CB* parallel to those rays through the center of curvature meet *LZ* in *Q*, and *QM* parallel to *RZ* shall meet the refracted ray *LR* in the caustic at *M*. When the incident ray becomes perpendicular to the refracting curve; that is, when *L* comes to *B*, the angular velocity of *SL* is to the angular velocity of *QL* as *QB* is to *SB*; therefore the caustic meets *SC* in *Q* so that *CQ* is to *BQ* in the ratio compounded of the given ratio of *CR* (the fine of refraction) to *CI* (the fine of incidence) and of that of *SC* to *SB*: and when the incident rays are parallel, *CQ* is to *BQ* as the fine of refraction is to the fine of incidence.

Describe the circle *LICV* upon the diameter *LC*, let *CV* parallel to the incident ray *SI* meet this circle in *V*; and *RZ* shall always pass through *V*, the center of curvature *C* and incident ray *SL* being given. Therefore the point *M* is determined by applying *CR* in this circle, so that it may be to *CI* in the given ratio of the fine of refraction to the fine of incidence, joining *VR* that meets *CI* perpendicular from *C* to the incident ray in *Z*, joining *LZ* that meets *SC* in *Q*, and drawing *QM* parallel to *VR*. When *LZ* is parallel to *SC*, the refracted ray is the asymptote of the caustic.

Let *BL* (fig. 5.) be a circle, and; the incident rays being supposed parallel; let the caustic touch the refracted ray *LM* in *M*, a point of the circle; then, because *LR* is equal to *RM*, *LQ* and *CI* are bisected in *Z* and *I*: and, the triangles *CRZ*, *LRI* being similar, it follows, that *CZ*, or one half of *CI*, is to *CR* as *LI* is to *LR*. Therefore, if the invariable ratio of the fine of incidence to the fine of refraction be expressed by that of *I* to *R*, the square of *I* shall be to the square of *2R* as the square of *LI* to the square of *LR*, and *4RR—II* shall be to *II* as the difference of the squares of *LR* and *LI*, or of *CI* and *CR*, is to the square of *LI*; consequently, *3RR* is to *II—RR* as the square of the radius *CL* is to the square of *LI*, or *CV*: and in this manner Sir Isaac Newton determines the position of the ray that, after a refraction at *L*, a reflexion at *M*, and a second refraction at *G*, defines the interior rainbow; for, the rays incident about *L* being refracted so as to touch the caustic near to *M*, a point in the circle *BLM*, and being thence reflected, they will emerge nearly parallel at *G*. If it be required that the rays refracted about *L* (fig. 6.) should be reflected at *I* in the circle nearly parallel to each other; then, by art. 411. *MR* must be equal to *MI*, or one half of *LR*, *ZQ* must be one half of *LZ*, *CZ* one half of *ZI*, and therefore equal to one third part of *CI*. But *LI* is to *LR* as *CZ* is to *CR*, or as *I* is to *3R*, and *9RR—II* is to *II—RR* as the square of *CI* is to the square of *LI*; therefore *8RR* is to

II—RR as the square of the radius CL is to the square of LI, or CV; and hence the ray is determined which, after a refraction at L, two reflections at I and G, and a second refraction at H, defines the exterior rainbow; for, if G *m* be one fourth part of GH, or of LI, the rays reflected at G shall touch a caustic formed by this second refraction at *m*, and emerge parallel after their refraction at H.

DIACELTATESSON, in chemistry, a name given by Van Helmont, to a purging preparation procured from the fixed flowers of antimony.

DIACENTROS, a term used by Kepler, for the lesser diameter of a planet's orbit.

DIACHALCITIS, in surgery and pharmacy, a plaster composed of oil, axungia, and chalcitis, which formerly used to be applied after the amputation of a cancer, and on many other occasions.

DIACHYLON, in pharmacy, an emollient digestive plaster, composed of the mucilages or juices of certain herbs, litharge, and oil.

The word is formed from the Greek, δια and χυλος, juice.

DIACODIUM, in pharmacy, a syrup prepared from the heads of poppies.

The word is formed from the Greek, δια and κωδεια, a poppy-head.

DIACOPE, in grammar, the same with tmesis. See the article TMESES.

DIACOUSTICS, or DIAPHONICS, is the doctrine, or consideration of the properties of sound, refracted in passing through different mediums; that is, out of a dense into a more rare, or out of a rare into a denser, medium. See SOUND.

DIADELPHIA, the name of the seventeenth class in the Linnæan system of botany; and comprehends all such plants as bear hermaphrodite and papilionaceous flowers, and leguminous seed vessels.

The distinguishing characteristic of this class, is that the corolla is unequal, and the petals are expressed by distinct names. See the articles VEXILLUM, ALA, and CARINA.

The filaments form two dissimilar bodies: the lower one that involves the pistil; and the upper one incumbent on it: the former of these, from the middle downwards, is cylindraceous, membranaceous, and split lengthways on its upper side; but the upper half terminates in nine subulated parts, that are of the same length with, and follow the flexure of the carina of the corolla; and of which the intermediate or lower radii are longer by alternate pairs. The upper filament is single and awl-shaped; and covers the slit of the cylindraceous part of the under one. The antheræ, reckoned together, are ten in number; one on the upper filament, and nine on the under. To this may be added, that the pistil is single, growing out of the receptacle within the calyx. The germen is oblong, roundish, and lightly compressed. The style is subulate, filiform, and

ascending of the same length and position of the radii of the filament: and the stigma is downy the length of the style from the part, turned upwards, and immediately below the antheræ.

This class is the most natural; the leaves are food for cattle, and the seeds for tame quadrupeds; and comprehends peas, beans, vetches, and a number of other genera.

DIADEM, in antiquity, a head-band, or fillet, worn by kings, as a badge of their royalty. It was made of silk, thread, or wool, and tied round the temples and forehead, the ends being tied behind, and let fall on the neck. It was usually white, and quite plain, though sometimes embroidered with gold, and set with pearls and precious stones. In latter times it came to be twisted round crowns, laurels, &c. and even appears to have been worn on divers parts of the body. See CROWN.

DIADEM, in heraldry, is applied to certain circles, or rims, serving to inclose the crowns of sovereign princes, and to bear the globe and cross, or the fleur de lices for their crest. The crowns of kings are bound, some with a greater, and some with a less number of diadems. The bandage about the heads of Moors on shields is also called diadem, in blazoning.

DIADROME, in physics, the same with vibration, which see.

DIÆRESIS, in surgery, an operation serving to divide and separate the part, when the continuity is a hindrance to the cure. Some professors divide surgery into six parts, assigning to each Greek names, of which diæresis is one.

DIÆRESIS, in medicine, is the consuming of the vessels of an animal body, when from some corroding cause certain passages are made, which naturally ought to have been; or certain natural passages are dilated beyond their ordinary dimensions, so that the humours which ought to have been contained in the vessels extravasate or run out.

DIÆRESIS, in grammar, the division of one syllable into two, which is usually noted by two points over a letter, as aulāi instead of aulæ, dissolūenda for dissolūenda.

DIÆRESIS, is also the same with what is otherwise called tmesis. See TMESES.

DIAGLYPHIC, the art of cutting or engraving figures on metals, such as seals, intaglios, matrices of letters, &c. or coins for medals. See the articles ENGRAVING and SCULPTURE.

DIAGNOSTIC, from the Greek δια, with or through, and γινωσκω, to know, is that judgement of a disease that is taken from the present symptoms and condition of the patient.

DIAGONAL, in geometry, a right-line drawn across a parallelogram, or other quadrilateral figure, from the vertex of one angle to that of another.

Fig. 1.

Fig. 2.

Fig. 3.

Fig. 4.

Fig. 5.

Fig. 6.

Fig. 7.

Fig. 8.

Fig. 9.

Such are the line AD or BC (Plate XLI. fig. 7.) drawn from the angles A and B to C and D.

Some authors call it diameter, and others the diametral of the figure.

It is demonstratd, 1. that every diagonal divides a parallelogram into two equal parts: 2. two diagonals drawn in any parallelogram, bisect each other: 3. the diagonal of a square is incommensurable with one of its sides.

Add, 4. a very noble theorem in elementary geometry, first demonstratd by Mr. Lagny, in the *Memoires de l'Académie Royale des Sciences*, An. 1796, is that the sum of the squares of the two diagonals of every parallelogram, is equal to the sum of the squares of the four sides.

It is evident, at first sight, that the famed 47th proposition of Euclid, so richly worth the hecatomb it costs its author, is only a particular case of this proposition: for if the parallelogram be rektangled, it follows of course, that the two diagonals are equal; and, of consequence, that the square of a diagonal, or, which is the same thing, the square of the hypotenuse of a right angle, is equal to the squares of the two sides. If a parallelogram be oblique-angled, and of consequence, the two diagonals unequal, as is the more usual case; the proposition becomes of more extensive use.

The demonstration in oblique-angled parallelograms is thus: suppose the oblique-angled parallelogram ABCD, whereof BD is the greater diagonal, and AC the lesser: from the point A, of the obtuse angle DAB, let fall a perpendicular AE, to the side CD; and from the point B another perpendicular BF to the side DC. Then are the triangles ADE, BCF equal, and similar, as AD is equal to BC, and the angle ADE, BCF, as well as AED, BCF, are also equal; consequently DE is equal to CF. Now, by Euclid, prop. 12. lib. 2. in the obtuse-angled triangle BDC, the square of the side BD is equal to the sum of the squares of BC, and CD, and over and above, to double the rectangle of CF by CD; and by the 13th, lib. 2. in the triangle DAC, the square of the side AC is equal to the sum of the squares of AD, and CD, abating double the rectangle of the same CD, by DE, equal to CF. Consequently, the former excess precisely compensating this defect; the sum of the squares of the two diagonals is equal to the sum of the squares of the four sides. Q. E. D.

Hence, in every rhombus, or lozange, knowing one side, and a diagonal; the other diagonal will likewise be known: for as the four sides are equal; subtracting the square of the given diagonal from quadruple the square of the given side; the remainder is the square of the diagonal required.

The proposition is likewise of great use in the theory of compound motions: for in an oblique-angled parallelogram, the greater diagonal being the subtense of an obtuse; and the lesser, of an

acute angle, which is the complement of the former; the greater will be the greater, and the less the less, as the obtuse angle is the greater; so that if the obtuse angle be conceived to grow till it be infinitely great with regard to the acute one, or, which amounts to the same thing, if the two contiguous sides of the parallelogram be extended directly, end to end in a right line; the great diagonal becomes the sum of the two sides, and the lesser one, nothing. Now, two contiguous sides of a parallelogram being known, together with the angle they include, it is easy to find the subtense of that angle, i. e. one of the diagonals of the parallelogram, in numbers; which done, Mr. de Lagny's proposition gives the other. Which second diagonal thus found, is the line that would be described by a body impelled at the same time by two forces, which should have the same ratio to each other, as the contiguous sides have, and act in those two directions; which diagonal the body would describe in the same time, as it would have described either of the contiguous sides in, if only impelled by the force corresponding thereto. This is one of the great uses of the proposition: for the ratio of two forces, and the angle they make, being given, it is frequently necessary to determine, in numbers, the line a body impelled by the two forces would describe in a certain time.

DIAGRAM, in geometry, a scheme for explaining and demonstrating the properties of any figure, whether triangle, square, circle, &c. See the articles TRIANGLE, SQUARE, &c.

DIAGRAM, among ancient musicians, the same with the scale of the moderns. See the article SCALE.

DIAGRADIUM, in pharmacy, a preparation of scammony, invented by Galen; it consists in baking the scammony in a quince; but is at present seldom used.

DIAL, an instrument serving to measure time, by means of the shadow of the sun.

DIALS are differently denominated, according to their different situation, and the figure of the surface whereon they are described, for the constructing of which observe the following definitions and problems.

DEFINITIONS.

1. A dial is a plane upon which lines are described in such sort, that the shadow of the upper edge of another plane, erected perpendicular thereto, may point out the hours of the day.

2. The edge of the said plane, by which the hours of the day are marked out, is called the style of the dial, and is always parallel to the axis of the earth.

3. The Line in which the said plane intersects the plane of the dial is called the substyle.

4. The angle included between the style and substyle is called the height of the style.

The

D I A

The position of any dial is distinguished according as it is either parallel, perpendicular, or oblique; to the plane of the horizon of that place where it is fixed.

5. Those dials, whose planes are parallel to the plane of the horizon, are called horizontal dials.

6. Those dials, whose planes are perpendicular to the plane of the horizon, are called erect dials.

7. Those erect dials, whose planes are either parallel or perpendicular to the plane of the meridian, are called direct erect dials; because they front the four cardinal points.

8. All other erect dials are called declining dials.

9. Those dials, whose planes are neither parallel nor perpendicular to the plane of the horizon, are called inclining or reclining dials.

10. Those inclining or reclining dials, whose planes are either perpendicular to the meridian or prime vertical, are called direct inclining or reclining dials.

11. All those oblique dials, whose planes make an obtuse angle with the horizon, are called reclining dials; and those, whose planes make an acute angle with the horizon, are called inclining dials.

12. The arch of the horizon, which is intercepted between any given plane and that of the prime vertical, is said to be the declination of that plane.

13. The inclination of the plane is the angle which the plane makes with the horizon.

14. The reclinacion of the plane is the excess of the angle, which the plane makes with the horizon, above a right angle.

15. The intersection of the plane of the dial and that of the meridian, passing through the style, is called the meridian of the dial, or the hour-line of 12.

16. Those meridians, passing through the style, which make angles of 15° , 30° , 45° , &c. with the meridian of the place (marking the hour-line of twelve) are called hour circles; and their intersections, with the plane of the dial, hour-lines.

17. The angle, formed by the substyle and the hour line of twelve, is called the distance of the substyle from the meridian.

18. The plane's difference of longitude is the angle formed at the style by two meridians; one passing through the hour-line of twelve, and the other through the substyle.

Problem I. To describe an horizontal dial, geometrically, for any proposed latitude.

Construction. On the proposed plane draw the right line 6 A 6, (Plate XLII. fig. 1.) for the east and west line of the dial, or the hour-line of six; in the middle of which set off A a equal to the proposed thickness of your style; through A,

D I A

draw C A E, *cae* both perpendicular to 6 A 6, and let G C H be parallel thereto; make the angle C A B equal to the given latitude, and upon A B let fall the perpendicular C D; in A C produced take C F equal to C D, then make the angles C F 1, C F 2, C F 3, &c. equal to 15° , 30° , 45° , &c. respectively, and draw A 1, A 2, A 3, &c. for the hour-lines of one, two, three, &c. after noon. Moreover, take $\epsilon 11$, $\epsilon 10$, $\epsilon 9$, &c. respectively, equal to C 1, C 2, C 3, &c. and draw $a 11$, $a 10$, $a 9$, &c. for the hour-lines of eleven, ten, nine, &c. before noon.

Note, The hour-lines of four and five, whose intersections G C H fall without the plane of the dial, may be otherwise drawn in the following manner. Take A f equal to the excess of A C above C D, and make the angles 6 f 5, 6 f 4 equal to 15° , 30° respectively, also from the points 4, 5, where the lines f 4, f 5 intersect K 3, parallel to C E, draw A 4, A 5 for the hour-lines of four and five; from which, by taking 6, 7, and 6, 8, equal to 6, 5, and 6, 4, &c. and drawing A 7, A 8, &c. you will also have the hour-lines of seven and eight.

For the line 6 A 6 being the east and west line of the dial, the line C A E, perpendicular thereto, will therefore be the north and south line with regard to the center A, or in respect of that side of the style, by the shadow of which the hours after noon are pointed out; and it is evident that, as A a expresses the thickness of the style, the line *cae* will be the north and south line of the dial, with regard to the center a, answering to the morning side of the style. Moreover, since the angle C A B is equal to the latitude of the place or the elevation of the pole, by construction, it is evident, that when the style C A B is erected perpendicular to the plane of the horizon, on A a c C, the upper edge thereof will pass through the pole of the world and be parallel to the earth's axis.

Problem II. To describe an erect south dial, geometrically, for any given north latitude; or an erect north dial for any south latitude.

Construction. On the proposed plane, draw the right line 6 A 6 (fig. 2.) for the east and west line of the dial, or the hour-line of six; in the middle of which set off A a equal to the proposed thickness of your style, and from A, a draw A C, a c both perpendicular to 6 A 6, also let G C H be parallel thereto: make the angle C A B equal to the complement of the latitude, and upon A B let fall the perpendicular C D, then proceed as in Prob. I.

To shew that the upper edge of the style, when the dial is placed in its proper position, will be parallel to the earth's axis (as it ought to be by Definition II.) we may observe, in the first place, that the line 6 A 6, being the east and west line of the dial, and parallel to the plane of the horizon, the line A C perpendicular thereto (when the plane of the dial is erect, according to Definition VI.) will also

also be perpendicular to the horizon. Therefore when the plane of the style, represented by the triangle ACB , is erected perpendicular to the plane of the dial, on the line AC , it will coincide with the meridian (being perpendicular to the plane of the dial represented by the prime vertical:) and so the angle CBA being equal to the given latitude, or the elevation of the pole, (by construction) it is evident AB the upper edge of the style, when produced, will pass through the pole of the world, and so be parallel to the earth's axis.

Note, An erect north dial, for a north latitude, is constructed exactly in the same manner as an erect south dial; the only difference being in the position of the dial: in the former case the line GB being made the upper edge of the dial instead of the lower.

The same may be observed with respect to an erect south dial, for a south latitude.

Problem III. To describe an erect east dial, geometrically, for any proposed north latitude, or an erect west dial, for any south latitude.

Construction. On the proposed plane draw the right line AB , (*fig. 3.*) for the horizontal line of the dial; make the angle LBA equal to the complement of the latitude, and, perpendicular to BL , draw ACH for the hour-line of six; take Cc equal to the proposed thickness of your style, and parallel to AH draw acb ; then having assumed DC at pleasure, make the angles CDA , CDB , CDd , &c. equal to 15° , 30° , 45° , &c. respectively, and through the points a , b , d , &c. parallel to ACH , draw the lines $7a7$, $8b8$, $9d9$, &c. for the hour-lines of seven, eight, nine, &c. Moreover, take cg , ch , cl , &c. equal to Ca , Cb , Cd , &c. and through g , h , l , &c. parallel to acb , draw the lines $5g5$, $4h4$, $3l3$, &c. for the hour-lines of five, four, three, &c. The style in this case will be represented by the plane $H9a$, or $DGFE$, whose upper edge GF produced will pass through the pole of the world (as it ought by Definition II.)

For the dial being placed in its proper position, the plane thereof will coincide with the meridian (by Definition VII.) and the line BA with the horizon; whence, the angle BAC being equal to the proposed elevation of the pole by construction, the line ACH will, it is evident, point directly to the said pole, and therefore be parallel to the earth's axis. Therefore GF being parallel to AH , it must also be parallel to the earth's axis.

Note, An erect west dial for a north latitude, is constructed exactly in the same manner as an erect east dial, provided that, instead of beginning the construction from the right end B of the plane, you begin at the left end A , and that the figures expressing the hours of one, two, three, &c. in the afternoon be placed between the said left end and the hour-line of six.

The same may be observed with regard to an erect east dial for any south latitude.

Problem V. To describe a direct east reclining dial, geometrically, for any north latitude; or a direct west reclining dial for any south latitude.

Construction. On the proposed plane draw the right line IK 12, (*fig. 4.*) for the north and south line of the dial, or the hour-line of twelve, perpendicular to which draw KC : make ECK equal to the given reclination, and perpendicular to KC draw CEL ; take $KM = KE$ and make the angle AMK equal to the complement of the proposed latitude; join AC , and perpendicular thereto draw GCH , in which set off Cc equal to the proposed thickness of your style; through c draw ca perpendicular to GH , and let Aa be parallel thereto: make $CB = CE$, and joining AB , and KB , draw CD perpendicular to AB ; in AC and ac , produced, take CF and cf , each equal to CD , and from F , to the point where GH intersects IK , draw $F12$; then make the angles $12F11$, $11F10$, $10F9$, $9F8$, each equal to 15° , and the angle $cf7$ equal to the excess of 15° above the angle $CF8$: also make the angles $7f6$, $6f5$, &c. each equal to 15° , and draw the right lines $A11$, $A10$, $A9$, &c. for the hour-lines of 11, 10, 9, &c.

To shew that the upper edge of the style, when the dial is placed in its proper position, will be parallel to the earth's axis (as it ought to be by Definition II.) we may observe in the first place, that the plane of the triangle KEC , when erected perpendicular to the plane of the dial on the line KC , will be parallel to the prime vertical (by Definition X.) and perpendicular to the line IK , which, being the north and south line of the dial, is parallel to the planes of the horizon and of the meridian, and therefore, because the angle EKC expresses the reclination of the plane of the dial from the plane of the meridian, the line EK will be perpendicular to the plane of the horizon, and parallel to the plane of the meridian.

Now the triangles KEC , KBC , having the side $EC = BC$, KC common, and the angles ECK , BCK both right, will be equal and similar; therefore when the plane of the style, represented by the triangle ACB , and the plane of the triangle KBC are erected perpendicular to the plane of the dial, on the lines AC , KC respectively, the triangle AKB , as the triangles KEC , KBC then coincide, will be parallel to the plane of the meridian. Moreover, because $BK (= KE) = KM$, AK common, and the angles AKM , AKB both right, the triangles AKM , AKB will be equal and similar, and therefore $ABK = AMK =$ the complement of the given latitude by construction; consequently, the angle KAB being equal to the given latitude, the upper edge of the style AB , when produced, will pass through the pole of the world, and so be parallel to the earth's axis.

If it be required to describe a west reclining dial for a north latitude, or an east reclining one for a south latitude, the method of construction will still be the same; provided that, instead of beginning the operation towards the right end of the line IK, you begin towards the left end, and that the figures expressing the hours after noon be placed, instead of those expressing the hours before noon.

A direct west inclining dial, for a north latitude, is constructed in the same manner as a direct east reclining one, only that the points A and C change their position (A being placed, in this case, at the left end of the line LC, and C at the right end of the line IK) and that (the sun not coming on the plane till after noon) the figures expressing the hours after noon be placed instead of those before noon.

The same may be observed with regard to a direct east inclining dial for a south latitude.

Problem VI. To describe an erect south dial, geometrically, for any proposed north latitude, to have a given declination from west; or an erect north dial, for a south latitude, to decline from the east.

Construction. On the proposed plane draw the right line BC, (*fig. 5.*) for the horizontal line of the dial, and perpendicular thereto draw BA; make the angle BCA equal to the proposed latitude, and the angle CBD equal to the complement of the given declination; then, having taken BD equal to BC, draw DE perpendicular to BC: join AE, and perpendicular thereto draw *f*EG, in which set off *Ee* equal to the proposed thickness of your style; through *e* draw *ea* perpendicular to *fg*, and let *Aa* be parallel thereto: make EF equal to ED, and joining AF, draw EG perpendicular thereto; in AE and *ae* produced take EH and *eh* each equal to EG, and from H to the point where *fg* intersects AB, produced, draw H12; then make the angles 12H11, 11H10, 10H9, each equal to 15 degrees, and the angle *eh*8 equal to the excess of 15 degrees above the angle EH9: also make the angles 8*h*7, 7*h*6, 6*h*5, &c. each equal to 15 degrees, and draw the right lines A11, A10, A9, A8, A7, &c. for the hour-lines of 11, 10, 9, 8, &c.

To demonstrate that the upper edge of the style, when the dial is placed in its proper position, will be parallel to the earth's axis (as it ought to be by Definition II.) it may be observed that the line BC being parallel to the plane of the horizon, the line AB perpendicular thereto, as the dial is an erect one, will be perpendicular to the said plane; therefore the plane of the triangle BDE, when erected perpendicular to the plane of the dial, on the line BE, being perpendicular to the line AB, and parallel to the plane of the horizon, the line BD will be perpendicular to the plane of the prime vertical (because the angle DBE expresses the complement of the plane's declination from the said plane, by

Definition XII.) and consequently parallel to the plane of the meridian; therefore the plane ADB, being also perpendicular to the plane of the prime vertical, must coincide with the plane of the meridian.

Moreover, since DB is equal to BC (by Construction) the angles ABD and ABC both right ones, and AB common, it is evident, that the angle ADB is equal to the angle ACB, equal to the given latitude, and consequently that the line DA will be parallel to the earth's axis.

But the triangle AEF, when the plane of the style, represented by the triangle AFE, is erected perpendicular to that of the dial, on the substyle AE, will coincide with the triangle ADE, because DE is equal to FE, AE common, and the angles AFE, AED both right.

If it be required to describe an erect south dial for a northern latitude, to decline westerly, or an erect north dial for a southern latitude, to decline easterly; the method of construction will still be the same, only, instead of beginning the operation on the left side of AB, you must begin on the right side.

If the plane of an erect south dial, declining easterly, in a northern latitude, be inverted, the dial will then become an erect north dial, declining westerly, for the same latitude; and if the plane of an erect north dial declining westerly, in a southern latitude, be inverted, the dial will then become an erect south dial, declining easterly, for the same latitude.

In like manner, an erect south dial, declining westerly, in a northern latitude, will become an erect north dial declining easterly; and an erect north dial, declining easterly, in a southern latitude, will become an erect south dial, declining westerly.

If the declination be very great, so that the elevation of the style, above the substyle, becomes very small, the preceding method of construction will be impracticable; because the hour-lines, particularly those which fall near the substyle, unless they be continued to a great distance from the center of the dial, nearly coincide: which inconvenience may be removed by the following manner of construction.

Having drawn the style AF and the substyle AE, as is taught above, let the line EG, (*fig. 6.*) be drawn perpendicular to AF, and in AE continued, let EH be taken equal to EG; then, having drawn *f*Eg perpendicular to AE, produce AB to meet *fg* in *g*, and join Hg. Moreover, at a convenient distance, let the line CD be drawn parallel to AE, for a new substyle, and the lines LM, PQ, at as great a distance from each other as room will permit, perpendicular thereto; also from the points IN, where the lines LM, PQ intersect CD, let IK, NR be drawn perpendicular to AF.

Make

D I A

Make IS equal to IK and NO equal to NR; also make the angles ISM, NOQ each equal to the angle EHg; then, if the angles QO 11, MS 11, 11 O 10, 11 S 10, 11 O 9, 10 S 9, &c. be each made equal to 15 degrees, lines drawn through the points M, 11, 10, 9, &c. Q, 11, 10, 9, &c. respectively, will be the hour-lines of the dial.

For, if from T, the point where FA and DC continued, meet, a line be drawn through M to meet PQ in 12, the triangles TIK, TNR, and TIM, TN 12, will be respectively similar; and therefore $IM : N 12 :: IK : NR :: IS : NO$: But $IM : NQ :: IS : NO$, by construction, therefore $N 12 = NQ$, consequently the line QM, continued, will pass through T. In like manner it may be proved that the other hour-lines will pass through T, the center of the dial; the style being here represented by the trapezium IewN.

Problem VII. To describe an east declining dial, geometrically, for any proposed northern latitude, to have a given reclination from the south; or a west declining dial, for a southern latitude, to have a given reclination from the north.

Construction. Having drawn the style AF and the substyle AE (fig. 7.) answering to the given declination, according to problem vi. complete the parallelogram ABEK, and in BE produced take $EH = EF = ED$; also join K, H and make the angle EKL equal to the given reclination. On KL, produced, let fall the perpendicular HM and taking EO equal to EL, draw OI, parallel to EB, intersecting BD in Q.

On the proposed plane (fig. 8.) draw SXT for the horizontal line, in which set off $ST = BE$ and $TX = OQ$; also, perpendicular to ST, draw SR and TW equal to KL and LM respectively: draw RW for your substyle, perpendicular to which draw fWg and in it set off WY ($= HM$) for the altitude of your stile, and Ww for its thickness; also draw wr perpendicular and Rr parallel to fg . In RW and rw produced take Wa and wb each equal to WZ, perpendicular to RY, and through X draw RX 12 meeting fg in 12; join a , 12 then make the angles 12 a 11, 11 a 10 each equal to 15 degrees, and the angle $wb 9$ equal to the excess of 15 degrees above the angle $Wa 10$. Also make the angles $9b 8$, $8b 7$, &c. each equal to 15 degrees, then right-lines drawn from R to 11, 10, 1, 2, and from r to 9, 8, 7, 6 will be the hour-lines of 11, 10, 1, 2, 9, &c.

In order to shew that the upper edge of the style, when the dial is placed in its proper position, will be parallel to the earth's axis (as it ought to be by definition 2) it has been already proved, in the preceding problem, that when the plane ABEK (fig. 1.) is perpendicular to the plane of the horizon, the style FA is parallel to the earth's axis, in which case (the planes KEH, AEF and EBD being

D I A

all perpendicular to the plane ABEK) the lines ED, EH and EF coincide, and consequently express the altitude of the point F, of the style, above the plane ABEK. Now, as the angle EKL expresses the given reclination or the inclination of the proposed plane to the vertical plane, if the lines AH, AM be drawn, HM will express the altitude of the point F above the plane AKM and AH will coincide with AF and so be parallel to the earth's axis. But as SR (fig. 2.) is by construction equal to KL, if the parallelogram SV be completed, VW will be $= KM$ the triangle RVW equal and similar to the triangle AKM, and the triangle R W Y equal and similar to the triangle AMH; consequently when the plane of the style, represented by the triangle R W Y, is erected perpendicular to the plane of the dial on the line RW, the upper edge (RY) thereof will pass through the pole of the world, and so be parallel to the earth's axis.

If the dial be constructed for a northern latitude and EL be greater than EH, or, which is the same thing, KL greater than KM, the north pole will be elevated and the point W, in the substyle RW, will fall on the contrary side of R.

If it be required to describe a reclining south dial, for a northern latitude, to decline westerly; or a reclining north dial, for a southern latitude, to decline easterly; the method of construction will still be the same, only, instead of beginning the operation on the left side of AB and RS, you must begin on the right side of them.

In describing a reclining north dial, for a north latitude, to decline easterly; or a reclining south dial, for a southern latitude to decline westerly; the construction differs from the former, inasmuch that the points A, B, E and K change the position and fall in the places of E, K, A and B respectively, and that the line KL falls on the contrary side of KE, with respect to the line KH; also that the points R, S, T and V fall in the places of T, V, R and S respectively, and that the hour-lines of 1, 2 become those of 11, 10, and those of 11, 10, 9, &c. become the hour-lines of 1, 2, 3, &c.

If the plane of a reclining south dial, declining easterly; in a northern latitude, be inverted; the dial will then become an inclining north dial, declining westerly, for the same latitude; but the morning hour-lines in the reclining dial will become the afternoon hour-lines in the inclining one. In like manner, a reclining north dial, declining westerly, in a southern latitude, will become an inclining south dial, declining easterly, for the same latitude. Also a reclining south dial, declining westerly, in a northern latitude, will become an inclining north dial, declining easterly, for the same latitude; and a reclining north dial, declining easterly, in a southern latitude, will become an inclining south dial, declining westerly, for the same latitude.

latitude. Moreover, a reclining north dial, declining easterly, in a northern latitude, will become an inclining south dial, declining westerly, for the same latitude; and a reclining south dial, declining westerly, in a southern latitude, will become an inclining north dial, declining easterly, for the same latitude.

Having now given the construction of the various kinds of dials, whether erect, declining, reclining, or inclining, we shall here put down the general demonstration of the method, all along used, in drawing of the hour-lines, which we promised in our first problem, and thought would be better than taking up room with the particular demonstration of each problem, as they all depend upon the same principle.

Let AE (fig. 9.) be the substyle, AF the style, $A 12$ the meridian line, and AG any other hour-line at pleasure; making (as is every where done) EH perpendicular to AF and $Eb = EH$; also let bG and GH be drawn.

Because the sun, in his apparent diurnal revolution, describes an angle of 15° each hour about the axis of the earth, or the style AF of the dial, which is parallel to it, it is evident that if a plane, coinciding with (or lying upon) the line AF , be supposed to revolve about the same as an axis, at the rate of 15° per hour, it will when produced pass through the sun, and consequently its intersection with the plane of the dial will mark out the true position of the hour-lines.

Now it is known that the angle included between any two planes is equal to (or measured by) the angle made by two lines in those planes perpendicular to their common intersection: also, by the general method all along used, the angle EbG is equal to the given hour-angle betwixt the time of the planes falling upon the substyle and the proposed hour-line AG : but the line HG is perpendicular to the axis AF , because the plane GHE , being perpendicular to the plane of the style EFA , all the lines in that plane (and consequently HG) will be perpendicular to AF . Moreover, the triangles EHG , EbG having $EH = Eb$, EG common, and the angles HEG and bEG both right, are equal in all respects, and consequently the angle GHE , measuring the inclination of the plane betwixt the times of its falling on the substyle and the hour-line AG , will be equal to the angle $Gbe =$ the said hour angle by construction.

The above curious track was written by the late celebrated Mr. T. Simpson, of Woolwich, and published sometime ago in a periodical work called *Mathematical Exercises*; but as that book is in very few hands, and not now to be had, we dare say it will here be an acceptable present to the public, and we need not be ashamed to acknowledge that it was not in our power to have said any thing better on the subject.

DIALECT, *διαλεκη*, an appellation given to the language of a province, in so far as it differs from that of the whole kingdom. The term, however, is more particularly used in speaking of the ancient Greek, whereof there were four dialects, the Attic, Ionic, Æolic, and Doric, each of which was a perfect language in its kind, that took place in certain countries, and had peculiar beauties.

In Great-Britain, besides the grand diversity of English and Scotch, almost every county has a dialect of its own, and differing considerably in pronunciation, accent, and tone, although one and the same language.

DIALECTICS, *Dialectica*, in the literary history of the ancients, that branch of logics which taught the rules and modes of reasoning. See **LOGIC**.

DIALING, the art of constructing all manner of dials.

The antiquity of dials is beyond all doubt very great: some attribute their invention to Anaximenes Milefius, and others to Thales: Vitruvius mentions one made by the ancient Chaldean Berosus, on a reclining plane, almost parallel to the equinoctial. Aristarchus Samius invented the hemispherical dial: and there were at the same time some spherical ones with a needle for the gnomon. The discus of Aristarchus was an horizontal dial, with its limb raised up all round, to prevent the shadow from stretching out too far.

It was very late before the Romans knew any thing of dialing: Pappyrus Curfon set up the first sun-dial at Rome, about the year of the city 460; before which time, says Pliny, they had no account of time, but the sun's rising and setting. This dial must have been but a very indifferent one; for so ignorant were they of the principles of dialing in the consulship of M. Valerius Messalla, which was some time after this that he set up a dial at Rome, which he brought from a port of Sicily, whose latitude was several degrees different from that of Rome.

Dials seem to have been in use much sooner amongst the eastern nations, especially the Jews; for we read of the dial of Ahaz, who, according to the best chronologists, began to reign within twelve years after the building of Rome.

The first professed writer on dialing that we know of is Clavius, who demonstrates both the theoretical and practical parts of it after the rigid method of the ancients. After him Dechaies, Ozanam, Picard, Walkerius, and De la Hire have handled this subject, and made great improvements in it. Their works, together with some considerable additions, have been republished by Sturmius, Coetfias, and Bion, and have been translated into our own language by several hands.

But dialing seems to have received its greatest improvements from our own countrymen, Gunter, Wright, Foster, Collins, Molyneux, and others.

DIALING-GLOBE, an instrument of brass or wood, with a plane fitted to the horizon, and an index, so contrived as to give a clear illustration of the principles on which dials are made.

DIALING-LINES, or SCALES, are graduated lines placed on rulers, or the edges of quadrants and other instruments, to expedite the construction of dials. These are, 1. A scale of six hours, which is only a double tangent, or two lines of tangents, each of 45°, set together in the middle, and equal to the whole line of lines, with the declination set against the meridian altitudes in the altitude of the place. 2. A line of latitudes, which is fitted to the hour-scale, and is made by this canon. As the radius : to the chord of 90° :: so are the tangents of each respective degree of the line of latitudes : to the tangents of other arches ; and then the natural sines of these arches are the numbers which, taken from a diagonal scale of equal parts, shall graduate the divisions of the line of latitudes to any radius. The lines of hours and latitudes are, in general, for pricking down all dials with centers.

The other scales are particular, and give the several requisites for all upright declining dials by inspection. They are, 1. A line of chords. 2. A line for the sub-style's distance from the meridian. 3. A line for the style's height. 4. A line of the angle of 12 and 6. 5. A line of inclination of meridians.

DIALING-SPHERE, an instrument made of brass, with several semi-circles sliding over each other upon a moveable horizon ; serving to demonstrate the nature of spherical triangles, as well as to give the true idea of drawing dials on all sorts of planes.

DIALING, among miners, the same with plumbing. See the article **PLUMBING**.

DIALOGISM, *διαλογισμος*, in rhetoric, is used for the soliloquy of persons deliberating with themselves, as the following of Juno, in the first Æneid of Virgil :

— *mene incepto desistere viam ?*
Nec posse Italia Teucrorum avertere regem ?
Quippe vector satis ? &c.

In this sense it is distinguished from dialogue.

DIALOGUE, in matters of literature, a conversation between two or more persons, either by writing or by word of mouth.

The word is formed from the Greek, *δια*, together, and *λογος*, a discourse.

DIALYSIS, in grammar, a mark or character, consisting of two points, · ·, placed over two vowels of a word, in order to separate them, because otherwise they would make a diphthong, as Mosaic, &c. See the article **DIERESIS**.

DIAMETER of a Circle, in geometry, is a right-line passing through the center, and termi-

nating both ways in the circumference. See the article **CIRCLE**.

DIAMETER of a Curve, in the higher geometry, is a line, either right, or curved, which bisects all parallels drawn from one point of the curve to another.

DIAMETER of a Sphere, is the diameter of the semi-circle, by whose rotation the sphere is generated ; in which sense it is the same with axis. See the article **AXIS**.

DIAMETERS of the heavenly Bodies, in astronomy, are different, according to different authors ; owing either to the different degrees of perfection in the instrument made use of, or else to the different degrees of accuracy in the observers, or perhaps to both : we shall give the quantities of such of them as have come to our knowledge.

Object.	Observer.	Greatest diameter	Least diameter
Sun	Ptolemy — —	33.20.0	31.20.0
	Tycho — —	32. 0.0	30. 0.0
	Kepler — —	31. 4.0	30. 0.0
	Cassini — —	32.10.0	31. 8.0
	De la Hire — —	32.43.0	31.38.0
	Hally — —	32.43.0	31.38.0
	De la Caille — —	32.39.2	31.34.4
	Mayer — —	32.38.6	31.33.8
Moon	Ptolemy — —	35.20.0	31.20.0
	Tycho — —	28.48.0	25.36.0
	Kepler — —	36. 0.0	32. 0.0
	De la Hire — —	32.44.0	30. 0.0
	Hally — —	33.30.0	26.30.0
	Mayer — —	33.36.0	29.25.0
	Bradley — —	33.36.5	28.54.2
		33.40.0	29. 0.5
Saturn	Tycho — —	2.12.0	1.34.0
	Hevelius — —	0.19.0	0.14.0
	Huygens — —	0. 0.0	0. 0.0
Jupiter	Tycho — —	3.59.0	2.14.0
	Hevelius — —	0.24.0	0.14.0
	Huygens — —	0. 0.0	1. 4.0
Mars	Tycho — —	6.46.0	0.57.0
	Hevelius — —	0.20.0	0. 2.0
	Huygens — —	0. 0.0	0.30.0
Venus	Tycho — —	4.40.0	1.52.0
	Hevelius — —	1. 5.0	0. 9.0
	Huygens — —	0. 0.0	1.25.0
Mercury	Tycho — —	3.57.0	1.29.0
	Hevelius — —	0.11.0	0. 4.0

It must be noted, that Tycho made all his observations with the naked eye, which makes his differ so much from the others.

DIAMETER of a Column, in architecture, is its thickness just above the base. See **COLUMN**.

From this the module is taken, which measures all the other parts of a column. See the article **MODULE**.

DIAMOND, *Adamas*, in natural history, a stone which, though naturally colourless like the purest water, is eminently distinguished from all others of the colourless kind by the lustre of its reflections.

It is found sometimes in an angular, and sometimes in a pebble-like form. In its angular state however it does not, like the rest, resemble the common spring crystal, but the more perfect bodies of that class, the double-pointed ones.

The true figure of the diamond in its angular, that is, its more perfect form, is an inequilateral octahedron, composed of two quadrilateral pyramids affixed base to base, and consequently their points turned the opposite way; these the jewellers call six-pointed stones: but besides this, there are two other less perfect angular figures, a columnar one of six sides, and an oblong quadrilateral column with two truncated ends; besides, there is an almost infinite variety of others, cornered and pointed, but which properly belong to it in its pebble-form. In this state it is sometimes roundish, sometimes oblong, and sometimes flat, and in some specimens perfectly smooth, in others full of inequalities on the surface.

In whichever of these forms the diamond is found, it is the same stone, and when polished has the same qualities in proportion to its perfection and purity.

The diamond, like all other transparent fossils, is liable to be tinged by metalline particles, and is sometimes found with a cast of red, sometimes blue, sometimes green, and more frequently yellow. The small diamonds are vastly the more plentiful, the others are found more and more rarely as they increase in size. The largest ever certainly known is now in the possession of the Great Mogul; its weight is 279 carats, and its value is computed at between seven and eight hundred thousand pounds.

As diamonds have originally, without all question, being concentered out of a fluid, it is not at all surprising, that among the various accidents such a concretion must have been attended within the bowels of the earth; some parts of the matter should have shot into quadrangular pyramids, while other parts of it form themselves into hexangular, pyramidal, or pebble-like concretions.

The diamond in its native state is sometimes bright as if polished by art, but more frequently its surface is observed with foulness of various kinds; and sometimes it is, as the diamond-cutters call it,

veiny, that is, it has certain points inconceivably hard on its surface.

The diamond bears the force of the strongest it is unhurt, if ever so long continued in it, provided be not removed too suddenly into the cool air, when it will sometimes crack. Exposed to the solar rays collected in the focus of a large lens, it after some time splits into several very thin flakes, like those of tale, and these soon after run into a kind of glass, which has nothing of the hardness or lustre of the diamond.

The places whence we have the diamonds are the East-Indies, in the island of Borneo, and in the kingdom of Visapour, Golconda, Bengal; and the Braills in the West-Indies.

The diamond, as has been observed, is the hardest of all precious stones; it can only be cut and ground by itself, and its own substance.

To bring it to that perfection which augments its price so considerably, they begin by rubbing two stones against each other, while rough, after having well cemented them to the ends of two sticks, or blocks, called cutting sticks, thick enough to be held in the hand. It is this powder thus rubbed off the stone, and received in a little box for that purpose, called the cutting-box, which serves to grind and polish the stones.

Diamonds are cut and polished by means of a mill, which turns a wheel of cast iron, sprinkled over with diamond dust, mixed with oil of olives.

The same dust, well ground and diluted with water and vinegar, is used in the sawing of diamonds, which is performed with an iron or brass wire as fine as a hair.

Sometimes, instead of sawing the diamonds, they cleave them, especially if there be any small shivers in them; but the Europeans rarely run the risque of cleaving, for fear of breaking them.

A rough diamond ought to be chosen uniform, of a good shape, transparent, not quite white, and free from flaws and shivers.

Shivers are caused in diamonds by this, that the miners, to get them more easily out of the vein, which winds between two rocks, break the rocks with huge iron levers, which shakes and fills the stone with shivers.

The ancients had two mistaken notions as to the diamond; the first is, that it becomes soft, by sleeping it in hot goat's blood; and the second, that it is malleable, and bears the hammer; but however, experience has shewn the contrary, there being nothing capable of mollifying the hardness of the stone; and its hardness is such, that it will endure being struck at pleasure with the hammer.

The finest diamonds now in the world are that of the Great Mogul, weighing 279 carats, as has been already observed; that of the great duke of Tuscany, weighing 139 carats; and that known in France by the name of grand fancy, which is one of the crown jewels,

jewels, weighing 106 carrats; whence comes its name fancy, which is a corruption of cent. six; that is, 106.

Valuation of DIAMONDS, among jewellers, is thus calculated: they suppose the value of a rough diamond to be 2*l*. per carat; then to find the value of those of greater weight, they multiply the square of their weight by 2, and this last product is the value of the diamonds in their rough state: thus, the value of a rough diamond, weighing 4 carats, is equal $4 \times 4 \times 2 = 16 \times 2 = 32$ *l*. and so in other cases.

Again, to find the value of wrought diamonds, they suppose half their weight lost in the manufacturing them; and therefore multiply the square of double their weight by 2: thus the value of a wrought diamond, weighing 3 carats, is equal $6 \times 6 \times 2 = 36 \times 2 = 72$ *l*.

Cornish DIAMOND, in natural history, a name given to a kind of crystals, from their being found in Cornwall.

Rough DIAMOND, is the stone as nature produces it in the mines.

Rose DIAMOND, is that quite flat underneath, with its upper-part cut in divers little faces, usually triangles, the uppermost of which terminate in a point.

Table DIAMOND, is that which has a large square face at top, encompassed with four lesser.

Brilliant DIAMOND, is that cut in faces, both at top and bottom; and whose table, or principal face at top, is flat.

DIAMOND, in the glass trade, an instrument used for squaring the large plates or pieces; and among glaziers, for cutting their glass.

These sort of diamonds are differently fitted up; those used for cutting looking-glass, &c. are called plough-diamonds, fitted into a kind of plane; and those made use of by glaziers, are set in an iron ferril, about two inches long, and a quarter of an inch or somewhat more, in diameter; and in which is a handle of box, ebony, &c. fitted to the ferril, for holding it by.

DIAMOND, in Heraldry, a term used for expressing the black colour in the achievements of peerage.

Guillim does not approve of blazoning the coats of peers by precious stones instead of metals and colours; but the English practice allows it. Morgan says the diamond is the emblem of fortitude.

DIAMORUM, in pharmacy, a preparation of mulberries and honey, used against diseases of the throat, and for stopping dysenteries, &c.

DIANÆ ARBOR, or *ARBOR LUNÆ*, in chemistry, the beautiful crystallizations of silver, dissolved in aquafortis, to which some quicksilver is added; and so called from their resembling the trunk, branches, leaves, &c. of a tree.

DIANDRIA, the name of the second class in the Linæan system of botany, and comprehends all such plants as bear hermaphrodite flowers, furnished with two stamina in each; of this class are the jasmine, phillyrea, lilac, olive, sage, rosemary, with several other genera.

DIANTHERA, in botany, a genus of plants whose corolla consists of a single ringent petal with two filaments topped with twin antheræ; the fruit is a bivalvular capsule, with two cells, each containing a solitary lentiform seed.

DIANTHUS, in botany, a name given by Linæus to the caryophyllus of other botanists, and comprehends the pink, carnation, clove july-flower, and sweet-william. See the articles *PINK*, *CARNATION*, &c.

DIAPASMA, in pharmacy, a name for all powders sprinkled on the body, whether as perfumes or otherwise. See the article *CATAPASMA*.

DIAPASON, in music, a musical interval, by which most authors, who have wrote upon the theory of music, use to express the octave of the Greeks. See *OCTAVE*.

DIAPASON, among the musical instrument-makers, a kind of rule or scale, whereby they adjust the pipes of their organs, and cut the holes in their flutes, hautboys, &c. in due proportion, for performing the tones, semi-tones, and concords just.

A square being divided into eight parallelograms, the points wherein a diagonal line intersects all these parallelograms, express all the usual intervals in music: and on this principle it is that the diapason is founded. There is a particular kind of diapason for trumpets, serving as a standard of the different magnitudes they must have to perform the four parts of music. See the article *TRUMPET*.

There is another for sackbuts, shewing how far they are to be lengthened and shortened, to raise or fall from one tone to another.

The bell-founders have likewise a diapason, serving to regulate the size, thickness, weight, &c. of their bells.

DIAPASON DIAEX, in music, a kind of compound concord, whereof there are two sorts; the greater, which is in the proportion of 10:3; and the lesser, in that of 16:5.

DIAPASON DIAPENTE, in music, a compound consonance in a triple ratio, as 3:9. This interval, says Martianus Capella, consists of nine tones and a semi-tone, nineteen semi-tones, and thirty-eight dieses. It is a symphony made when the voice proceeds from the first to the twelfth sound.

DIAPASON DIATESSARON, in music, a compound concord, founded on the proportion of 8:3. To this interval Martianus Capella allows eight tones and a semi-tone, seventeen semi-tones, and thirty-four dieses.

This is when the voice proceeds from its first to its eleventh found. The moderns would rather call it the eleventh.

DIAPASON DITONE, in music, a compound concord, whose terms are as 10:4, or 5:2.

DIAPASON SEMIDITONE, in music, a compound concord, whose terms are in the proportion of 12:5.

DIAPYCNESIS, in medicine, a transudation of the fluids through the sides of the vessels that contain them, occasioned by the blood's becoming too much attenuated, or the pores becoming too patent.

DIAPENSIA, in botany, a genus of plants, whose flower consists of a monopetalous hypocrateriform corolla, with five filamina. The fruit is a trilocular roundish capsule, inclosing a great number of roundish seeds.

DIAPENTE, in the ancient music, an interval marking the second of the concords; and with the diatessaron, an octave.

This is what, in the modern music, is called a fifth.

DIAPENTE COL DITANO, in music, is, by Zarlino, and many others, used for what we call the seventh major. See the article SEVENTH.

DIAPENTE COL SEMIDITANO, in music, is the seventh minor. See the articles MINOR and MAJOR.

DIAPENTE, in pharmacy, is used for a medicine compounded of five several drugs or ingredients.

DIAPERED, or DIAPRE, in heraldry, the dividing of a field in planes, like fret-work, and filling the same with variety of figures. This chiefly obtains on bordures, which are diapered or fretted over, and the frets charged with things proper for bordures. Baron renders it *variatus*, which is not sufficient to express the several things of which it is variated.

DIAPHANOUS, an appellation given to all transparent bodies, or such as transmit the rays of light; a quality which, according to the Cartesians, is owing to the rectitude or straightness of their pores; but, according to Sir Isaac Newton, to the homogeneity of the substance of these bodies, and of the medium which occupies their pores.

DIAPHOENICUM, in pharmacy, a sort of medicine or electuary, chiefly made of dates. It purges serosities, and excites the menses. It is also used in dropfies, lethargies, apoplexies, and palsies.

DIAPHORESIS, *διαφορησις*, in medicine, an elimination of the humours in any part of the body through the pores of the skin. See the article PERSPIRATION.

DIAPHORETICS, among physicians, all medicines which promote perspiration. See the article ALEXIPHARMIC.

DIAPHRAGM, in anatomy, the part which separates the thorax from the abdomen; vulgarly called the midriff.

The word is derived from the Greek, *διαφρασσα*, to inclose or wall in.

It is also called *septum transversum*, or cross-wall, from its situation, because it divides the trunk of the body into two cavities, the thorax and abdomen. It is composed of two muscles; the first and superior of these arises from the sternum, and the ends of the last ribs, in each side. Its fibres, from this semi-circular origination, tend towards their center, and terminate in a tendon, or aponeurosis, which hath always been taken for the nervous part of the midriff. The second and inferior muscle comes from the vertebrae of the loins by two productions, of which that on the right-side comes from the first, second, and third vertebrae of the loins; that on the left-side is somewhat shorter; and both these productions join and make the lower part of the midriff, which joins its tendon with the tendon of the other, so as that they make but one membrane, or rather partition. It is covered with a membrane on its upper-side, and by the peritonæum on the lower-side. It is pierced in the middle for the passage of the vena cava, in its lower-part for the oesophagus, and the nerves which go to the upper orifice of the stomach; and betwixt the productions of the inferior muscle, passes the aorta, the thoracic duct, and the vena azygos. It receives arteries and veins called phrenicæ, from the cava and aorta; and sometimes on its lower-part two branches from the vena adiposa, and two arteries from the lumbares. It has two nerves which come from the third vertebrae of the neck, which pass through the cavity of the thorax, and are dispersed in the muscles of the midriff. In its natural situation, it is convex on the upper-side towards the breast, and concave on its lower side towards the belly: therefore, when its fibres swell and contract, it must become plane on each side, and consequently the cavity of the breast is enlarged to give liberty to the lungs to receive the air in inspiration; and the stomach and intestines are pressed for the distribution of the chyle: but it diminishes the cavity of the breast when it resumes its natural situation, and presses the lungs for the expulsion of the air in expiration.

DIAPHORESIS, in rhetoric, a figure of oratory, expressing the uncertainty of the speaker how he shall proceed in his discourse.

DIARBEQ, or DIARBECK, a province in Asia, answering to the ancient Mesopotamia: it is situated on the river Tigris, near its source, in the 42^d deg. east long. and in the 37th deg. 30 min. north lat. It is also the capital of the same province.

DIARRHODON, in pharmacy, a name given to divers compositions in which roses are the principal ingredient.

DIAR-

Dominic, a native of Spain, was approved of by Innocent III. in 1215, and confirmed by a bull of Honorius III. in 1216.

DOMINION, *Dominium*, in the civil law, signifies the power to use or dispose of a thing as we please.

DOMINUS, in the civil law, he who possesses any thing by right of purchase, gift, loan, legacy, inheritance, payment, contract, or sentence.

DOMINUS, in the feudal law, he who grants a part of his estate in fee to be enjoyed by another.

DONATION, an act whereby a person transfers to another, either the property or the use of something, as a free gift. In order to be valid, it supposes a capacity both in the donor and donee; and requires consent, acceptance, and delivery; and by the French law, also registry. Civilians distinguish donation into pure and conditional. *Donatio pura* is when one gives a thing with an intention that it become immediately the property of the donee, never to revert to the donor; and this from no other motive than his generosity. *Donatio conditionalis* is when one gives a thing with an intention that it become the property of the donee, upon performing some condition stipulated.

DONATISTS, Christian schismatics in Africa, who took their name from their leader Donatus.

DONATIVE, a gratuity, or present, made to any person.

DOOR, in architecture, an aperture in a wall to give entrance and exit into and out of a building, or any apartment thereof.

It is laid down as a rule, that the doors of an house be as few in number, and as moderate in dimensions, as possible; as all openings are weakenings.

Secondly, That they do not approach too near the angles of the walls, it being a very great solecism to weaken that part which strengthens all the rest.

Thirdly, That the doors, if possible, be placed over one another, that void may be over void, and full over full, which circumstance will greatly strengthen the whole fabric.

Fourthly, That if possible they may be opposite to each other, in such a manner, that one may see from one end of the house to the other, which will not only be very graceful, but most convenient, in respect that it affords means of cooling the house in summer, by letting the air through it, and by keeping out the wind in winter, which way soever it fit.

Fifthly, It is not only ornamental, but very secure, to turn arches over doors, which will discharge them in a great measure from the superincumbent weight.

The proportions of doors are adjusted by those of a man. In large buildings, they must be always larger than in smaller; but should not be less than six feet high in any to admit a man of a just stature

erect: and as the breadth of a man, with his arms placed akembo, is nearly subduple his height, the width ought never to be less than three feet. Some architects give us these dimensions following; in small buildings, the breadth of the door four feet, or four and a half; in the middling buildings five, or six; in large ones seven, or eight: in chambers of the first story three and a half, three and three fourths, or four; of the second, four, or four and a half; of the third, five, or six; in churches seven or eight; in gates, nine, ten, or twelve: hence their height is easily determined, except for the gates of cities, which should only be four-fifths of their breadth.

DORADO, in ichthyology, the same with guaracema. See **GUARACAPEMA**.

DOREE, or **JOHN DOREE**, a fish, called by authors faber. See the article **FABER**.

DORIC, in general, any thing belonging to the Dorians, an ancient people of Greece, inhabiting near Mount Parnassus.

DORIC ORDER, in architecture, the second of the five orders, being that between the Tuscan and Ionic.

This order seems the most natural and best proportioned of all the orders, the several parts of it being founded on the natural position of solid bodies. Accordingly, the Doric is the first, and most ancient of the orders of architecture, and is that which gave the first idea or notion of regular building.

It was indeed more simple at its first invention, than it is at present; and when they came in after times to adorn and enrich it more, the appellation of Doric was restrained to this richer manner, and then they called the primitive, simple manner by the new name of Tuscan.

Some time after its invention it was reduced to the proportions, strength, and beauty of the body of a man: hence, as the foot of a man was judged the sixth part of his height, they made the Doric column six diameters high. After that, they added another diameter to it, and made it seven, which augmentation seemed to bring it nearer to the proportion of a man, the human foot, at least in our days, not being a sixth, but nearly a seventh part of the body.

The characters of the Doric order, as they are now managed, are, the height of its column, which is eight diameters; the frieze, which is adorned with triglyphs, drops, and metopes; its capital, which is without volutes, and its admitting of cymatiums.

It has been already observed, that the ancients had two Dorics; the first of which was the more simple and massive, and was chiefly used in temples; the second, which was the more light and delicate, they used in porticos and theatres.

The Doric is used by the moderns, on account of its solidity, in large, strong buildings, as in the gates

gates of cities and citadels, the outsidcs of churches, and other massy works, in which delicacy of ornaments would not be suitable.

The most considerable ancient monument of this order is the theatre of Marcellus at Rome, the capital, the height of the frieze, and projecture of which are much smaller than in the modern architecture.

Vignola adjusts the proportion of the Doric order as follows: he divides the whole height of the order without the pedestal into twenty parts, or modules, one of which he allows to the base; fourteen to the shaft, or fust; one to the capital; and four to the entablature: the several parts and members may be seen under their respective articles, COLUMN, CORNICHE, BASE, FRIEZE, &c.

DORIC DIALECT, in grammar, one of the five dialects, or manners of speaking, which were principally in use among the Greeks.

It was first used by the Lacedemonians, particularly those of Argos; afterwards it passed into Epirus, Lybia, Sicily, and the islands of Rhodes, Crete, &c.

DORIC MODE, in music, the first of the authentic modes of the ancients; its character is to be severe, tempered with gravity and joy; and is proper upon religious occasions, as also to be used in war.

It begins *D, la, sol, re*. Plato admires the music of the Doric mode, and judges it proper to preserve good manners, as being masculine; and on this account allows it in his commewealth.

DORING, or DARING, among sportsmen, a term used to express a method of taking larks by means of a clap-net and looking-glass.

DORMANT, in heraldry, is used for the posture of a lion, or any other beast, lying along in a sleeping attitude, with the head on the fore-paws; by which it is distinguished from the couchant, where though the beast be lying, yet he holds up his head.

DORMANT TREE, in architecture, signifies a window made in the roof of an house, or above the entablature, being raised upon the rafters.

DORMITORY, a gallery in convents or religious houses, divided into several cells, in which the religious sleep or lodge.

DORONICUM, leopard's bane, in botany, a genus of plants, producing compound, radiated flowers. The discous florets are hermaphrodite and funnel-shaped, and the rays are composed of several ligulated, spear-pointed female florets. These are succeeded, each by a single furrowed seed, covered with down, and contained in the calyx, which is slightly connivent.

The doricum officinarum grows naturally in Hungary and Switzerland, the roots of which are said to be an alexipharmic, and good against the

bites of venomous creatures; but modern practice gives it little credit in any such intentions, and is therefore much in disuse.

DORSAL, an appellation given to whatever belongs to the back. See DORSUM.

DORSAL MUSCLES are the muscles of the back and loins, which are for the most part common: there are of the extensors usually reckoned three on each side, viz. the sacrolumbaris, the longissimus dorsi, and the semispinosus: the flexors are three also, viz. the quadratus lumborum, the psoas parvus, and the intertransversales lumborum. See each under its proper head.

DORSAL NERVES. See NERVE.

DORSIFEROUS PLANTS, among botanists, such as are of the capillary kind, without stalks, and which bear their seeds on the backside of their leaves.

The word is formed from the Latin, *dorsum*, the back, and *fero*, to bear.

DORSTENIA, CONTRAYERVA, in botany, a genus of plants, which are destitute of a corolla; but the cup, which is a common involucre, contains several quadrangular perianthiums, with four filiform stamina each.

The seeds, which are roundish and solitary, are contained in a common fleshy receptacle. See the article CONTRAYERVA.

DORSUM, BACK, in anatomy, comprehends all the posterior part of the trunk of the body, from the neck to the buttocks. The back is furnished with several muscles, which are common to it with the loins, as the longissimus dorsi, the sacrolumbaris, and semispinosus; these are called extensors. See EXTENSOR.

To the back likewise belong the intertransversales lumborum, the quadratus lumborum, and the psoas. See the article INTERTRANSVERSALES, &c.

Its bones are the spina dorsi, ribs, and os sacrum. See SPINE, RIB, &c.

Dorsum is also used to denote the upper-side of the hand and foot, in contradistinction to the lower-side, called the palm and sole. See HAND and FOOT.

DORSUM NASI, the ridge of the nose. See NOSE.

DOSE, in medicine and pharmacy, the quantity of a medicine given at one time; or the proportion which the several ingredients of a compound medicine bear to each other.

DOSITHEANS, *Dosithei*, in church-history, a sect among the Hebrews, being one of the branches of the Samaritans. See the article SAMARITANS.

DOSSER, in military matters, a sort of basket, carried on the shoulders of men, used in carrying the overplus earth from one part of a fortification to another, where it is wanted.

DOSSIL, in surgery, lint made into a cylindric form, or resembling the shape of dates, or olive-stones, the size of which is very different. Dossils are used in dressing a disordered part, and are sometimes secured by a thread, tied round their middle.

DOUBLE CAST, in husbandry, a term used by the farmers for that method of sowing that does not dispense the necessary quantity of seed for a piece of land at one bout, but requires going over many places twice.

DOUBLE DESCANT, in music. See the article DESCANT.

DOUBLE Horizontal Dial, one with a double gnomon, one of which points out the hour on the outward circle, and the other shews the hour upon the stereographic projection drawn upon it. This dial not only finds the meridian, hour, &c. but shews the sun's place, rising and setting, declination, amplitude, altitude, and azimuth, with many other useful propositions.

DOUBLE FICHY, or FICHE, in heraldry, the denomination of a cross, when the extremity has two points, in contradistinction to *fiché*, where the extremity is sharpened away to one point.

DOUBLE LETTER, in grammar, a letter which has the force and effect of two. The Greeks have three of these, viz. Ζ, Ξ, Ψ; the Latins have two, X and Z; and most of the modern languages have the same.

DOUBLE PEDESTAL. See PEDESTAL.

DOUBLE PLEA, in law, is where the defendant in a suit alleges two several matters in bar of the plaintiff's action, when one of them is sufficient. This is not admitted in common law. Thus when a person pleads several things, the one having no dependance upon the other, such plea is accounted double, and will not be admitted; but where the things pleaded mutually depend on each other, and the party cannot have the last plea without the first, there the whole shall be received.

DOUBLE PLOUGH. See PLOUGH.

DOUBLE POINT, in the higher geometry. See CURVES of the second Order.

DOUBLE POSITION. See POSITION.

DOUBLE QUARREL, a complaint made by any clerk, or other, to the archbishop of a province, against an inferior ordinary for delaying justice in some spiritual cause, as to give sentence, institute a clerk, or the like.

DOUBLE VESSEL, in chemistry, is when the neck of one bolt-head or matrass is put and well luted into the neck of another, in order to refine and exalt spirits as high as can be. It is sometimes called a pelican, also a diota.

DOUBLET, among lapidaries, implies a counterfeited stone composed of two pieces of crystal, and sometimes glass, fastened together with proper colours between them, so as to appear the same to the

eye, as if the whole substance of the crystal had been tinged with those colours.

DOUBLING, in the military art, is the putting two ranks or files of soldiers into one.

DOUBLING, among hunters, who say that a hare doubles, when she keeps in plain fields, and winds about to deceive the hounds.

DOUBLING, in the manege, a term used of a horse, who is said to double his reins, when he leaps several times together, to throw his rider: thus we say, the ramingue doubles his reins, and makes pontleviss.

DOUBLING, in navigation, the act of sailing round a cape, point of land, &c. so as that the cape or point of land becomes between the ship and her former situation, or between any observer and the ship.

DOUBLING upon, in a sea-fight, is when part of one fleet, either by having a greater number of ships, or by taking the advantage of the wind with a superior skill, encloses part of the enemy's fleet between two fires, so that they are attacked on both sides; a circumstance which exposes them to the greatest danger, and usually throws them into confusion. See ENGAGEMENT and LINE.

DOUBLINGS, in heraldry, the linings of robes and mantlings in achievements.

DOUBLON, or DOUBLOON, a Spanish and Portuguese coin, being the double of a pistole. See PISTOLE.

DOUBTING, Dubitatio, the act of withholding our assent from any proposition, on suspicion that we are not thoroughly apprised of the merits thereof; or from not being able peremptorily to decide between the reasons for and against it.

DOUBTING, in rhetoric, signifies the debate of the mind with itself, upon a pressing difficulty. It is for the most part expressed by interrogation, though that is not necessary.

DOUCINE, in architecture, a moulding concave above and convex below, serving commonly as a cymatium to a delicate cornice. It is likewise called *gula*. See CYNAMATIUM and GULA.

DOVE, Columba, in ornithology. See PIGEON.

DOVE-TAILING, in carpentry, is the manner of fastening boards together by letting one piece into another, in the form of the tail of a dove. The dove-tail is the strongest of the assemblages or jointings, because the tenon or piece of wood which is put into the other, goes widening to the extreme, so that it cannot be drawn out again, by reason the extreme of tip is bigger than the line.

DOWAGER, Dotissa, a widow endowed, is a title applied to the widows of princes, dukes, earls, and persons of high rank only.

DOWER, that portion which the law allows a widow out of the lands of her husband, after his decease.

DOWLE-

DOWLE-STONES, in our old writers, the same with land-marks.

DOWRY, *Dos*, is properly the money or fortune which the wife brings her husband in marriage: it is otherwise called *maritagium*, marriage-goods, and differs from dower. See **DOWER**.

DOWRY is also used, in a monastic sense, for a sum of money given along with a maid, upon entering her in some religious order.

DOXOLOGY, an hymn used in praise of the almighty, distinguished by the title of greater and lesser.

The lesser doxology was anciently only a single sentence, without response, running in these words, "Glory be to the Father, and to the Son, and to the Holy Ghost, world without end, Amen." Part of the latter clause, "As it was in the beginning, is now, and ever shall be," was inserted some time after the first composition. Some read this ancient hymn, "Glory be to the Father, and to the Son, with the Holy Ghost." Others, "Glory be to the Father, in or by the Son, and by the Holy Ghost." This difference of expression occasioned no disputes in the church, till the rise of the Arian heresy; but when the followers of Arius began to make use of the latter, as a distinguishing character of their party, it was entirely laid aside by the Catholics, and the use of it was enough to bring any one under suspicion of heterodoxy. The doxology was used at the close of every solemn office. The Western church repeated it at the end of every psalm, and the Eastern church at the end of the last psalm. Many of their prayers were also concluded with it, particularly the solemn thanksgiving, or consecration prayer at the eucharist. It was also the ordinary conclusion of their sermons.

The greater doxology, or angelical hymn, was likewise of great note in the ancient church. It began with these words, which the angels sung at our Saviour's birth, "Glory be to God on high, &c." It was chiefly used in the communion service, and in men's private devotions. In the Mozarabic liturgy, it is appointed to be sung before the lessons on Christmas-day; and St. Chrysostom observes, that the Ascetics met together daily to sing this hymn. Both the doxologies have a place in the church of England, the former being repeated after every psalm, and the latter used in the communion service.

DRACHM, a Grecian coin, of the value of seven-pence three-farthings.

DRACO VOLANS, in meteorology, a fiery exhalation, frequent in marshy and cold countries.

It is most common in summer, and though principally seen playing near the banks of rivers, or in boggy places, yet sometimes mounts up to a considerable height in the air, to the no small terror of the amazed beholders; its appearance being that of an oblong, sometimes roundish, fiery body, with a

long tail. It is entirely harmless, frequently sticking to the hands and cloaths of people, without injuring them in the least.

DRACO, in astronomy, a constellation of the northern hemisphere, containing eighty stars, according to the following catalogue.

This was the dragon which Juno appointed to keep the golden apples in the orchard of the Hesperides, now thought to be the Cape de Verd islands; and, for his diligence and watchfulness, he was afterwards placed in heaven.

DRACOCEPHALUM, dragon's-head, in botany, a genus of plants, whose corolla consists of a single ringent petal. The tube is the length of the cup. The upper lip is obtuse and arched; and the lower divided into three segments. The germen is quadripartite, which afterwards becomes four ovato-oblong seeds, included in the calyx.

This genus comprehends the *moldivica* of Tournefort, a species of which is known in the English gardens, by the name of balm of Gilead, or Turkey balm.

DRACONTIUM, dragon, in botany, a genus of plants, whose flower consists of a cymbiform coriaceous spathe, which is large and univalvular, with a pentapetalous concave corolla, containing seven linear depressed stamina.

The fruit is a roundish berry, inclosing a number of seeds.

DRACUNCULI, in medicine, small long worms, which breed in the muscular parts of the arms and legs, called Guinea-worms.

This distemper is very common in Guinea, and principally among the natives; Kempfer found it also at Ormuz, upon the Persian gulph, and likewise in Tartary. Dr. Tawne, in his Treatise of the Diseases of the West-Indies, informs us, that this distemper is not so frequent any where as on the Gold Coast, at Anamboe, and Cormantyn.

The worm is white, round, and uniform, very much resembling white round tape or bobbing. It is lodged between the interfices and membranes of the muscles, where it insinuates itself, sometimes exceeding five ells in length. It occasions no great pain at the beginning; but at such times as it is ready to make its exit, the parts adjoining to the extremity of the worm, where it attempts its exclusion, begin to swell, throb, and be inflamed: this generally happens about the ankle, leg, or thigh, and rarely higher.

The countries where this distemper is observed, are very hot and sultry, liable to great droughts, and the inhabitants make use of stagnating and corrupted water, in which it is very probable that the ova of these animalcula may be contained; for the white people who drink this water, are obnoxious to the disease as well as the negroes.

The surgeons seldom attempt to extract this worm by making an incision; but as soon as they perceive the tumour rise to a competent bulk, they endeavour to bring it to a suppuration, with all convenient expedition; and then the head of the worm discovers itself, which they secure, by tying it to a bit of stick or cotton, that it may not draw itself up again: thus they continue to roll it round the stick, sometimes one inch, sometimes two or more, each day, taking great care not to break the worm, else it will be very difficult to recover the end of it again; and an abscess will be formed, not only at the suppurated part, but likewise through the whole winding of the muscles, where the dead putrifying worm remains, which generally occasions very obdurate ulcers. During the extraction of the worm, the patient should be plied with bitter aloetic and other anthelmintic medicines, in order to dislodge the worm the sooner from his tenement. When the worm is totally extracted, the remaining ulcer may be treated in the same manner as other common ulcers; nor does any farther inconvenience remain in the parts of which it had possession. This disease, simply considered, very rarely, if ever, proves mortal.

DRACUNCULI is also used for a disease in children, arising from little worms called by that name. See the article **WORM**.

DRACONS, dracunculus, in botany, formerly a distinct genus of plants; but now comprehended by

by Linnæus among the arums; for its generical characters and medicinal virtues, see the article ARUM.

DRAGANT, the same with tragacanth. See the article TRAGACANTH.

DRAGOMAN, DROGMAN, or DRUGGERMAN, a name given in the Levant to the interpreters kept by the ambassadors of Christian nations residing at the Porte, to assist them in treating of their masters affairs.

DRAGON, *Draco*, in zoology, an animal called also the flying lizard, being furnished with two lateral, membranaceous, and radiated wings: it is a true lizard, with a naked and four-legged body, and a long tail: though there are not wanting some who deny the existence of any such animal.

DRAGON'S BELLY, in astronomy. See the article VENTER DRAGONIS.

DRAGON'S BLOOD, *Sanguis Draconis*, in natural history, a moderately heavy resin, of a red colour, brought from the East-Indies. There are two sorts of it; one in small oval drops or tears, of a fine deep red, which is heightened into a crimson on grinding them into powder; the other is in larger masses, apparently composed of tears: of these, some are of a pale dull red, others of a deep one, not at all inferior to the drop sort.

The drops and the lumps are supposed to be the produce of two different trees. The lump sort is said to exude from the trunks of certain palms growing in the Madeira and Canary islands; the drops to be artificially extracted from the fruit of a tree. According to Kemper, the fruit is laid upon a kind of hurdle, over a large vessel half full of water. The whole being lightly covered, the water is made to boil, when the fruit being softened by the steam, a red juice, which was not discoverable in it before, appears upon the surface: this is scraped off upon flag leaves, and exposed to the air to dry. The same author informs us, that some of the preparers of this commodity boil the fruit in water till all the colouring particles are extracted or melted out; after which, the aqueous fluid is evaporated, till the remainder begins to thicken, when it is further excited upon flag leaves, as before.

This drug has been sometimes counterfeited with artificial compositions, coloured with the true dragon's blood, or Brazil wood: these are distinguished by their either dissolving in water like gums, or crackling, and not burning in the fire.

The genuine dragon's blood is not acted upon by water, or at most communicates to it only a slight yellowish tinge: laid on a red-hot iron, it readily melts, catches flame, and emits an acid fume approaching to that of benzoin. It dissolves, but not perfectly, in rectified spirit of wine, and tinges a large quantity of the menstruum of an elegant blood-red colour: it dissolves readily in oils, and tinges them of a pretty deep red, but somewhat less beauti-

ful than the colour of the spirituous tincture, and considerably less so than that which anchusa imparts to oil.

The spirituous tincture stains cold marble of a bright flesh colour; to warm marble it gives a deeper red, in proportion to the degree of heat. Mr. du Fay observes, that by this one ingredient, with the addition of a little pitch for the darker colours, all the various shades of red may be obtained, from the lightest to the deepest; that it does not sink near so far into cold as into hot marble; and that the not sinking is rather an advantage than an imperfection, as the colours which sink must also spread, so as to render the drawing of fine designs impracticable; that the best way of obtaining beautiful reds from dragon's blood is, to put the powdered resin into spirit of wine over the fire, and apply on the marble with a pencil the finer part of the solution which rises up about the sides of the vessel, adding fresh spirit in proportion to the evaporation, till the dragon's blood yields no more tincture.

This resin, in substance, has no smell or taste: when dissolved, it discovers a slight degree of pungency. It is usually looked upon as a gentle incrustant, desiccative, and restraining; and sometimes prescribed in these intentions against alvine and uterine fluxes, and ulcerations both internal and external.

DRAGON-FLY, the English name of the libella. See the article LIBELLA.

DRAGON'S HEAD and TAIL, the two nodes of the moon. See the article NODE.

DRAGON-SHELL, the English name of a species of concamerated patella, with its rostrum very much bent. See the article PATELLA.

DRAGONNE, in heraldry, a lion dragonnée is where the upper half resembles a lion, the other half going off like the hinder part of a dragon. The same may be said of any other beast as well as a lion.

DRAGOON, in war, a kind of soldier, who acts on horseback, but without boots, and fights on foot generally; they are posted in the front of the camp, and march first to the charge. As infantry, they have sergeants, and as cavalry, cornets; their arms are a sword, firelock, and bayonet; and when they march on foot, their officers bear the pike and the sergeant the halbert. Menage derives the word from the Latin *dracnarius*, used by Vegetius to signify soldiers; but it is more probably derived from the German *tragen* or *dragen*, signifying to carry, as being infantry carried on horseback.

DRAGOON, in ornithology, the name of a small kind of carrier-pigeon, called *columba tabellaria minima*, by Moore. It is a bastard-breed between the two species of pigeons called the horseman and the tumbler. They are very good breeders; and as they are lighter than the horseman, they are supposed to be more expeditious in flight for a few miles;

miles; but the horseman excels them in greater lengths.

DRAINING of lands. See the article **FEN**.

DRAINS, a name given, in the fen-countries, to certain large cuts or ditches, of twenty, thirty, nay sometimes forty feet wide, carried through the marshy ground, to some river, or other place, capable of discharging the water they carry out of the fen-lands. See the article **FEN**.

DRAKE, in ornithology, the male of the duck-kind. See **DUCK**.

DRAM, or **DRACHM**, in commerce, a small weight. See **WEIGHT**.

DRAMA, a poem containing some certain action, and representing a true picture of human life, for the delight and improvement of mankind.

The principal species of the drama are two, comedy and tragedy. Some others there are of less note, as pastoral, satire, tragi-comedy, opera, &c. See the articles **TRAGEDY**, **COMEDY**, &c.

The primary parts of the drama as divided by the ancients, are the *protasis*, *epitasis*, *catastasis*, and *catastrophe*. The secondary parts are the acts and scenes. The accessory parts are the prologue, chorus, mimus, and epilogue, which pointed out the use of the piece, or conveyed some other notice to the audience in the poet's name. See **PROTASIS**, **PROLOGUE**, **CHORUS**, &c.

The drama, says Vossius, owes its rise to the days of festivity; for in ancient times, it was usual for men, when they gathered in the fruits of the earth, to meet together, that they might sacrifice to the Deity, and unbend their minds from the fatigues of the harvest. Hence arose two sorts of poetry, the one grave, in praise of the gods; the other jocose and full of lampoon, against one another. Thus, from the former arose tragedy, and from the latter, satire, comedy, and mimicry.

The drama, in some circumstances, is superior to epic poetry, particularly in action; for in the drama, the persons themselves are introduced, every thing is transacted in our sight, and our eyes and ears at once are gratified. Besides, the action in the drama is much more compendious than in the epic: it takes up less time, and therefore requires more art to conduct it. It excites in the mind more rapid commotions, and consequently makes the pleasure and admiration more intense. For which reasons Aristotle gives the preference to the drama; not that he reckons it more noble in general than the epic, for that would be contrary to truth and reason, but only as far as its sphere extends.

According to the Abbé du Bos, tragic poets ought to place their scenes in times remote from that in which they live; but that comedy, on the contrary, ought to be fixed in the very places and times in which it is represented; its design being to make us laugh at the expence of ridiculous persons, in order to purge us of those faults it exposes. Now we can-

not distinguish nature so easily, when she appears in strange customs, manners, and apparel, as when she is clad, as it were, after our own fashion; whereas we always distinguish human nature in the heroes of tragedies, whether their scenes be at Rome or Sparta, by reason only great virtues or great vices are there represented.

The dramatic poetry of the Romans was at first divided into three sorts, tragedy, satire, and comedy; which were afterwards subdivided into several species. They had two species of tragedies, viz. the *tragediæ palliatæ*, in which the personages, manners, and drefs, were entirely Greek; and the *tragediæ prætextatæ*, or *pretextæ*, wherein the personages and manners were Roman. The satire was a kind of pastoral poetry, which some authors assert to have held a kind of middle rank between tragedy and comedy; which is almost all we know of it. Comedy, in like manner as tragedy, was divided first into two species, viz. the Greek, or *palliata*, and the Roman, or *togata*, by reason of the introducing plain citizens into the latter, whose drefs was called *toga*. The Roman comedy was again subdivided into four species; the *togata*, properly so called, the *tabernaria*, the *attellana*, and the *mimus*. Pieces of the first sort were very serious, and admitted even of persons of distinction, for which reason they were sometimes called *prætextatæ*. The second were comedies of a less serious nature, and took their name from *taberna*; which strictly signified a place of rendezvous, proper for assembling persons of different conditions, whose characters were played off in those pieces. The *attellana* was a kind of piece very like the Italian comedies; that is, those whose dialogues are not written. The actor, therefore, of the *attellana* performed his part just as he pleased. The *mimus* resembled our farces, and the actors thereof performed always bare-foot: whereas, in tragedy, they wore a sort of shoe, or boot, called *cothurnus*; and, in other species of comedy, another kind called *focuss*.

For the laws of the drama, see the articles **UNITY**, **ACTION**, **CHARACTER**, **FABLE**, &c.

DRAMATIC, in poetry, an epithet given to pieces written for the stage.

DRANK, in husbandry, a term used to denote wild oats, which never fail to infest worn-out lands; so that when ploughed lands run to these weeds and thistles, the farmer knows it is high time to fallow them, or else to sow them with hay-feed, and make pasture of them.

Some, indeed, destroy the drank, by sowing the lands with beans, and letting loose sheep upon them when young. This must be done in dry weather, and the sheep eat up the drank and other weeds, without touching the beans.

DRAPERY, in sculpture and painting, implies the representation of the cloathing of human figure,

and also hangings, tapestry, curtains, and most other things that are not carnations or landscapes.

The art of drapery consists, 1. In the order of the folds or plaits, which ought to be so managed, that you may easily perceive what it is they cover, and distinguish it from any thing else. Again, the folds ought to be large, as breaking and dividing the sight the less; and there should be a contrast between them, otherwise the drapery will be stiff. 2. In the quality of the stuffs; for some make their folds abrupt and harsh; others more soft and easy: the surface of some have a lustre, others are flat and dead; some are fine and transparent, others firm and solid. 3. In the variety of colours, which, when well managed, makes the greatest beauty of painting; all not being equally amicable and friendly with respect to each other, and some never to be placed near certain others.

M. De Piles observes, that drapery must never be made to adhere to the parts of the body; that a great motion and lightness of the drapery are only proper in figures in great agitation, or exposed to the wind; and that the nudities of the figures should always be designed, before the painter proceeds to the draperies.

DRASTIC, in physic, an epithet bestowed on such medicines as are of present efficacy, and potent in operations; and is commonly applied to emetics and cathartics.

DRAUGHT, or **DRAFT**, in architecture, the figure of an intended building, described on paper, in which is laid down, by scale and compasses, the several divisions and partitions of the apartments, rooms, doors, passages, &c. in their due proportion to the whole building.

It is customary, and also exceedingly convenient, for any person, before he begins to erect a building, to have designs or draughts drawn upon paper or vellum, wherein the ichnography or ground-plot of every floor or story is delineated; as also the form or fashion of each front, with the windows, doors, ornaments, in an orthography, or upright. Sometimes the several fronts, &c. are taken and represented in the same draught, to shew the effect of the whole building, which is called scenography, or perspective. See the article **SCENOGRAPHY**.

DRAUGHT-COMPASSES, are such as have moveable points to draw fine draughts in architecture.

DRAUGHT, in trade, called also **CLOFF** or **CLOUGH**, is a small allowance on weighable goods, made by the king to the importer, or by the seller to the buyer, that the weight may hold out when the goods are weighed again.

The king allows 1 lb draught for goods weighing no less than 1 C wt. 2 lb for goods weighing between 1 and 2 C wt. 3 lb for goods weighing between 2 and 3 C wt. 4 lb from 3 to 10 C wt. 7 lb from 10 to 18 C wt. 9 lb from 18 to 30, or upwards.

DRAUGHT-HOOKS, are large hooks of iron, fixed on the cheeks of a cannon-carriage, two on each side, one near the trunnion-hole, and the other at the train, distinguished by the name of fore and hind draught-hooks. Large guns have draught-hooks near the middle truncheon, to which are fixed the chains that serve to keep the shafts of the limbers on a march. The fore and hind hooks are used for drawing a gun backwards or forwards by men with strong ropes, called draught-ropes, fixed to these hooks.

DRAUGHT-HORSE, in farming, a sort of coarse made horse, destined for the service of the cart or plough. In the choice of these horses, for what is called the slow draught, they are to be chosen of an ordinary height; for otherwise, when put into the cart, one draws unequally with the other, and the tall ones hang upon the low ones. The draught-horse should be large bodied, and strong loined, and of such a disposition as rather to be too dull than too brisk; and rather to crave the whip than to draw more than is needful. Mares are the fittest for this use for the farmer, as they will be kept cheap, and not only do the work, but be kept breeding, and give yearly increase of a foal of the same kind, and fit to be bred to the same purposes. They should have a good head, neck, breast, and shoulders: for the rest of the shape, it is not of much consequence, only for breeding; the mare should have a large belly; for the more room the foal has in the dam, the more fit he will be for that employ. See the article **FOAL**.

DRAW-BACK, in commerce, certain duties, either of the customs or of the excise, allowed upon the exportation of some of our own manufactures; or upon certain foreign merchandise, that have paid duty on importation.

DRAW-BRIDGE, a bridge made after the manner of a floor, to draw up, or let down, as occasion serves, before the gate of a town or castle.

A draw-bridge may be made after several different ways, but the most common are made with plyers, twice the length of the gate, and a foot in diameter. The inner square is traversed with a cross, which serves for a counterpoise; and the chains which hang from the extremities of the plyers to lift up or let down the bridge, are of iron or brass.

In navigable rivers it is sometimes necessary to make the middle arch of bridges with two moveable platforms, to be raised occasionally, in order to let the masts and rigging of vessels pass through. This kind of draw-bridge is represented in the plate; where A B is the width of the middle arch; A L and B L, the two piers that support the draw-bridge N O, one of the platforms of which is raised, and the other let down, having the beam P Q for its pleyer. To N O are suspended two moveable braces E H, E H, which, resting on the support E, press against

against the bracket M, and thereby strengthen the draw-bridge. These braces are conducted to the rest by means of the weight S, pulling the chain SLE.

DRAW-GEAR, denotes any kind of harness for draught horses.

DRAWER of a Bill of Exchange, the person who draws the bill upon his correspondent.

DRAWING, in general, denotes the action of pulling out, or haling along: thus we read of tooth-drawing, wire-drawing, &c. See **TOOTH** and **WIRE**.

DRAWING, the art of representing the appearances of objects by imitation, or copying without the assistance of mathematical rules.

The general precepts for drawing, are as follow:
1. Begin with plain, geometrical figures, as lines, angles, triangles, polygons, arches, circles, ovals, cones, cylinders, and the like, being the foundation of all other proportions. The circle is of use in the several orbicular forms, as the sun, moon, globes, &c. the oval in giving a just proportion to the face and mouth; and the square confines a picture you are to copy, &c. the triangle is of use in drawing a side or half face; angles and arches in perspective, and the polygon in ground-plots, fortifications, &c. the cone, in spires, steeples, tops of towers, &c. the cylinder, in columns, pillars, pilasters, &c. See the article **PERSPECTIVE**.

2. Having brought your hand to be fit and ready in general proportions, accustom yourself to give every object its due shade, according to its concavity or convexity, and to elevate or depress the same, as the object appears either nearer or farther off the light. See the articles **PROPORTION**, **DESIGN**, and **SHADE**.

3. The second practice of drawing consists in forming fruits, as apples, pears, cherries, &c. with their leaves; the imitation of flowers, as roses, tulips, carnations, &c. herbs, trees, &c. of different kinds.

4. The third, in the imitation of beasts, fowls, fishes, &c.

5. The fourth practice of drawing consists in the imitation of the body of men, with all its lineaments, as head, nose, eyes, ears, cheeks, arms, and shadows, all exactly proportioned, both to the whole, and to one another.

6. The fifth is in the drapery, in the imitation of cloathing, and artificially setting off the outward coverings, habit, and ornaments of the body, either of cloth, stuff, silk, or linen, in their natural and proper folds. See **DRAPERY**.

7. In drawing of all the forms before-mentioned, it is requisite to be first perfect in the laying down the exact proportion; secondly, in the general or outward lines, before you proceed to shadowing, or trimming the work within.

8. In mixed and uncertain forms, where the cir-

cle, square, &c. will be of no use, but only in the idea thereof in your own fancy, as horses, oxen, and the like, you must do it by judgment, and to gain the true proportions by assiduous practice: thus, having the shape of the thing in your mind, first draw it rudely with a coal; then, with more exactness, with a lead or pencil; then peruse it well, and mend it in those parts you have erred in, according to the idea you carry in your mind. When it is mended by your own judgment, compare it with some good pattern of the same kind, and amend it by that.

9. Having good copies to draw after, learn to reduce them to other proportions, either larger or smaller, and this by frequent practice.

10. Let a perfection in drawing be attained by diligent exercise, and the instruction of a good master, before there be any attempts as to colouring and painting; for the former being attained, the rest will be easily understood, and gained by frequent practice.

DRAWING-MEDICINES, those more usually called epispastics and ripeners.

DRAWING, among sportsmen, the beating the bushes after a fox.

Fine DRAWING, among taylor's, the art of sewing up button-holes, or any rents in cloth, in so nice a manner, as that they cannot be discovered from the entire part of the cloth.

DRAY, a kind of cart used by brewers for carrying barrels of beer or ale; also a sledge drawn without wheels.

DRAY, among sportsmen, denotes squirrel-nests built in the tops of trees.

DREIN, or **DRAIN**, in military affairs, a small fosse or trench, formed to draw the water from the ditch which surrounds the place besieged: the ditch is afterwards filled with fascines, gabions, hurdles, &c. to facilitate the passage of the troops across it. See **DITCH**.

DRENCH, among farriers, a physical potion for horses. The ingredients for this purpose are to be beat coarsely, and either mingled with a decoction, or with wine. Then infuse it all about a quarter of an hour, and give it to the horse with a horn, after he has been tied up two hours to the rack.

DRESSING of Hemp or Flax. See **HEMP** and **FLAX**.

DRESSING of Ores, the preparing them, as they come rough from the mine, for the working by fire. This is done several ways in different countries, and in respect to the different ores of different metals. In Devonshire they have a very easy method, which is so expeditious, and so good for all the purposes, that it is worthy copying in other places. After the ore is dug, it is tossed up by hand from shamble to shamble by the shovel men in the mine, and drawn up in buckets by a winch at the top of a shaft. As soon as the whole quantity for one dressing is brought up,

the large stones are broken, and the whole is then carried to the mills, where one horse turns a wheel that moves the machines for powdering a great quantity of it; these are called the stamping or knocking mills. The ore is unloaded at the head of the pails or entrance into these mills; this pass is made of two or three bottom boards, and two side boards, in form of a hollow trough, and stands in a slanting direction. The ore by its own weight is carried down this trough, and lodges itself in the coffer. The coffer is a long square box made of the firmest timber, and of three feet long, and a foot and a half broad: the ore is not suffered to fall into this all at once, but is stopped over the mouth of the trough by a cross board, where a cock turns into it a quantity of water at the same time, which washes down just as much of the ore with it into the trough as there ought to be. In this coffer there are three lifters placed between two strong board leaves, having two braces or thwart pieces on each side to keep them steady, and a frame with stamp heads. These heads are of iron, and weigh about thirty or forty pounds a-piece, and serve to break the lumps of ore in the coffer.

The lifters are about eight feet long, and half a foot square. They are always made of heart of oak, and have as many timbers or guiders between them; they are lifted up in order, by a double number of toppits, which are fastened to as many arms passing diametrically through the greatest beam, which is either turned by the wheel and horse, or where there is conveniency of water, by an over-shot water-wheel on two boulders. The toppits exactly, but easily, meet with the tongues, which are so placed in the lifters, as that they easily slide from each other, and suffer the lifters to fall with great force on the ore in the trough. The frequent pounding of these soon reduces the large masses into a sort of sand, which is washed out of the trough by the continual current of the water from the cock through a brass grate, placed at one end of the coffer between two iron bars.

The powdered ore is conveyed out of the trough into the launder, which is a trench cut in the floor of eight feet long, and ten feet over; this is stopped at the lower end with turf, so that the water is all suffered to pass away, and the powder of the ore is stopped. Thus the launder by degrees fills up with the dressed ore; and this is removed out with shovels, as occasion requires. The launder is divided into three parts, the forehead, the middle, and the tail; that ore which lies in the forehead, that is, within a foot and a half of the grate, is always the richest and best, and is laid up in a heap by itself; the middle and tail afford a poorer ore; and these are sometimes laid up in separate heaps; sometimes thrown into one heap together.

DRESSING, in surgery, the treatment of a wound or any disordered part. The apparatus of dressing

consists of dossils, tents, plasters, compresses, bandages, bands, ligatures, and strings.

DRIFT of the *Forest* is an exact view and examination taken at certain times to know what beasts are there, in order that none may come on the forest but such as have right; and that the forest be not overcharged with beasts.

DRIFT, in mining, a passage cut out under the earth, betwixt shaft and shaft, or turn and turn; or a passage or way, wrought under the earth, to the end of a meer of ground, or part of a meer.

DRIFT, in navigation, the line upon which a ship drives in a storm with her side to the wind, when it blows so violent as to prevent her from being able to carry any sail, or only enough to keep her sufficiently inclined to one side, that the masts may not carry away her masts by violent rocking: or, drift is the angle which the line of her motion makes with the keel in such a situation when her prow is in the middle between the points of the compass, to which she comes up and falls. See the article **TRYING**.

DRILL, in mechanics, a small instrument for making such holes as punches will not conveniently serve for.

Drills are of various sizes, and are chiefly used by smiths and turners.

DRILL, or **DRILL-BOX**, a name given to an instrument for sowing land in the new method of horse-hoeing husbandry. It plants the corn in rows, makes the channels, sows the seeds in them, and covers them with earth when sown; and all this at the same time, and with great expedition. The principal parts are the seed-box, the hopper, the plough and its harrow, of all which the seed-box is the chief. It measures, or rather numbers, out the seed, which it receives from the hopper, and is for this purpose an artificial hand; but it delivers out the seed much more equally than can be done by a natural hand. See the article **PLOUGH**.

DRINK, a part of our ordinary food in a liquid form, serving to dilute and moisten the dry meat.

DRIPS, in architecture. See the article **LARRIER**.

DRIVER, in naval affairs, an oblong sail hoisted occasionally to the mizen-peak when the wind is very fair; the lower corners of it are extended by a boom or pole, which is thrust out across the ship over the quarter. See **MIZEN** and **QUARTER**.

DRIVERS, among sportsmen, a machine for driving pheasant-powts, consisting of good strong ozier-wands, such as the basket-makers use; these are to be set in an handle, and twisted or bound with small oziers in two or three places.

With this instrument the sportsman drives whole eyes of young powts into his nets.

DRIVING, among sportsmen, a method of taking pheasant-powts. It is thus performed: the sportsman finds out the haunts of these birds; and having fixed his nets there, he calls them together by a pheasant-call,

call, imitating the voice of the dam : after this he makes a noise with his driver, which will make them run a little way forward in a cluster ; and this he is to repeat till he has made sure of them, which an expert sportsman never fails to do, by driving them into his nets.

DRIVING, in metallurgy, is said of silver, when in the operation of refining, the lead being burnt away, the remaining copper rises upon its surface in red fiery bubbles. See the article **SILVER**.

DROCK, in husbandry, the upright piece of timber on the right side of a plough's tail, to which is fixed the earth-board. See **PLOUGH**.

DROMEDARY, *Dromedarius*, a large animal of the camel-kind, with only one hump on its back : it is taller than the horse, and has a much longer and slender neck : its ears are short, and the upper lip is divided in the manner of that of the hare. It is a native of Asia, and more used for riding on, than for carrying heavy loads.

DROMEUS, a name given by the ancients to two very distinct animals, the stag and dromedary.

DRONE, in the history of insects, a kind of male bee, larger than the common working or honey-bees : it is so called from its idleness, as never going abroad to collect either honey or wax. See **BEE**.

DRONE-FLY, a two winged insect, extremely like the common drone-bee, whence also the name.

DROPS, in architecture, an ornament in the Doric entablature, representing drops, or little bells, immediately under the triglyphs.

DROPSY, in medicine, a preternatural collection of extravasated aqueous serum, which greatly distends the vessels in any part of the body.

This disease may therefore happen in whatever part the vessels destined for the conveyance of the serum are found ; that is, either in the whole habit of the body, or in any particular part thereof.

Thus a dropsy may arise from a sordid collection of water, either between the external integuments of the head ; between these and the cranium ; between the cranium and the membranes of the brain ; between these membranes and the duplicatures ; between these duplicatures and the brain ; between the foldings of the brain ; and, lastly, in its cavities, but yet without producing immediate death.

In the cure of a dropsy the following intentions are to be pursued.

First, to produce a due fluidity and motion to the lymph, whether it is water or serum, of the bilious, ichorous, or bloody kind.

Secondly, to evacuate the waters already discharged into the cavities of the body.

Thirdly, to remove the weakness of the viscera, whether this weakness is the cause or the effect of the dropsy.

The fluidity of the lymph is procured, by removing those causes which prevent such a fluidity ;

which are, first, the too languid force of the vital powers subservient to circulation ; secondly, the compression, rupture, or obstruction of the vessels ; and, thirdly, the excessive or preternatural viscosity of the fluids.

With respect to the too languid force of the vital powers subservient to circulation, this is most commodiously removed by cardiacs, corroboratives, and medicines of a stimulating quality, which, if the patient is not afflicted with a violent thirst, are to consist of aromatic, saline, oleous, and hot substances ; which may be easily prepared in the various forms of electuaries, mixtures, medicated wines, medicated ales, pills, decoctions, syrups, &c.

DROP-WORT. See **FILIPENDULA**.

Water DROP-WORT, in botany. See the article **OENANTHE**.

DROSERA, sun-dew, in botany, a genus of plants, whose flower consists of a monophyllous persistent calyx, cut in five sharp-points. The corolla is funnel-shaped, and composed of five obtuse subovate petals, with the same number of stamina.

The fruit is an oval unilocular capsule, containing a great number of very small seeds.

DROWNING, the act of suffocating, or being suffocated, by water.

Naturalists and physicians furnish us with divers well attested instances of surprising recoveries of persons drowned. It is certain from repeated dissections made on persons drowned, that they generally have less water in their stomachs than if they had voluntarily drank a considerable quantity : whence it does not seem expedient to hang the drowned person by the heels, a position that must prove uneasy as soon as the humours of the body should resume their ordinary motion. In order to know whether the person has swallowed too much water, or not, and to make him vomit it up if he has, it is proper to put him in a tun open at both ends, which is to be rolled in different directions ; or the bearded end of a feather should be introduced into the oesophagus. After taking off the cloaths of the drowned person, we ought, with the utmost expedition, to shelter him from the impressions of the cold air, and begin to warm him by wrapping him up with cloaths and coverings : to do this more effectually, he is afterwards to be put into a pretty warm bed, applying also to his body hot napkins and cloths. A hot scorching sun, to which drowned persons have been exposed, and hot baths, have produced the same happy effects.

The great intention to be pursued is to put the solid parts of the machine in action, that thus they may restore the motion of the fluids : in order to this, the drowned person should be agitated in various directions, in a bed, in the arms of persons of sufficient strength.

Spirituuous liquors or warm urine should be poured into his mouth, and some persons prescribe a decoction

tion of pepper and vinegar, as a gargarism; we must also attempt to irritate the internal fibres of the nose, either by volatile spirits, and by the liquors used in apoplectic cases; or by tickling the nerves of the nostrils with a bearded feather, or by blowing through a quill, snuff, or some other more powerful sternutatory. One of the means frequently used with success, is to blow warm air, by means of a pipe, into their mouths; or to introduce it by a pair of bellows; or, by injecting warm clysters, to irritate the intestines: the smoke of tobacco conveyed into the intestines, by means of a tobacco-pipe, is much recommended. Venæsection is by no means to be neglected; and perhaps most successfully in the jugular vein; and when all these measures prove unsuccessful, the last recourse is bronchotomy. See the article BRONCHOTOMY.

DRUG, a general term for goods of the druggist and grocery kinds, especially for those used in medicine and dying.

DRUGGET, in commerce, a stuff sometimes all wool, and sometimes half wool and half thread, sometimes corded, but usually plain.

DRUIDS, the priests among the ancient Britons and Gauls.

The word is formed from the Celtic, *deru*, an oak; because they held that tree in the highest veneration.

Their antiquity is esteemed equal to that of the Brachmans of India, the Magi of Persia, and the Chaldees of Babylon. And whoever considers the surprising conformity of their doctrine, will find sufficient reason to think that they all derived it from the same hand, we mean from Noah and his immediate descendants, who carried it with them at their dispersion; for it cannot be supposed that the British druids derived their doctrine from any foreign sect, to whom they were absolutely unknown.

But the druids were not contented with the power annexed to the priesthood; they introduced religion into every transaction both public and private, so that nothing could be done without their approbation; and by this means their authority was rendered almost absolute. They elected the annual magistrates of every district, who should have enjoyed, during that term, the supreme authority, and sometimes the title of kings; but they could not even call a council without their approbation and advice: so that, notwithstanding their pretended authority, they were in reality the creatures and slaves of the druids.

They exercised the same arbitrary power in their courts of justice; and whoever refused to submit to their decisions, were excluded from the public sacrifices, which was considered as the greatest punishment that could be inflicted. It must however be acknowledged, that their administration of justice has always been celebrated for its impartiality. The sole management and instruction of youth was also committed to them, except the training them up in

the art of war; for both they and their disciples were not only exempted from going to war, but likewise from all kind of tribute.

Their garments were remarkably long; and, when employed in religious ceremonies, they always wore a white surplice. They generally carried a wand in their hands, and wore a kind of ornament enshafed in gold about their necks, called the druid's egg. Their necks were likewise decorated with gold chains, and their hands and arms with bracelets: they wore their hair very short, and their beards remarkably long.

They were all subordinate to a chief or sovereign pontiff, styled the arch-druid, chosen from among their fraternity by a plurality of voices; but, in case of a competition too powerful to be decided by a majority, the contest was determined by the sword. He enjoyed his supremacy for life, had power to inspect the conduct of kings, and either to elect or depose whenever he pleased.

It was one of the maxims of their religion, not to commit any thing to writing; but deliver all their mysteries and learning in verses composed for that purpose; and these were in time multiplied to such a number, that it generally took up twenty years to learn them all by heart. By this means their doctrines appeared more mysterious by being unknown to all but themselves; and having no books to recur to, they were the more careful to fix them in their memory.

But what had still a more direct tendency to impose on the public, was their pretended familiar intercourse with the gods. And, in order to conceal at once their own ignorance, and render the imposition less susceptible of detection, they boasted of their great skill in magic, and cultivated several branches of the mathematics, particularly astronomy. The latter they carried to some degree of perfection; for they were able to foretell the times, quantities, and durations of eclipses; a circumstance which could not fail of attracting reverence from an ignorant multitude, who were persuaded that nothing less than a supernatural power was sufficient to make such astonishing predictions: they also studied natural philosophy, and practised physic.

DRUM, a military musical instrument, used principally amongst the foot, to call the soldiers together, direct their marches, attacks, and retreats. The body of the drum is of a very thin oak, bent into a cylinder, and covered with parchment, which is strained or braced, more or less, according to the height or depth of the tone required, by strings, and struck with sticks. The height of the drum is equal to its breadth, which does not exceed two feet and an half, because no skins can be procured to cover bigger.

There are also drums whose bodies are brass, called kettle-drums, which are rounded in the bottom like a basin; they are used among the horse:

to be played on; they are laid across the shoulders of the horse before the drummer, who, with a variety of singular gestures, beats them with two little iron bars with balls at the end; their sound is softer and more agreeable than that of the common drum, and these are oftener used in operas, oratorios, tragedies, and concerts. There are divers beats of the drum, as the chamade, charge, march, double march, assemblée, retreat, &c.

DRUM, or **DUMMER**, he that beats the drum, of whom each company of foot has one, and sometimes two. Every regiment has a drum-major, who has the command over the other drums.

DRUM of the Ear, in anatomy. See **TYPANUM**.

DRUM, in architecture. See **TAMBOUR**.

DRUNKENNESS, *Ebrietas*, physically considered, consists in a preternatural compression of the brain, and a discomposure of its fibres, occasioned by the fumes or spirituous parts of liquors.

DRUPE, among botanists, a kind of pericarpium, consisting of a soft, fleshy, and succulent pulp, with a nucleus, or kernel in its center.

DRY MEAT, in the manege, is used for corn and hay. After taking the horse from grass he is housed, and put to dry meat.

DRYADS, *Dryades*, in the heathen theology, a sort of deities, or nymphs, which the ancients thought inhabited groves and woods. They differed from the Hamadryades; these latter being attached to some particular tree, with which they were born, and with which they died; whereas the Dryades were goddesses of trees and woods in general.

DUCAT, a coin current in Germany and other countries abroad, for the different values of which see **EXCHANGE**.

DUCATOON, a silver coin, likewise frequent in several parts of Europe.

DUCK, *Anas*, in ornithology, a genus of birds sufficiently known.

There are two sorts of ducks common in England, the tame and wild; the first of which is very beneficial to husbandmen, and at the same time requires no charge to keep, living on lost corn, worms, snails, &c. Indeed once a year this fowl is a great layer of eggs; and when she sits, must be carefully fed with barley or other grain. As to the ducklings, they are fed in the same manner as goslings, and may be fattened in three weeks time, by giving them any kind of pulse or grain, and plenty of water.

DUCT, or **DUCTUS**, in general, denotes any tube or canal.

It is much used by anatomists, who mention the adipose ducts, concerning the reality of which authors are not agreed; the thoracic, or chyliferous duct; the excretory ducts of the glands; the hepatic duct, or porus biliaris; the salival ducts; the lachrymal ducts; the ductus communis choledochus,

&c. concerning all which it is to be observed, that their use is to convey certain animal fluids secreted in the glands of the parts to which they severally belong: thus it is, the salival ducts discharge the saliva, or pellucid liquor, secreted in the glands of the mouth; and so of the rest.

DUCTILITY, in physics, a property of certain bodies, whereby they are capable of being expanded or stretched forth, by means of a hammer, press, &c.

The vast ductility of some bodies, especially gold, is very surprising. See **DIVISIBILITY**.

DUEL, is a single combat, at a time and place appointed, in consequence of a cartel or challenge.

The word is derived from the Latin, *duellum*, *quasi duorum bellum*, a combat between two persons.

Authorized duels were such whose motive was the good of their country, when one, or a small number of combatants, were chosen to save the blood of a whole army, and decide, by victory or death, the quarrels of kings or whole nations. Thus Goliath and David, the Horatii and Curiatii, and several others.

Duelling was so general a method of determining differences among the nobles, that even ecclesiastics were not excused; only, to prevent their being stained with blood, they procured champions to fight for them. None were excepted from combat, but sick people, cripples, and such as were under twenty-one years of age, or above sixty. Jufts and tournaments, doubtless, rendered duels more frequent.

We have good proof that duelling was authorized before the Normans came into England, though not so frequent and solemn as after the Conquest. These are, however, now known no longer, and we could wish the private practice of duelling was also buried in oblivion.

DUKE is either the title of a sovereign prince, as the duke of Savoy, Parma, &c. the grand duke of Tuscany, Muscovy, &c. or it is the title of honour and nobility next below princes.

DULCIFYING, in pharmacy, is the sweetening, or rendering insipid, any matter impregnated with salts, by washing it in pure water.

The word is formed from the Latin, *dulcis*, sweet, and *facio*, to make.

DULEDGE, in gunnery, a peg of wood which joins the ends of the six fellos that form the round of a wheel of a gun-carriage. The plate of iron on the outside of the wheel, which strengthens the joint, is called the duledge-plate.

DUNG, in agriculture, is of several sorts, as of horses, cows, sheep, hogs, pigeons, geese, hens, &c. All kinds of dung contain some matter, which, when mixed with the soil, ferments therein, and, by that fermentation, dissolves the texture of the earth, and divides and crumbles its particles very much. This is the real use of dung in agriculture;

for, as to the pure earthy part of it, the quantity is so very small, that it bears an extremely inconsiderable proportion to that of the earth it is intended to manure.

DUNGEON, or **DONJON**, in fortification, is commonly a large tower or redoubt of a fortress, whither the garrison may retreat, in case of necessity, and capitulate with greater advantage.

DUNG-MEERS, in husbandry, places where soils and dungs are mixed and digested together: for this purpose it is usual to dig a pit sufficient to hold the stock of soil the husbandman is capable of making; and to prepare it at the bottom with stone and clay, that it may hold water, or the moisture of the dung; and besides, it should be so situated that the sinks and drips of the houses and barns may run into it. Into this pit they cast refuse fodder, litter, dung, weeds, &c. where they lie and rot together, till the farmer have occasion for it.

DUO, or **DUET**, in music, a song or composition to be performed in two parts only; one sung, and the other played on an instrument, or by two voices alone: it is also called a duo, when two voices sing different parts, accompanied with a third, which is a thorough bass. Unisons and octaves must be rarely used in duo's, except at the beginning and end.

DUODENUM, in anatomy, the first of the small intestines, so called because it is about twelve fingers breadth in length. It begins at the right orifice of the stomach, then turns towards the spine, and ends on the left side, where the circulations begin. It is a kind of succedaneous stomach; and performs the like functions, as appears from its internal structure, which is the same with that of the stomach, for the glandulous villose coat, out of which their constantly distils a solvent juice in the stomach, is continued through the duodenum. Besides this glandulous coat, the duodenum is furnished with innumerable small glands, which, upon the separation of the tunica villosa, are very conspicuous in the nervous coat, and which were first discovered by the famous Brunnerus. Besides, it has also some peculiar and remarkable ducts, which discharge into its cavity a highly active menstruum: for the bilious juice runs in a less quantity from the gall bladder, but in a larger from the liver and its biliary ducts. In like manner the duct emerging from the pancreatic gland, which is remarkably large, conveys into it a great quantity of lymph of a solvent nature: and it is farther observable, that these two ducts run together in a human body, and their orifices end in a papilla, and are directly placed over the bottom of the flexure of the duodenum, that the liquids conveyed by these ducts might descend drop by drop on the subjacent mass of chyle. We do not observe any lacteals in the duodenum, and consequently there is no such secretion made there, as in the other intestines, particularly the jejunum; and for

this reason the mesentery does not reach to the duodenum, though all the other small intestines adhere to it. It is very observable, that there is not any animal but what has this flexure of the intestine, or little succedaneous stomach; and that no animal is without the bilious juice, which is generated in the liver, and poured copiously into the duodenum; which manifestly proves, that nature has exerted her utmost skill in fashioning this part of the body, so necessary for the preservation of the life and health of animals.

DUPLE Ratio, in mathematics, is when any number or quantity is contained in another twice; as 6 is in a duple ratio to 3.

Sub-DUPLE Ratio, in mathematics, is when any number or quantity is contained in another twice; thus 3 is said to be sub-duple to 6.

DUPLICATE Ratio, is a ratio compounded of two ratios; as the duplicate ratio of a to b is the ratio of $a a$ to $b b$, or the square of a to the square of b .

In a series of geometrical proportionals, the first term to the third is said to be a duplicate ratio of the first to the second: Thus, in 2, 4, 8, 16, the ratio of 2 to 8 is duplicate to that of 2 to 4; so that duplicate ratio is the proportion of square, as triplicate is of cubes, &c. and the ratio of 2 to 8 is said to be compounded of that of 2 to 4, and of 4 to 8.

DUPPLICATION is the doubling of any thing, or multiplying of it by 2: it is also the folding of any thing back again on itself.

DUPPLICATION of the Cube, is to find the side of a cube that shall be double in solidity to a given cube, which is a famous problem cultivated by the geometers these two thousand years.

It was first proposed by the oracle of Apollo at Delphos; which, being consulted about the manner of stopping a plague then raging at Athens, returned for answer, that the plague should cease when Apollo's altar, which was cubical, should be doubled. Upon this, they applied themselves, in good earnest, to seek the duplication of the cube, which hence-forward was called the Delian problem.

The solution of this problem depends upon finding two mean proportionals between two given lines: for if the side of a given cube be $= a$, and the side of a double cube be $= y$, then will $2a^3 = y^3$; or putting $b = 2a$, it will be $aab = y^3$; therefore it will be $a a : y y :: y : b$; or, making $z = \frac{y y}{a}$,

it will be $a : z :: y : b$; so that these four quantities will be continual proportionals: consequently y , the side of the cube sought, is the second of two mean proportionals between a and b .

DUPPLICATION, among anatomists, is the doubling of any membranes, when they run off to some distance, and return again.

DUPONDIOUS, in antiquity, the weight of two pounds;

DYE

pounds; also a piece of money equal to two as's in value.

The word is derived from the Latin, *duo*, two, and *pondo*, a pound weight.

DURA MATER, in anatomy, one of the membranes, or meninges, as they are called, which surround the brain. See the article *Dura MATER*.

DURATION, an idea which we get by attending to the fleeting and perpetually perishing part of succession; the idea of succession being acquired by reflecting on that train of ideas which constantly follow one another in our minds, as long as we are awake. The simple modes of duration are any different lengths of it whereof we have distinct ideas; as hours, days, years, time, eternity, &c.

DURATION, as marked by certain periods and measures, is what we most properly call time. See the article *TIME*.

DURATION of Action, according to Aristotle, is confined to a natural day in tragedy; but the epopea, confined to the same critic, has no fixed time.

DUTCHY, in geography, an appellation given to the dominions of a duke. See the article *DUKE*.

DUTCHY-COURT, a court of the dutchy-chamber of Lancaster, held at Westminster, before the chancellor of the same, for matters concerning the lands and franchises of that dutchy.

DUTY, in general, denotes any thing that one is obliged to perform.

DUTY, in polity and commerce, signifies the impost laid on merchandizes, at importation or exportation, commonly called the duties of customs; also the taxes of excise, stamp-duties, &c.

DUTY, in the military art, is the exercise of those functions that belong to a soldier.

DUUMVIRATE, the office or dignity of the duumviri.

The duumvirate lasted till the year of Rome 388, when it was changed into decemvirate.

DWAL, in heraldry, the herb night-shade, used by such as blazon with flowers and herbs, instead of metals and colours, for sable or black.

DYE, in architecture, any square body, as the trunk, or notched part of a pedestal, or it is the middle of the pedestal, or that part included between the base and the cornice, so called because it is often made in the form of a cube or dye.

DYEING, the art of giving a lasting colour to silks, cloths, and other substances, whereby their beauty is much improved, and value enhanced.

The art of dyeing may be divided into as many branches as there are different colours to be communicated, and sorts of different stuffs to be subjects of it.

DYEING of cloths, serges, druggets, and other woollen manufactures. For black, in cloths and stuffs of price, it is begun with a strong decoction of woad and indigo, which give a deep blue;

DYE

after which, the stuffs, being boiled with alum and tartar, or pot-ashes, are to be maddered with common madder; then dyed black with Aleppo galls, copperas, and fumac; and finished by back boiling in weld. Scarlet is dyed with kermes and cochineal, with which may also be used agaric and arsenic. Crimson-scarlet is given with cochineal-mestich, aqua fortis, sal armoniac, sublimate, and spirit of wine. Violet, scarlet, purple, amaranth, and pansy-scarlet, are given with woad, cochineal, indigo, braziletto, brazil, and orchal. For common red, pure madder is used, without other ingredients. Crimson-reds, carnations, flame, and peach-colours, are dyed, according to their several hues, with cochineal-mestich, without madder, or the like. Crimson-red is prepared with Roman alum, and finished with cochineal. Peach-colour must be back boiled a little with galls and copperas, or the like. Orange aurora or golden yellow, brick-colour, and onion-peel colour, are given with woad and madder, tempered according to their respective shades. For blues, the dark are given with strong tincture of woad: the brighter with the same liquor, as it weakens in working. Dark browns, minims, and tan-colours, are given with woad, weaker in decoction than for black, with alum and pot-ashes; after which, they are maddered higher than black: for tan-colours, a little cochineal is added. Pearl-colours are given with galls and copperas; some are begun with walnut-tree roots, and finished with the former; though, to make them more serviceable, they dip them in a weak tincture of cochineal. Greens are begun with woad, and finished with weld. Pale-yellows, lemon-colours, and sulphur-colours, are given with weld only. Olive-colours of all degrees are first put in green, and taken down again with soot, more or less, according to the shade required. Teulemont, hair colour, musk, and cinnamon-colour, are given with weld and madder. Nacarar, or bright orange-red, is given with weld and goats-hair, boiled with pot-ashes. Eustie here is forbid, as a false colour.

DYEING of Wools for Tapestry is performed after the same manner as cloths, excepting blacks, which are only to be woaded, and then put in black as above.

Black wools for cloths and serges may be begun with walnut-tree root, and walnut rinds, and finished by dipping in a vat of black.

DYEING of Silks is begun by boiling them with sope, &c. then scowering and washing them out in the river, and steeping them in alum-water cold. For crimson they scour them a second time before putting them in the cochineal vat.

Red-crimson is dyed with pure cochineal-mestich, adding galls, turmeric, arsenic, and tartar, all put together in a copper of fair water almost boiling: with these the silk is to be boiled an hour and an half; after which, it is suffered to stand in the liquor till

DYE

next day. Violet-crimson is also given with pure cochineal, arsenic, tartar, and galls; but the galls in less proportion than in the former: when taken out, it is to be well washed, and put in a vat of indigo. Cinnamon-crimson is begun like the violet, but finished by back-boiling, if too bright, with copperas; if dark, with a dip in indigo. Light-blues are given in a vat of indigo. Sky-blues are begun with orchal, and finished with indigo: for citron-colours, the silk is first alumed, then welded, with a little indigo. Pale yellows, after aluming, are dyed in weld alone. Pale and brown auroras, after aluming, are welded strongly, then taken down with rocou dissolved with pot-ashes. Flame-colour is begun with rocou, then alumed, and dipped in a vat or two of brazil. Carnation, and rose-colours, are first alumed, then dipped in brazil. Cinnamon-colour, after aluming, is dipped in brazil and brazilletto. Lead-colour is given with fustic, or with weld, brazilletto, galls, and copperas. But the galls, on these and other occasions, are not to be used, because they increase the weight to the damage of the purchaser; for which reason, it is punished in France as a fraud: in reality, few but black silks need galls.

Black silks, of the coarser sorts, are begun with scouring them with soap, as for other colours; which done, they are washed out, wrung, and boiled an hour in old galls, where they are left to stand a day or two; after which they are washed again with fair water, wrung, and put in another vat of new and fine galls; then washed and wrung again, and finished in a vat of black. Fine black silks are only put once into galls, viz. the new and fine sort, which has only boiled an hour; then they are washed, and wrung out, and dipped thrice in black, to be afterwards brought down by back boiling with soap.

DYEING of Thread is begun with scouring it in lye of good ashes; after which it is wrung, rinsed out in river water, and wrung again. For a bright blue, it is given with brazilletto and indigo. Bright green is first dyed blue, then back-boiled with brazilletto and verdeter, and lastly woaded. For a dark green, it is given like the former, only darkened more before woaded. Lemon, or pale yellow, is given with weld, mixed with rocou. Orange and isabella, with fustic, weld, and rocou. Red, both bright and dark, with flame colour, &c. are given with brazil, either alone, or with a mixture of rocou. Violet, dry rose, and amaranth, are given with brazil, taken down with indigo. Feulemort, and olive-colour, are given with galls and copperas, taken down with weld, rocou, or fustic. Black is given with galls and copperas, taken down and finished with brazilletto wood.

DYEING of Hats is done with brazilletto, galls, copperas, verdigrise, dissolved and boiled in a copper, capable of receiving, besides the liquor, twelve

DYE

dozen of hats on their blocks, or moulds. Here the hats are suffered to boil some time; after which they are taken out, and suffered to stand and cool; then dipped in again; and thus alternately, oftener or seldomer, as the stuff is of a nature to take the dye with more or less difficulty.

Proof of DYES.—There are divers ways of proving the truth of dyes, or examining the justness and legitimacy of their composition. To discover whether a cloth has been duly treated by the dyer, and the proper foundation laid, a white spot, by the French called *rosette*, of the bigness of a shilling, ought to be left; besides a white stripe between the cloth and the list.

Farther proof is had by boiling the dyed stuff in water, with other ingredients, different according to the quality of the dye to be proved. If the colour sustain the test, i. e. do not discharge at all, or very little, so that the water is not tinged by it, the dye is pronounced good: otherwise, false.

DYEING of Leather, Skins, &c.—Blue is given by steeping the subject a day in urine and indigo, then boiling it with alum: or it may be given by tempering the indigo with red wine, and washing the skins therewith. Red is given by washing the skins, and laying them two hours in galls, then wringing them out, dipping them in a liquor made with lignustrum, alum, and verdigrise in water; and lastly, in a dye made of brazil wood, boiled with lye. Purple is given by wetting the skins with a solution of roche alum in warm water, and, when dry again, rubbing them with the hand with a decoction of log-wood in colder. Green is given by smearing the skin with sap-green and alum-water boiled: to darken the colour, a little more indigo may be added. Dark-green is also given with steel filings and sal armoniac steeped in urine till soft, then smeared over the skin; which is to be dried in the shade. Sky-colour is given with indigo steeped in boiling water; and the next morning warmed and smeared over the skin. Yellow, by smearing the skin over with aloes and linseed-oil dissolved and strained: or by infusing it in weld. Orange-colour is given by smearing with fustic-berries boiled in alum water: or, for a deep orange, with turmeric.

DYEING, or STAINING, of Wood for inlaying, veneering, &c.—Red is done by boiling the wood in water and alum; then taking it out, adding brazil to the liquor, and giving the wood another boil in it. Black, by brushing it over with log-wood boiled in vinegar, hot: then washing it over with a decoction of galls and copperas, till it be of the hue required. Any other colour may be given by squeezing out the moisture of horse-dung through a sieve, mixing it with dissolved roche alum and gum arabic; and to the whole adding green, blue, or any other colour designed: after standing two or three days, pear-tree, or other wood, cut to the thickness

DYE

hies of half-a-crown, is put into the liquor boiling hot, and suffered to remain till it be sufficiently coloured.

DYEING of Bone, Horn, or Ivory—Black is performed by steeping brals in aqua-fortis till it be returned green: with this the bone, &c. is to be washed once or twice; then put in a warmed decoction of log-wood and water. Green is begun by boiling the bone, &c. in alum-water; then with verdigrise, sal ammoniac, and white-wine vinegar; keeping it hot therein till sufficiently green. Red is begun by boiling it in alum-water, and finished by decoction in a liquid compounded of quick-lime steeped in rain-water, strained, and to every pint an ounce of brazil-wood added. In this decoction the bone, &c. is to be boiled till sufficiently red.

DYEING, or STAINING, Horn to imitate Tortoise-Shell.—The horn to be dyed must be first pressed into proper plates, scales, or other flat form; and the following mixture prepared.

“Take of quick-lime two parts, and of litharge one part; temper them together to the consistence of a soft paste with soap-lye.” Put this paste over all the parts of the horn, except such as are proper to be left transparent, in order to give it a nearer resemblance of the tortoise-shell. The horn must remain in this manner covered with the paste till it be thoroughly dry; when the paste being brushed off, the horn will be found partly opaque and partly transparent, in the manner of tortoise-shell; and when put over a foil, of the kind of latten, called assidue, will be scarcely distinguishable from it. It requires some degree of fancy and judgment to dispose of the paste in such a manner as to form a variety of transparent parts, of different magnitudes and figures, to look like the effect of nature; and it will be an improvement to add semi-transparent parts: which may be done by the mixing whitening with some of the paste to weaken its operation in particular places; by which spots of a reddish brown will be produced, which, if properly interperfed, especially on the edges of the dark parts, will greatly increase both the beauty of the work, and its similitude with the real tortoise-shell.

DYEING, or STAINING, Paper or Parchment yellow—Paper may be stained yellow by the tincture of French berries, prepared by boiling them in water with a little alum: but a much more beautiful yellow may be obtained by using the tincture of turmeric, formed by infusing an ounce or more of the root, powdered, in a pint of spirit of wine. This may be made to give any teint of yellow, from the lightest straw to the full colour called French yellow; and will equal in brightness the best dyed silks. If yellow be wanted of a warmer or redder cast, annatto, or dragon's-blood, must be added to the tincture.

The best method of using these, and the follow-

DYS

ing tinctures, is to spread them even on the paper or parchment by means of a broad brush in the manner used in varnishing.

DYEING, or STAINING, Paper, or Parchment, red.—Paper or parchment may be stained red with the common red ink. It may be stained of a scarlet hue by tincture of dragon's-blood in spirit of wine; but this will not be bright.

A very fine crimson stain may be given to paper, by a tincture of the Indian lake; which may be made by infusing the lake some days in spirit of wine; and then pouring off the tincture from the dregs.

DYEING, or STAINING, Paper, or Parchment, green.—Paper, or parchment, may be stained green by a solution of verdigrise in vinegar; or by the crystals of verdigrise dissolved in water. As also by the solution of copper in the aqua-fortis, made by adding filings of copper gradually to the aqua-fortis, till no ebullition ensues; or spirit of salt may be used in the place of aqua-fortis.

DYEING, or STAINING, Paper, or Parchment, blue.—A blue colour may be given to paper or parchment by staining it green by any of the above methods, and then brushing it over with a solution of pearl-ashes. It may also be done by a solution of indigo procured at the dyers.

DYEING, or STAINING, Paper, or Parchment, orange.—Stain the paper or parchment of a full yellow, by means of the tincture of turmeric as above directed; then brush it over with a solution of fixed alkaline salt, made by dissolving half an ounce of pearl-ashes, or salt of tartar, in a quart of water, and filtering the solution.

DYEING, or STAINING, Paper, or Parchment, purple.—Paper or parchment may be stained purple by orchal; or by a tincture of log-wood. The juice of ripe privet-berries, expressed, will also give a purple dye to paper or parchment.

DYKE, or DIKE. See the article **DIKE**.

DYNASTY, among ancient historians, signifies a race or succession of kings of the same line or family: such were the dynasties of Egypt.

DYSCRACY, among physicians, denotes an ill habit or state of the humours, as in the scurvy, jaundice, &c.

DYSENTERY, in medicine, an exulceration of the intestines, attended in the beginning with an excretion of a biting, bilious humour, afterwards with abrasions of the intestines, and, at last, blood in moderate quantities is voided.

The word is derived from the Greek, *dys*, importing difficulty, and *εντερων*, the intestines.

When this disease is attended with a bloody flux and severe gripes, the intestines are commonly ulcerated, and discharge blood; which comes away, sometimes with liquid excrements, sometimes with slime accompanied with fleshy particles. The patient is seized with frequent irritations to stool, and a pain of the

D Y S

D Y T

anus; he discharges but little at a time, and his pain is increased by every stool; and as this disease arises from an inflammation, there is always some degree of fever with it.

Wherefore, to come to a cure, the first thing to be done is to draw blood: then a vomit to be given, for which ipecacuanha wine is very proper, and to be repeated two or three times every third or fourth day.

During this course, and afterward, medicines proper for stopping the flux and healing the ulcerated membranes are to be administered: and of this sort I know none better than the following bolus, composed of the cordial confection and French bole, each one scruple; Thebaic extract, one grain, given three times a day.

And it will be of service to inject clysters, either of fat broth, with the addition of Venice-treacle or electuary of scordium, or of the white decoction and starch; or, in place of this last, of the chalk julep, with two or three grains of the Thebaic extract, when occasion requires it. Lastly, I recommend an useful remark, that this course is sometimes rendered ineffectual by a bad habit of body. In such cases, to the foregoing method it will be proper to add medicines which correct the humours; and indeed some doses of the rhubarb, with a small proportion of dulcified mercury sublimate, commonly called calomel, will prove very conducive to that end.

Besides these diseases, a vomica, or internal supuration, is sometimes formed in the stomach. This indeed seldom happens, but yet I have observed it more than once, when the patient vomited up a mixture of blood and purulent matter in large quantities.

The case is terrifying indeed; but yet, generally speaking, it is not attended with any greater danger; and it is cured by medicines which heal the ulcerated

membranes, especially Locatelli's balsam. *Mead's Monita et Præcepta.*

DYSOREXY, among physicians, denotes a want of appetite, proceeding from a weakly stomach. See APPETITE.

DYSEPSY, in phyc, a difficulty of digestion; or rather a depraved digestion, when the aliments in the stomach, for want of a due strength in the digestive organs, follow their spontaneous tendency, and contract an alkaline or acid putrefaction.

The word is formed from the Greek, *dys*, importing difficult, or bad, and *pepsis*, to correct.

DYSPNOEA, in phyc, a difficulty of breathing.

The word is derived from the Greek, *dys*, difficulty, and *pneus*, to breathe.

A difficulty of breathing may be caused by any thing that can affect any part of the thorax, particularly the heart, large arteries, and lungs, by crude tubercles, vomica's, polypuses, and several other disorders.

DYSURIA, in medicine, a difficulty of making urine, attended with a sensation of heat and pain.

The word is derived from the Greek, *dys*, importing painful, and *urine*.

This disease is distinguished from a stranguy, as, in the latter, the urine is voided by only a drop, as it were, at a time, but, however, with pain; and from an ichury, as in this disorder, there is an almost total suppression of urine.

DYTISCUS, water-beetle, in zoology, a genus of insects of the order of the coleoptera, the antennæ of which are slender and setaceous, and their feet formed for swimming. See COLEOPTERA.

Authors enumerate a great many species of this animal, among which is the great water-beetle, the largest of all European beetles, being an inch and an half in length, and all over of a deep and somewhat glossy black.

E.

E A G

E The second vowel, and fifth letter of the alphabet. The letter E is most evidently derived from the old character **I** in the ancient Hebrew and Phœnician alphabets, inverted by the Greeks to this position E, and not from the Hebrew He **ה**. From the same origin is also derived the Saxon *e*, which is the first letter in their alphabet that differs from the Latin one. It is formed by a narrower opening of the larynx than the letter A; but the other parts of the mouth are used nearly in the same manner as in that letter.

It has a long and short sound in most languages: the short sound is audible in *bed, fret, den*, and other words ending in consonants: its long sound is produced by a final *e*, or an *e* at the end of words, as in *glebe, here, hire, scene, sphere, interfere, revere, sincere*, &c. in most of which it sounds like *ee*; as also in some others by coming after *i*, as in *believe, chief, grief, relieve*, &c. and sometimes this long sound is expressed by double *ee*, as in *bleed, beer, creed*, &c. Sometimes the final *e* is silent, and only serves to lengthen the sound of the preceding vowel, as in *rag, rage, flag, stage, hug, huge*, &c. The sound of *e* is obscure in the following words, *oven, heaven, bounden, fire, aire, massacre, maugre*, &c.

The Greeks have their long and short *e*, which they call Epsilon and Eta. The French have at least six kinds of *e*'s: the Latins have also a long and short *e*; they also write *e* instead of *a*, as *dicem* for *dicam*. *E* and this is, no doubt, the reason why *a* is so often changed into *e*, in the præter tense, as *ago, egi; facio, feci*, &c. *E* was also a numeral letter standing for 250, according to the verse,

E quoque ducentos et quinquaginta tenebit.

EAGLE, *Aquila*, in ornithology, the English name of several species of the falcon kind. See the article **FALCON**.

In heraldry, the eagle is accounted one of the most noble bearings in armoury, and according to the learned in this science, ought to be given to none but such as greatly excel in the virtues of generosity and courage, or for having done singular services to their sovereigns; in which cases they may be allowed a whole eagle, or an eagle naissant, or only the head or other parts thereof, as may be most agreeable to their exploits.

E A R

EAGLE, *Aquila*, in astronomy. See **AQUILA**.
EAGLE, in architecture, a figure of that bird anciently used as an attribute of Jupiter, in the capitals and friezes of the columns of the temples consecrated to that god.

EAGLE-STONE, *Ætites*, in natural history. See the article **ÆTITES**.

Black EAGLE, an order of knighthood, instituted by the elector of Brandenburg, in 1701, on his being crowned king of Prussia.

The knights of this order wear an orange coloured ribbon, suspending a black eagle.

White EAGLE, a like order in Poland, instituted in 1325, by Uladislaus V. on occasion of the marriage of his son Casimir to the daughter of the great duke of Lithuania.

The knights of this order wear a chain of gold, suspending a silver eagle, crowned.

White EAGLE is also a term used by chemists for *mercurius dulcis*.

EAGLET, a diminutive of eagle, properly signifying a young eagle. In heraldry, when there are several eagles on the same escutcheon, they are termed *eaglets*.

EALDERMAN, or **EALDORMAN**, the same with *alderman*. See **ALDERMAN**.

EAR, *Auris*, in anatomy, the organ of hearing.

Anatomists generally distinguish the ear into external and internal; the greatest part of the external ear consists of a large cartilage, which is the basis of all the other parts. There are two portions, the one large and solid, called *pinna*, which is the superior part; the other small and soft, called the *lobe*, which makes the lower part. We may likewise consider two sides in the outward ear, one turned obliquely forward, and irregularly concave; the other turned obliquely backward, and unequally convex; the forehead is divided into four eminences and as many cavities; the first eminence is in the helix, which is the large folded border, or circumference of the great portion of the ear: the second is the *anthelix*, which is the large oblong eminence surrounded by the helix: the third is the *tragus*, which is the smaller anterior protuberance below the anterior extremity of the helix: the fourth is the *antitragus*, which is the posterior tubercle below the inferior extremity of the *anthelix*.

The

The first cavity is the hollow of the helix; the second is the depression at the superior extremity of the anhelix, called *fossa navicularis*; the third is the concha, or great double cavity, that lies under the anhelix, the upper bottom of which is divided from the lower by a continuation of the helix, like a transverse crista; and, lastly, the meatus of the external ear at the bottom of the concha.

The backside of the ear has only one considerable eminence, which is a portion of the convex side of the concha, the other portion being hid by the adhesion of the ear to the *os temporis*.

The external ear is fixed to the cranium by muscles, or rather ligaments. The skin is a continuation of that which covers the neighbouring parts of the temporal region. The arteries of the external ear come anteriorly from the *arteria temporalis*, and posteriorly from the *occipitalis*. The veins are branches of the *jugularis externa*. The *portio dura* of the auditory nerve gives off a branch which runs up behind the ear, to the backside of which it sends several filaments; and the trunk of the branch sends likewise filaments to the meatus and forefide of the ear. The second vertebral pair sends also a branch to the ear, the ramifications of which communicate with those of the other.

The internal ear consists chiefly of several bony pieces, which may be divided into four general parts; the external meatus auditorius; the tympanum, or barrel of the ear; the labyrinth; and the internal meatus auditorius; or it may be divided into immoveable or containing parts, which take in all the four already mentioned; and moveable or contained parts, which are four little bones lodged in the tympanum, called *incus*, *malleus*, *stapes*, and *os orbiculare*, or *lenticulare*.

The external auditory passage is about half an inch in length, running obliquely from behind forward: its cavity is almost oval, wider at the entry than at the middle, after which it widens again by degrees: it terminates inwardly by an even circular edge, the upper part being outward, and the lower part inward. The concave side of this edge is grooved quite round.

The tympanum is an irregularly hemispherical cavity, the bottom of it being turned inward, and the mouth joined to the circular groove. It has three remarkable eminences; the first is a large tuberosity lying in the very bottom of the barrel; a small irregular pyramid situated about the tuberosity, the apex of which is perforated, and on one side of the basis two small bony filaments are often found parallel. In the third eminence is a cavity shaped like the mouth of a spoon, situated a little towards the anterior part of the bottom of the barrel; and at a very small distance from its point is a little bony ridge. The principal cavities in the tympanum are the opening of the *maïstoid cells*, the opening of the *Eustachian tube*, the bony half-canal, the fenestra

ovalis and *rotunda*, and the small hole in the pyramid.

The *incus* or anvil may be divided into body and branches; the body is a large substance turned forward; the branches are two; one long turned downward, the other short turned backward. The *malleus* is a long bone with a large head, a small neck, and two apophyses, one in the neck, the other in the handle. The *stapes* is a small bone, so denominated from its resemblance to a stirrup; it is divided into the head, legs, and basis. The *orbicular* or *lenticular* bone lies between the head of the *stapes* and extremity of the long leg of the *incus*, being articulated with each of these.

The labyrinth is divided into three parts; the anterior, called *cochlea*; the middle, termed *vestibulum*; and the posterior; the labyrinth, in particular, comprehends the three semi-circular canals: the *cochlea* is a sort of spiral shell, with two ducts, formed in the anterior part of the apophysis *petrosa*, like the shell of a snail. The parts to be distinguished in it are the basis, the apex, the spiral lamina, or half-septum, by which its cavity is divided into two half-canals, the spindle round which the *cochlea* turns, and lastly, the orifice and union of the two ducts. The *vestibulum* is an irregularly round cavity, less than the tympanum, and situated more inward, and a little more forward. The semi-circular canals are three in number; one vertical and superior; one vertical and posterior; and one horizontal.

The internal auditory hole is the backside of the apophysis *petrosa*, in some measure behind the *vestibulum* and basis of the *cochlea*. It is a kind of blind hole, divided into two fossulae; one large, the other small. The large one lies lowest, and serves for the *portio mollis* of the auditory nerve: the small one is uppermost, and is the opening of a small duct, through which the *portio dura* of the same nerve passes. To this latter duct *Fallopian* gave the name of *aqueduct*.

The other parts of the ear are principally the *membrana tympani*, the *periosteum* of the barrel, the *membrana maïstoidæ interna*, the muscles of the ossicula, the parts which complete the formation of the *Eustachian tube*, the arteries, veins, and nerves.

To begin with the *Eustachian tube*, otherwise called *ductus auris palatinus*, and in France generally the *aqueduct*, which is not to be confounded with the *aquæductus Fallopii*: this duct reaches from the cavity of the barrel to the root of the internal ala of the apophysis *pterygoïdes*; it is made up of two portions, one entirely bony, and the other partly bony, partly cartilaginous, and partly membranous. The *Eustachian tube* is furnished with three muscles, according to *Valsalva*; the *pterygo-staphylinus*, the *spheonopterygopalatinus*, and the *palatofalpingæus*, since called by some, *musculus tubæ novus Valsalvæ*; its use is to dilate and keep open

open this channel, as Valsalva first has most ingeniously observed.

The membrana tympani is a thin, transparent, flatish pellicle, whose edge is round, and strongly fixed in the orbicular tube. The periostrum of the tympanum produces that of the small bones; it is likewise continued over the two fenestræ, and enters the Eustachian tube. The cellulæ mastoidæ are very irregular cavities in the substance of the mastoid apophysis, which communicate with each other, and have a common opening towards the inside, and a little above the posterior edge of the orbicular groove.

The ligaments of the ossicula come next in order: the incus is tied by a strong short ligament fixed in the point of the short branch to the edge of the mastoid opening. Between the incus and malleus we find a small short cartilage. The malleus is connected through the whole length of its handle, to the inside of the membrana tympani. The malleus has three muscles; one external, attributed to Caserius, and mentioned by Fabricius ab Aquapendente, is a thin fasciculus of fleshy fibres, lying along the upper-part of the meatus auditorius, between the periostrum and other integuments. The second muscle of the malleus is the anterior, called by Du Verney the external; it is fleshy, long, and thin. It adheres very closely throughout to the Eustachian tube; it is partly accompanied by a nerve which forms what is called the chorda tympani.

The third muscle of the malleus is internal; it is very fleshy and distinct, lying partly on the cartilaginous, and partly on the bony portion of the Eustachian tube, and fixed by one extremity in the apophysis petrosa; afterwards it runs along the cavity of the bony half-canal of the tympanum, where it is invested by a portion of the membranous or ligamentary vagina. The muscle of the stapes is short and thick, and lies concealed within the small bony pyramid at the bottom of the tympanum. The three parts of the labyrinth are lined by a fine periostrum, which is continued over all the sides of their cavities, and shuts the two fenestræ of their tympanum. Through the whole extent of the periostrum of the internal ear, especially the ossicula, semi-circular canals, and half-canal of the cochlea, we discover a vast number of blood vessels. The arteries come partly from the internal carotid, and partly from the arteria basilaris, the small capillary ramifications of which may be observed to accompany the auditory nerve through the internal foramen auditorium. *Winflow.*

EAR, among gardeners, a name given to the leaves that first appear from the seed, which differ considerably from other leaves.

EAR-WIG, *forficula*, in zoology. See the article FORFICULA.

EARL, a British title of nobility, next below a

marquis, and above a viscount. Earls were anciently called comites, because they were wont *comitari regem*, to wait upon the king for counsel and advice.

EARL *Marshal of England*, is a great officer who had anciently several courts under his jurisdiction, as the court of chivalry, and the court of honour. Under him is also the herald's office or college of arms. He hath some pre-eminence in the court of Marthalea, where he may sit in judgment against those who offend within the verge of the king's court. This office is of great antiquity in England, and anciently of greater power than now; and has been for several ages hereditary in the most noble family of Howard.

EARTH, in geography, this terraqueous globe whereon we live, consisting of land and water.

That the earth is nearly spherical may be shewn by the following observations. 1. When we are at sea on board a ship, we may be out of sight of land, when the land is near enough to be visible, if it were not hid from our eye by the convexity of the water; thus let ABCD (Plate XLI. *fig.* 8.) represent part of the globe of the earth; let M be the top of a mountain; this cannot be seen by a person on board a ship at B, because a line drawn from M to his eye at E is intercepted by the convexity of the water: but let the ship come to C, and then the mountain will be visible, because a line may be drawn from M to his eye at F. 2. The higher the eye is, the farther will the view be extended: it is very common for sailors from the top of the mast of a ship to discover land or ships at a greater distance than they can do when they stand upon deck: thus (*fig.* 9.) the top of the tower D may be seen from B, the top of the mast, when it cannot be seen from A, by reason of its being hid by the convexity of the water. 3. When we stand upon the shore, the highest part of a ship is visible at the greatest distance: if a ship is going from us out to sea, we shall continue to see the mast, after the hull or body of the ship disappears, and the top of the mast will continue to be seen longest; if a ship be coming towards us, the top of the mast comes first into view, and we see more and more of it, till at last the hull appears: thus let the eye be at C, when a ship is as far off as at F, only the top of the mast is visible, the hull is hid behind the water; when the ship is nearer, as at E, the hull may also then be seen. If the surface of the sea were a flat, (*fig.* 10.) a line might be drawn from any object situated upon it, as the ship D, to the eye, whether placed high or low, at A or B: in this case, any object upon the earth or sea would be visible at any distance which was not so great as to make the appearance of it too faint, or the angle under which it appears too small, to be seen by us: an object would be visible at the same distance, whether the eye were high or low: not the highest

but the largest objects would be visible to the greatest distance, so that we should be able to see the hull of a ship further off than the mast: all which is contrary to experience. 4. The convexity of the water may be seen upon any still water, as upon a river which is extended in a straight line, a mile or two in length; a little boat upon the water may be seen, at a mile distance, by a man whose eye is any height above the water: but if he stoops down and lays his eye near the water, he will find the surface thereof rising up in such a manner as to cover the boat, and intercept his view of it. 5. Several navigators have sailed quite round the globe; not in an exact circle, for this the winding of the shores, the land running out in many places into the sea, would not admit of; but going in and out, as the shores happen to lie, they have held on the same course, and come home on a different side from that they first set out from: thus, Ferdinand Magellan, setting out on the west-side of Spain, continued sailing westward till he returned home on the east-side of Spain; our Sir Francis Drake, Capt. Dampier, Lord Anson, and others, have done the like; the course they have some of them run is marked upon several maps and globes: these proofs are sufficient to evince the roundness of the water. That the earth is also round is evident, if we consider that the ocean is diffused all over the globe, so as to divide the earth, as it were, into large islands; and that the surface of the earth is not very much higher than the sea, is evident, from the course of rivers, which at a moderate estimate are computed to have not above one mile fall in running a thousand miles, and have their shores much of the same height; as also from the height of mountains, which are none of them found to be above three or four miles higher than the surface of the sea: these experiments prove the earth and sea to have a convex surface every-where. 6. All the appearances of the heaven, both at land and sea, were the same as they would be if the earth were a globe, which proves it to be of that shape; and lastly, in eclipses of the moon, which are caused by the shadow of the earth falling upon the moon, as will appear under the article ECLIPSE. This shadow is always circular, whatever situation the earth is in at that time: now a body can be no other than a globe, which, in all situations, casts a circular shadow: it is true the surface of the earth is not an exact geometrical globe, because it sinks into vallies in some places, and rises into mountains in others; but these inequalities upon its surface are as inconsiderable, when compared with the magnitude of the earth, as the little asperities upon the rind of an orange are to the bulk of the orange; and accordingly we find that mountains and vallies upon the surface of the earth cause no irregularities in its shadow in a lunar eclipse, but the circumference thereof are even and regular, as if it were call by a body exactly globular: the diameter of the earth is about 8000

English miles; the highest mountain is not four miles higher than the surface of the sea, which is about a 2000th part of the earth's diameter: thus it appears that the highest mountain bears no greater proportion to the bulk of the earth than a grain of dust does to a common globe.

But, though the earth be spherical, yet it is not a true sphere, but an oblate spheroid, flattened towards the poles; that is, the axis of the earth is not so long as the diameter of the equator. This was discovered by the following accident:

In 1672; M. Richer, going to Cayenne, in order to make astronomical observations, found, that his pendulum clock, which at Paris had been regulated to the mean motion of the sun, when carried to this island, which is about five degrees distant from the equator, lost every day two minutes and twenty-eight seconds. At his return he reported this experiment, and, as it seemed to be of some importance, it immediately engaged the attention of the greatest mathematicians.

But they presently perceived that the slowness of the pendulum must proceed from a diminution of the pressure of gravity; and, consequently, that the pressure of gravity was less at Cayenne than at Paris: for, when a pendulum of a clock departs in its motion from its perpendicular, the forces which causes it to return is gravity; whence it follows, that the greater the degree of gravity is, the quicker its motion will be, and *vice versa*: and, as the motion of the pendulum was slower at Cayenne than at Paris, the pressure of gravity must be less. Indeed, in warm climates all rods of metal will lengthen, whence the rod of the pendulum must be somewhat longer at Cayenne than at Paris; and, consequently, its oscillations slower. But as we know in what proportion heat will lengthen pendulums, and, consequently, how much it retards their motion, we are satisfied that the heats at Cayenne are not sufficient to solve this phenomenon; but it must, in general, flow from a diminution in the pressure of gravity.

But from whence could proceed the cause of this diminution of gravity? Undoubtedly from this: every body, or particle of matter, that describes a circle round a center, makes a continual effort to recede from the center. It is this force that strains a sling with a stone in it, while you whirl it round, and were its force strong enough, would even break the sling; this effort is called the centrifugal force; to this all revolving bodies are subject, and if they perform their revolution in the same time, it is proportioned to the greatness of the circle they describe.

Now, since the earth revolves round its own axis in twenty-four hours, all the bodies or particles of matter which compose it will describe circles; and consequently each will, more or less, partake of this centrifugal force, in proportion to the circle it describes.

scribes. And, because the particles under the equator describe the greatest circle, therefore they will have the greatest degree of centrifugal force; and the nearer the poles a particle is situated, the less will be its degree of centrifugal force; because the circle it describes will be smaller. The whole effect of this force tends to make bodies recede from the center of the circles they describe, and a part of it is opposite to that of gravity, whose force everywhere impels bodies towards the center of the earth. This part of the centrifugal force continually increases the nearer you approach to the equator; because under the circle, not only the centrifugal force is directly contrary to that of gravity, but also the circles described by the revolving bodies are there the greatest. The great Sir Isaac Newton and M. Huygens carried their calculations so far as to compare the quantity of the centrifugal force with gravity, and found that under the equator it was $\frac{1}{187}$ part of gravity; that is, a body under the equator lost the 289th part of its weight: then, considering that the waters of the sea are in equilibrio all over the earth, and supposing the earth to be formed of a homogeneous and fluid matter, or that had originally been so, they undertook to determine its figure by the laws of hydrostatics.

That this fluid matter might be at rest, and the waters continue equal on each side, the weight of a column of water, continued from the center to the equator, must of consequence be equal to that of a column of water continued from the center to the pole; for otherwise they would not continue in equilibrio; but, as the matter which formed the column continued from the center to the equator, was rendered lighter by the centrifugal force than that which composed the column which was continued from the center of the pole; it follows that the column at the equator must be longer than at the poles, and consequently the earth is flattened at the poles.

This theory was greatly confirmed by the figure of the planet Jupiter; for as this planet is much greater than the earth, his diameter being 8155 miles, whereas the earth's is only 7964 miles; and as the revolution of this planet about its own axis is performed in 9 hours, 56 minutes, it follows, that the equatorial parts of his surface must have a prodigious velocity, which must consequently cause him to be a spheroidal figure. Accordingly, the ingenious Mr. Pound discovered that the axis of the equator was to that of the poles, as 12 to 13.

Here the question might have rested, and had probably never been accurately solved, had it not been for the opposition it met with from M. Cassini, though he afterwards ingenuously owned his mistake. This gentleman, having measured the meridian of France from Dunkirk to Colliours, in Roussillon, declared, contrary to the opinion of all the mathematicians, that the earth, instead of being flattened,

was lengthened towards the poles; that is, instead of being an oblate, it was a prolate spheroid, higher at the poles by about 95 miles. Sir Isaac Newton remonstrated, that, if this was the figure of the earth, bodies must be lighter, and a pendulum longer at the equator than in France, about half an inch; and that the diameter of the earth's shadow, from south to north, must exceed its diameter from east to west 2 min. 46 sec. a twelfth part of the moon's diameter; all which was manifestly contrary to fact and observation: but even this, from so great a man, could not entirely remove all the scruples of some mathematicians, as they were supported by the observations and experiments of so diligent an artist as M. Cassini.

At length the king of France, at an expence becoming a monarch who delighted in cultivating the sciences, sent two companies of mathematicians, the one to the equator, and the other to the arctic circle, in order to decide this affair, and accurately determine the true figure of the earth.

Were the earth a perfect sphere, all the meridians would be circles; consequently every degree of the meridian, like the degrees of a circle, would be equal; and every line, standing at right angles, with (or upright upon) the meridian, would, if continued inwards, meet at the center. The French king's astronomers, by actually measuring a degree of the meridian, in the south of France, and the same gentlemen measuring a degree of the meridian at the polar circle, found the latter exceeded the former by 86,8 English miles.

This being known, the difference of a degree at the pole from a degree at the equinoctial may be found, by examining *fig. 11.* where, let AB be the equatorial diameter, P p its polar diameter, RSTV a great circle in the sphere of the fixed stars, and let RS be a degree on the meridian at the equinoctial, and TV a degree at the pole, and that all plumb lines are perpendicular to the plane of the horizon, then will the two plumb lines Rr and Ss, if continued, meet at x, and the space or distance rs be the measure of one degree on the earth under the equinoctial: also, if the two plumb lines Tt and Vv be continued, they will not meet till they pass the earth's center, and have their point of concurrence at O. And the distance of vt be the measure of a degree on the earth under the pole. But rs is the 360th part of a circle, whose semi-diameter is rx, the equatorial degree, and tv the polar degree, the 360th part of a circle, whose semi-diameter is the line vo. Therefore, the length of a degree of the meridian, under the equinoctial, has the same ratio to a degree under the pole, as the line rx has to the line vo, which was to be demonstrated.

From whence may be drawn the following corollaries:

1. That if a hole was bored plumb down quite through the earth, it would not pass through the earth's

earth's center, except the place bored was under the pole, or under the equinoctial.

2. If a stone was to be dropped from the center of this hole, it would not fall directly down, but strike against one side. And if it could find a passage according to its natural inclination, by the power of gravity, it would describe a curve of the spiral kind, and would rest at last at the earth's center; but if the diurnal and annual motion of the earth be taken into consideration, the curve will be of another kind.

3. If an observer was at the earth's center, and the earth transparent, such persons as were travelling towards the poles would seem to him to lean forward, like men climbing the outside of an hill, and those travelling towards the equator, to lean backwards like those going down an hill.

4. An observer upon a small island, and under the equinoctial, having a free and open horizon, he would see farther, when he directed his sight east or west, than when it was directed north or south; and that the space contained within the limits of a man's view, is no where circular but just at the poles.

By observations made under the arctic circle, by Mefs^{rs}. de Maupertuis, Clairaut, Camus, Le Monnier, the Abbé Outhier, and M. Celsius of Upsal; the length of a degree in whose middle the pole was elevated $66^{\circ} 31'$ was found to be 57437 toises (a toise is = 6,408 English feet): but by those of Mr. Picard, as corrected by the said gentleman, the length of one near Paris, where the mean latitude was $48^{\circ} 50'$ appears to be only 56925 toises, differing from the former by 512 toises. Now, to determine the earth's true dimensions by the foregoing theorems applied to these observations, let $S = \text{Nat. sine of } 66^{\circ} 33' s = \text{that of } 48^{\circ} 50' D = 57437$, $d = 56925$, and $E = e = 1$; then $r = \frac{D-d}{d} = m = .009 \frac{c}{b} \left(= 1 - \frac{m}{3 \times 88 - 11} \right) = .0982$, $b = 3272300$, $c = 3236500$, and $b - c = 35800$ toises; wherefore it appears, that the length of the earth's axis, from pole to pole, is 6473000 toises, or 7863,2 English miles; and that the difference between it and the equatorial diameter is about $\frac{1}{82}$ part of the former, or 86,8 miles.

Motion of the EARTH. The earth has a triple motion. 1. A diurnal motion round its own axis, from west to east, in twenty-four hours, which occasions the perpetual succession of days and nights. It is agreeable to reason that the earth should revolve about its axis to account for the appearance of such a vast number of stars which seem to perform their revolutions round the earth in twenty-four hours; for the motion of these stars, were it real, would be incredibly swift and beyond all imagination, because their distance, in respect of us, is almost infinite, and the orbit they have to run round so prodigiously great, that they must move at least 100,000 miles in a

minute.—2. An annual motion round the sun in a year, which produces the different seasons, and the lengthening and shortening of days. Let A, B, C, D, (fig. 12.) represent the orb of the earth, in which it revolves annually round the sun E. A and C are the places of the earth at spring and autumn, B its place at summer, and D at winter. a is the north pole, b the south, cc the polar circle, ddl the parallel of London, ee the tropick of Cancer, ff the equinoctial, gg the ecliptick, gg the tropick of Capricorn, bb the antarctic circle. Now when the earth is at A, that is, in the vernal equinox, the sun is vertical to the point i of the equinoctial ff , and from thence equally illuminates both the poles a and b , and all other places contained in circle $acdefg$ bb , (which, for the future, I shall call the solar horizon, because it divides the day from the night). Now as London moves round in the parallel ddl once in 24 hours, at sun-rise it will be at d , at noon at the point k , and at sun-set at dl ; but when the earth is at C, London will be at d at sun-rise, at d at sun-set, and at k at midnight. Likewise, you may observe, that just half the parallel is enlightened at once: therefore, our days and nights are at that time equal. Observe the like of any other place. When the earth is at B, it is summer with us, but winter with our Antipodes, then is the north pole a , and all the places within the polar circle cc , continually enlightened, without immersing under the solar horizon $c b$, as you may see the south pole $bb b$, at the same time, continually obscured, without any day. Then London is at d at noon, on k at sun-set, and at dl at midnight, where you may observe much greater part of the parallel ddl , contained in the enlightened, than in the dark part of the earth, which is the reason of our day's being so much longer than our nights at that time of the year.

But when the earth is at D, it is our winter, then is the north pole acc , involved in darkness, without any light (save that of the moon and stars), but at the south pole bbb , they have continual day. Then is London at dl at noon, on k at sun-rise, and at d at midnight. You may also note, that there is just as much of the parallel ddl , contained in the light part of the earth, as at B was contained in the dark part; by reason of which, our days, in winter, are just the same length as our nights are in summer.

By the third motion of the earth, we mean that motion by which the poles of the world revolve about the poles of the ecliptic, and occasion what is commonly called the precession of the equinoxes, or more properly, the retrogression of the earth's nodes. See the article PRECESSION.

As to the velocity of the earth's motion, and the figure and time in which it performs a revolution round the sun, see the articles PERIOD and ORBIT.

Quantity of Matter in the EARTH. This arduous

duous problem can only be solved by the principles of gravitation. We know the force of gravity towards our earth, by the descent of heavy bodies, or by calculating how much the moon falls below the tangent of her orbit: also by computing, from their motions, how much a primary planet falls below its tangent in a given time, and how much any of Jupiter's and Saturn's satellites fall below their tangents in the same time, we are able to determine the proportion which the gravity of a primary planet to the sun, and of a satellite towards its primary, bears to the gravity of the moon towards the earth, in their respective distances. Then, from the general law of the variation of gravity, the forces that would act upon them at equal distances from the sun, Jupiter, Saturn, and the earth, are computed; which give the proportion of the quantities of matter contained in these different bodies; that is, if we suppose the matter of the sun to be 1, the quantities of matter in Jupiter, Saturn, and the earth, will be respectively $\frac{1}{1047}$, $\frac{1}{7531}$, $\frac{1}{105223}$.

The quantities of matter in these bodies being thus determined, and their bulk being known from astronomical observations, it is easy to compute their different densities. Thus, the densities of the sun, Jupiter, Saturn, and the earth, have been computed to be respectively as the numbers 100, 94 $\frac{1}{2}$, 67, and 400.

Theory of the EARTH. The earth in its natural and original state, Des Cartes, Burnet, Woodward, and Whiston, suppose to have been perfectly round, smooth, and equable; and they account for its present rude and irregular form principally from the great deluge. See the article DELUGE.

M. de Buffon, arguing from the spheroidal figure of the earth, and the laws of hydrostatics, supposes that the earth, as well as the other planets, are parts struck off from the body of the sun by the collision of comets, and consequently, when the earth assumed its form, it was in a state of liquefaction by fire. Of this, says he, we will be the more easily convinced, when we consider the nature of the matter contained in the body of the earth, the greatest part of which, as sand and clays, are vitrified, or vitrifiable substances; and, on the other hand, when we reflect upon the impossibility of the earth's being ever in a state of fluidity produced by water, since there is infinitely more land than water; and besides, water has not the power of dissolving sand, stones, and other substances of which the earth is composed. How far the inequalities in the face of the earth, the beds of rivers, lakes, &c. and the various strata in its internal parts, serve to confirm this hypothesis, may be seen in *Histoire Naturelle*, &c. tom. 1. by M. de Buffon, and in the articles MOUNTAIN, RIVER, STRATA, &c.

Diameter of the EARTH. See DIAMETER.

Latitude of the EARTH. See LATITUDE.

Longitude of the EARTH. See LONGITUDE.

EARTH, in gardening and husbandry, if good, may be known by the sight, smell, and touch. First, by the sight. Earth that is of a bright chestnut or hazley colour, is accounted very good; of this colour are the best loams, and also the best natural earth; and this will be the better yet, if it cuts like butter, and does not stick obstinately, but is short, tolerably light, breaking into small clods, is sweet, will be tempered without crushing or chapping in dry weather, or turning to a mortar-like substance in wet. Next to this, the dark grey and russet earths are accounted the best: the light and dark ash-coloured are reckoned the worst; such as are usually found on common or heathy ground: the clear tawny is by no means to be approved; but that of a yellowish red colour is reckoned the worst of all; this is common in wild and waste parts of the country, and for the most part produce nothing but furze and fern, according as their bottoms are more or less of a light and sandy, or of a shingley gravel or clayey nature.—Secondly, by the smell. All earths that are good and wholesome will, after rain, or breaking with the plough or spade, emit a sweet smell.—Thirdly, by the touch. By this means we may discover whether it consists of substances entirely arenaceous or clammy; that is, whether it be harsh, gritty, porous, or friable; or tender, fat, detersive or slippery; that earth being always the best that is between the two extremes, and is neither too uncious or too lean, but such as will easily dissolve, and is of a just consistence between sand and clay; a loam or brick earth where cattle are accustomed to feed, requires little help or improvement but the plough or spade.—Barren earth is to be known divers ways; as, when instead of good green grass and a plentiful crop, it produces a thin, pale, small grass; also broom, furze, heath, moss, &c. denotes barren land, especially if they be small. Lands situated near the sea coast are often barren, being poisoned and starved by the vapours and storms proceeding from thence. On the contrary, good earth is known where it naturally produces mallows, docks, hemlock, and other weeds of the like nature; for such plants delight in fat deep earth; and it is ever to be observed, that such soil as produces weeds or grass luxuriantly, is undoubtedly rich and fruitful. For a further account of the different sorts of earths, see the articles CLAY, LOAM, SAND, &c.

EARTH, in chemistry, the fourth of the chemical elements, or principles, into which bodies are resolvable by fire.

EARTH-BANKS, in husbandry, &c. are a very common fence about London, and in several other parts of England. Where stones are not to be had cheap, these are to be preferred to all other fences, both for soundness and duration.

The best manner of making them is this: dig up some turf in a grassy place, a spit deep, or nearly
U the

the breadth of the spade, and about four or five inches thick; lay these turfs, with the grass outward, even by a line on one side, and on the back-side of these lay another row of turf, having a foot space of solid ground on the outside, to prevent the bank from slipping in, if it should be any ways faulty. On the outside of this make a ditch, or else let the sides be lowered both ways with a slope two feet deep, and there will be no pasture lost by the fence, because it will bear grass on both sides.

The earth that is dug out of the ditches, or from the slope, must be thrown in between the two rows of turf, till the middle is made level with the rest: then lay on two more rows of turf in the same manner; and with more of the earth fill up and make level as before. Let this method be continued till the bank is raised four feet high, or more, if necessary, only observing, that the higher it is to be carried, the wider the foundation must be made. As the bank is carried up, the sides must not be raised perpendicular, but sloping, inward both ways, so that at the top it may be about two feet and a half wide. This sort of fence, when made with less care, and faced with clay, is left naked, and serves very well in some places; but, when it is thus managed with the turf, the joinings of the several pieces are hid in a little time, by the growth of the grassy part of the turf on each side, and it makes a beautiful fence, of as green and pleasant a colour as the rest of the field.

EARTHING, in gardening, signifies covering the roots of plants with earth, as is practised with asparagus, or banking against their sides with earth, in order to blanch their leaves, as is done with celery, &c. or drawing the earth up to the plants with a hoe, as is practised with peas, beans, cabbages, &c.

EARTHQUAKE, in natural history, a violent agitation, or trembling, of some considerable part of the earth, generally attended with a terrible noise like thunder, and sometimes with an eruption of fire, water, winds, &c.

Earthquakes are allowed to be the greatest and most terrible phenomena of nature, there being no security against their effects, when they come with the last degree of violence.

There are two sorts of earthquakes; the one caused by the action of subterraneous fires and the explosion of the volcanos, which are not felt but at small distances, and at the times that the volcanos are agitated, or before they begin to open; and the other from air. When the materials that form subterraneous fires come to be fermented, heated, and inflamed, the fire makes efforts on all sides; and if it does not naturally find an out-let, it raises the earth, and makes a passage for itself by throwing it off, by which means a volcano is produced, the effects of which are repeated, and they last in proportion to the quantity of inflammable matter it con-

tains; if this matter be inconsiderable, there may happen a raising of the ground, a commotion, and an earthquake, without any volcano being formed by that means: the air, produced and rarefied by the subterraneous fire, may likewise find small outlets by which it may escape; and in this case there will only happen an earthquake without any eruption, or volcano. But when there is a large quantity of inflammable matter, and when it is locked up and confined by solid and compact substances, there happens a commotion and volcano too: but all these commotions cause no more than the first sort of earthquakes, and can only shake a small space of ground. A very violent eruption, for instance, of Mount *Ætna*, will cause an earthquake over the whole island of Sicily; but it will never extend to three or four hundred leagues distance. When some new vents of fire have been formed in Mount *Vesuvius*, there are felt at the same time earthquakes at Naples, and in the neighbourhood of the volcano; but these concussions have never shaken the Alps, nor been communicated to France, or other countries remote from *Vesuvius*: in this manner earthquakes, produced by means of volcanos, are confined to a narrow space; which is properly the effect of the re-action of the fire, and they shake the earth, just as the explosion of a powder magazine causes a sensible concussion at several leagues distance.

But there is another sort of earthquakes very different as to their effects, and, probably as to their causes; and these are such as are felt at considerable distances, and which shake a long tract or slip of ground, without any volcano or eruption appearing. We have instances of earthquakes that are felt at the same time in England, France, Germany, and even in Hungary; and these always extend a great deal more in length than in breadth; they shake a tract of ground with more or less violence in different places; and they are almost always accompanied with a dull noise, much like that of a large carriage that rolls along swiftly.

In order to understand thoroughly what may be the causes of this kind of earthquake, we must remember that all inflammable matters capable of explosion, such as gun-powder, generate a large quantity of air; that this air, produced by the fire, is in a state of very great rarefaction; and that by means of this compression, in which it finds itself in the bowels of the earth, it must produce very violent effects. Let us, therefore, suppose, that at a very considerable depth, as a hundred or two hundred fathoms, there be found pyrites and other sulphureous substances; and that by the fermentation produced by the filtering of the waters, or other causes, these happen to take fire, let us see what will be the result; in the first place, these substances are not regularly disposed in horizontal strata; on the contrary, they are contained in the perpendicular fissures, in the caverns

caverns at the foot of these fissures, and in other places where the water can act, and into which they can penetrate: these substances, coming to take fire, will generate a large quantity of air, whose spring being compressed in a little room, as in that of a cavern, will not only shake the superior ground, but seek for passages to escape by, and to extricate itself. The passages that present themselves, are the caverns and canals formed by the subterraneous waters and rivulets: the rarefied air will violently precipitate into all the passages that are open, and form a furious wind in these subterraneous cavities, the noise of which shall be heard at the surface of the earth, accompanied with concussions thereof; this subterraneous wind produced by the fire, will extend as far as these cavities, and cause an earthquake more or less violent, in proportion as it is remote from the fire, and finds passages more or less narrow: this motion being performed lengthwise, the concussion will be in the same direction, and the earthquake felt in a long zone or tract of ground. This air will cause no eruption or volcano, because it will find sufficient room to dilate itself, or, rather, because it will find outlets, and issue out in form of wind or vapour: and even should it be denied that there are actually any subterraneous passages, by which this air and these vapours may escape, we may easily conceive, that in the very place where the first explosion happens, the ground being raised up to a considerable height, the adjoining place must be divided and rent asunder horizontally, in order to correspond with the primary motion, which is sufficient to make passages that may communicate the motion to a very great distance. This explication agrees with all the phenomena. An earthquake is not felt in the very same instant in two distant places; for instance, a hundred or two hundred leagues: there is no external eruption of fire caused by these earthquakes that reach to some distance; and the noise that accompanies them, almost always points out the progressive motion of the subterraneous fire.

What has been said may be farther confirmed by connecting it with other facts. It is well known, that mines exhale vapours independently of the winds produced by the current of the waters, and that there are often observed in them currents of unwholesome air and suffocating exhalations; and besides, there are holes, abysses, and deep lakes on the earth, that produce winds, as the lake of Boleslaw, in Bohemia.

Earthquakes, it is true, are a great deal more frequent in places where volcanos are than elsewhere; as in Sicily and Naples, and it is well known from observations made at different times, that the most violent earthquakes happen at the time of the greatest eruptions of volcanos: *Buffon's Histoire Naturelle.*

Earthquakes may be produced artificially, by mixing equal quantities of sulphur and the filings of iron, and beating them together, with an addition of water, into a kind of paste; and burying the whole three or four feet under the surface of the earth; and in seven or eight hours time the earth will begin to tremble, crack, and smoke, and burst out into flames.

EASEL-PIECES, a denomination given by painters to such pieces as are contained in frames, in contradistinction from those painted on ciellings, &c.

EASEMENT, in law, a privilege or convenience which one neighbour has of another, whether by charter or prescription, without profit: such are passages through his lands, a fink, or the like. These, in many cases, may be claimed.

EAST, one of the four cardinal points of the world; being that point of the horizon where the sun is seen to rise when in the equinoctial. See COMPASS, HORIZON, EQUINOCTIAL, &c.

EASTER is the great festival of the anniversary commemoration of our Saviour's resurrection; which, for its antiquity and excellence, challenges the precedence of all others.

The Greeks and Latins call it *pascua*, originally an Hebrew word, signifying a passage, applied to the feast of the passover, held by the Jews much about the same time. In English it is called Easter, from a goddess of that name, worshipped by the Saxons in the month of April.

It was in conformity to the custom of the Jews, who were commanded by God himself to celebrate the passover in the first month, and on the fourteenth day of that month, in the even, that the primitive fathers ordered that the fourteenth day of the moon from the calendar new moon, which immediately follows after the twenty-first of March, at which time the vernal equinox happened upon that day, should be deemed the Paschal full-moon, and that the Sunday after, because our Saviour rose on the day after the Jewish passover, should be Easter-day; and it is upon this account that our Rubric has appointed it upon the first Sunday after the first full moon immediately following the twenty-first day of March, upon which day, at that time, the vernal equinox happened: whence it appears, that the true time of celebrating Easter, according to the original institution of the feast of the passover, as well as according to the intent of the council of Nice, was to be the first Sunday after the first full-moon immediately following the vernal equinox, or when the sun entered into the first point of Aries: and this was the principal view pope Gregory had, when he reformed the calendar, to celebrate Easter according to the intent of the Nicene council: and as the new-style has been ordered by act of parliament to be used in Great-Britain for the future, it will be necessary to shew the method

ECLECTICS, *Eclectici*, ancient philosophers, who, without attaching themselves to any particular sect, selected whatever appeared to them the best and most rational.

Potamon of Alexandria was the first of the eclectics: he lived in the reigns of Augustus and Tiberius; and being tired with the scepticism of the Pyrrhonians, he resolved upon a scheme that would allow him to believe something, but without being so implicit as to swallow any entire hypothesis.

ECLECTOS, the same with what is more usually called *linctus*. See **LINCTUS**.

ECLIPSE, in astronomy, a privation of the light of some luminary, by the interposition of an opaque body, either between it and the spectator's eye, or between it and the sun.

Should we enquire into the meaning of the word eclipse, it will be found a derivative of the Greek verb *ἐκλείω*, to faint or swoon away; for the Grecians say, that such persons as are troubled with a death-like fainting or swooning, are eclipsed, or do fall into an eclipse. Thus, also, the moon's body seems to vanish and grow dark, when deprived of the light of the sun, by the interposition of the earth. But we cannot apply this term to properly to the sun; because the sun receives its light from no other body; it alone is the great fountain of light and heat; therefore, we may more properly, and ought to say, that this phenomenon is an eclipse of the earth; because it is the earth that is deprived of the light of the sun by the interposition of the moon.

Eclipses of the luminaries are either solar or lunar. The solar is caused by the interposition of the moon, between the sun and the earth; by which means, some particular part of the earth is deprived of the sun's light for a certain space of time; though other places, at the same time, enjoy the full light of that great luminary. But the lunar eclipse is always universal, and appears in all places of the same quantity and duration; which is accounted for in this manner: the moon is an opacous body, and has no light but what she receives from the sun; and therefore cannot be eclipsed, or lose the light of the sun, but when she is in her full; when, it is known, she has little or no latitude, and moves diametrically opposite to the sun, and the earth interposing itself in a direct line, between them, casts its shadow upon the moon, and thereby deprives her of the sun's light, which may be more or less, according to the latitude of the moon.

In solar eclipses it is to be observed, that they always begin on the west side, and end on the east; because the moon, by her proper motion in longitude, from west to east, first enters upon the west limb of the sun. On the contrary, the lunar eclipses always begin on the east and end on the west side; for her motion being from west to east, the east part of her body must necessarily first enter the earth's shadow.

The sun is very seldom, but the moon is often, totally eclipsed. And the eclipse of the moon appears from all parts alike, as to quantity and duration; and a reduction for the difference of the meridians, will shew the beginning, middle, and end of any such lunar eclipse for any determinate place on the earth: but this cannot be done in the eclipse of the sun; because, at the same moment of time, it is less in one place than in another; in one part of the earth total, when in another part of the globe they have no eclipse at all, which is caused by the moon's vicinity to the earth, and sudden changes of her parallax in longitude and latitude, and the small proportion the moon bears to the sun and earth. To demonstrate which, let A (*plate XLIII. fig. 2.*) represent the sun and center of the world, and let BKR B represent the annual orb of the earth, R the body of the earth, SZVS shew the orb of the moon; Q is the place of the moon, when she is in conjunction with the sun; VX or Z shew the place of the moon when she is in opposition; D is the conical point of the earth's shadow, which is greater or less, according to the distance of the earth from the sun.

By which figure it appears, that the whole body, or the sun, by the interposition of the moon at O, is hidden from the sight of him that stands in the point between R and P: whereas only half the sun is obscured to him that stands at R; and there is no part of it hidden from him that stands at M.

This, I apprehend, may suffice to demonstrate the cause of eclipses of the sun in particular;

The moon being less than the earth, her shadow can never cover the whole globe, only a part of it, such as I H; and a total darkness happens only to those inhabitants on whom the shadow falls. The circumjacent places will be illuminated with some of the sun's beams, called the penumbra, or a lucid partial shadow; which will have different degrees of illumination, according to the distance from the center of the real shadow. The inhabitants where this penumbra falls, will only see a part of the sun's disk obscure, which will appear to be more or less, in proportion as they are situated nearer or farther remote from the center: without this penumbra, all the sun's body will be seen at the same time, and no eclipse perceived at all.

Let S (*fig. 3.*) represent the sun in the equinoctial, and E the earth; then will A be the moon conjoined with the sun to the south pole, B a true conjunction at the earth's center, or in the equator, and C the moon conjoined with the sun at the north pole.

Now it is manifest, when the moon is at B, her shadow falls in the torrid zone; and consequently must take away the sun's light from that part of the globe; when at the same time to the north and south poles only part of the sun's body will be darkened: and when the moon is centrally conjoined

at

at C, the sun may be totally eclipsed at the north pole, when at the same time to the south part of the world he is free from the least obscuration. Hence the penumbral cone is determined in this manner:

Let A (*fig. 4.*) represent the sun, E the moon, D the earth, C the moon's opaque shadow, and AED a right line joining the three centers; draw the line FG, from the superior limb of the sun to the earth's surface, touching the inferior limb of the moon; and the line HI from the inferior limb of the sun, touching the superior limb of the moon; and they will intersect each other in the point K; which point will be the vertex, and the line KN the axis of the penumbral cone: about which, if the line KG or KI be made to revolve, it will describe the limits of the penumbra upon the earth's surface, and is here represented by the faint shadow LM.

To know how much of the earth's surface can be involved in this penumbra, first, let us suppose the angle of the cone, as demonstrated by Dr. Keill, in his Astronomical Lectures, page 116, without sensible error, equal to the apparent diameter of the sun; then in the triangle KOE, right-angled at O, is given the semi-diameter of the moon OE, and the semi-angle of the cone OKE, to find the distance of the moon's center from the vertex K; which when known, added to the moon's distance from the earth, will give the whole height of the said cone from the earth's center: then in the oblique triangle DKL, are given the sides DK and DI, together with the angle DKI; hence will be found the angle NDI, whose measure is the arch IN, the semi-diameter of the penumbra upon the earth.

After the same manner may be found the quantity of the earth involved in the real shadow. But if the apparent diameter of the sun exceed that of the moon, the real shadow will not reach the earth: in this case there may be a central eclipse of the sun, but not a total one: this is called an annular eclipse; the moon's body appears in the sun's disk, surrounded by a bright luminous circle. Such an one was observed by Clavius at Rome, April 9, 1567; and such another passed over the city of Edinburgh, on February 18, 1736-7, in the evening.

As it is evident there can be no eclipse of the sun, but when the moon is in the change; for then only the moon is in opposition to the sun, and near the earth's shadow: so there can be no eclipse of the moon but at the time of the full. And since there is a new and a full moon every month, it will be proper to give a reason, why there is not also an eclipse at those times every month. If the moon's orbit lay in the plane of the earth's orbit, that is, if these two planes were to coincide in a plane passing through the sun, there would be a total eclipse of the moon at every full, and consequently a central eclipse of the sun at every change. This is improperly attributed to the sun, because it is really an

eclipse of the earth; for all the time the sun retains his own light without the least diminution, and only those inhabitants of the earth that are under the shadow of the moon, or of the penumbra, are truly eclipsed.

But the orbs of the earth and moon, being placed obliquely, and not both in the same plane, intersect each other in two points, called nodes, where the moon's orbit is found to be inclined to the ecliptic in an angle of about five degrees; therefore the moon may be in such a position from the nodes, as to pass the opposition or conjunction, either too high or too low to fall into the earth's shadow, or to have her shadow or penumbra fall upon the earth. Hence it is very possible every full and new moon may not be eclipsed. And it will farther appear, that no eclipse can happen but when the moon is near one of her nodes; consequently the quantity of the eclipse depends upon the distance from it: and of both kinds it may be either total, partial, or central.

Let E (*fig. 5.*) represent the earth, S, S, S, three different positions of the sun, and M, M, M, M, M, various places of the moon in her orbit; let us now suppose a conjunction or an opposition to be made at B or C, at both which places the moon happens to be exactly in the nodes; consequently, in either of them there will be a central eclipse. Again, let us imagine the true syzygy at D or E; in both those points the moon has considerable latitude, and can only produce a partial eclipse. Farther, if the moon be removed to G or H, there will be no eclipse at all. Thus, in any part of the moon's orbit, by knowing the moon's distance from either node, the limits of eclipses, both solar and lunar, may be easily determined; that of the sun will be found nearly 18° , and that of the moon 12° . Hence it is that eclipses of the sun, in general, are more frequent than those of the moon; although in any particular place they are much fewer.

Now from the horizontal parallaxes of the sun and moon, and their apparent semi-diameters, the possibility of a solar eclipse is thus determined:

Let A (*fig. 6.*) represent the sun, B the earth, and C the moon; then the angle HEG will be the apparent diameter of the sun, seen from the earth's center; and QER the apparent diameter of the moon, seen from the same place; and consequently her shadow: hence, LKM will be the penumbral cone, limiting the utmost extent of such an eclipse, and WZ the quantity of the earth's surface involved in the real shadow at the same time. Now to find the apparent diameter of the penumbra in the moon's orbit, we have given the points L and M, upon the earth's superficies; in which, when the moon is at C, the circles XQ and RT will represent the sun's apparent disk free from obscuration.

To the inhabitants at L the moon's north limb will just touch the sun's south one, and may here represent the beginning of an eclipse; when, at the sametime, to the people at M the moon's upper limb will just go off the sun's lower limb, representing to them the end of an eclipse.

Thus it appears, that the distance of the two centers, S and Y, is equal to the apparent diameter of the penumbra; wherefore upon F, with the sum of the semi-diameters of the sun and moon, equal to the angle FMY, describe the circle SY P, and it will represent the penumbra in the moon's orb.

It is to be observed, if in the above figure C represents the moon perpendicular to the equator, and N the north pole, M will be the north limit, and L the south limit of the said eclipse. Again, to find the apparent diameter of the earth's disk in the moon's orb, you have given the horizontal parallax of the sun NDE, and EFN, the horizontal parallax of the moon; draw the line IO parallel to DKE, then will the angles EDN and DNI be equal. Therefore out of the angle FNO, equal to the moon's horizontal parallax, take the angle TNO, that of the sun, and there will remain the angle ENT equal to the apparent semi-diameter of the earth's disk in the moon's orb. Hence upon the center F, with the difference of the horizontal parallaxes of the sun and moon ENT, describe XV T, and it will represent the same.

Now, as was said before, if none of this penumbra fall within the said disk, there can be no eclipse: for let E (fig. 7.) be the disk in the ecliptic, and F the penumbra in the moon's orbit, Fg is the distance of the luminaries from the node: here it is plain that the moon's latitude is greater than the sum of the semi-diameters of the disk and penumbra, and therefore no eclipse can happen to that part of the moon's orbit: but if the sum of the semi-diameters of the disk and penumbra be greater than the moon's true latitude, as at C, than an eclipse must unavoidably happen to some place: and if the moon's latitude be less than the semi-diameter of the disk, as at B, the eclipse will be central, and somewhere may be total. And further, if all the penumbra fall within the disk, as at A (fig. 7.) the same for some time may be general. It is to be noted, that in partial eclipses the center of the penumbra falls without the disk.

We shall next give the method of constructing solar eclipses geometrically: but before we can do this, we must have the following elements calculated from astronomical tables; and as examples are found to convey any thing of this intricate nature in a more familiar manner than precepts alone, we shall give a construction of the solar eclipse, which will happen the 5th day of August next (1766), from tables which have undergone the strictest examination, and have very seldom been known to err a minute from the truth.

1. True time of the ecliptic conjunction, Aug. 1766, apparent time	5 ^d 5 ^h 42 ^m 12 ^s
2. True place of the ☉ and ☾ at that time Ω	13 ^o 9' 52"
3. Moon's lat. north	0 ^o 32' 36"
4. Moon's horizontal parallax	0 ^o 53' 55"
5. Sun's declination	16 ^o 53' 17"
6. Sun's true horary motion	2' 24"
7. Moon's ditto	29' 25"
8. Sun's semi-diameter	15' 47' 5"
9. Moon's ditto	14' 42' 5"
10. Angle of the moon's visible way	5 ^o 14' 48"
11. Sun's horizontal parallax	0 ^o 0' 9"
12. Lat. of Greenwich	51 ^o 28' 39"

1. Take the sun's parallax from the moon's, gives 53' 46", which take from a scale of equal parts, so large as to give $\frac{1}{2}$ of an inch at least to every minute of parallax, and with this extent, as a radius, describe the semi-circle AEB (plate 44, fig. 1.) from the center S; which semi-circle shall represent the northern half of the sun's enlightened disk.

2. Upon the center C raise the straight line CH, perpendicular to the diameter ACB; so ACB shall be a part of the ecliptic, and CH its axis.

3. Being provided with a good sector, open it to the radius CA in the line of chords; and taking from thence the chord of 23 $\frac{1}{2}$ degrees in your compasses, set it off both ways from H, to g and to h, in the periphery of the semi-disk; and draw the straight line gVh, in which the north pole of the disk will be always found.

4. When the sun is in Aries, Taurus, Gemini, Cancer, Leo, and Virgo, the north pole of the earth is enlightened by the sun: but whilst the sun is in the other six signs, the south pole is enlightened, and the north pole is in the dark.

5. And when the sun is in Capricorn, Aquarius, Pisces, Aries, Taurus, and Gemini, the northern half of the earth's axis CXII P lies to the right hand of the axis of the ecliptic, as seen from the sun; and to the left hand, whilst the sun is in the other six signs, as in this example.

6. Open the sector, till the radius (or distance of the two 90's) of the fines be equal to the length of Vb, and take the sine of the sun's distance from the solstice (43^o 9' 52") as nearly as you can guess, in your compasses, from the line of fines, and set off that distance of V to P in the line gVh, because the earth's axis lies to the left hand of the axis of the ecliptic in this case, the sun being in Leo; and draw the straight line CXII P for the earth's axis, of which P is the north pole. If the earth's axis had lain to the right hand from the axis of the ecliptic, the distance VP would have been set off from V towards b.

7. To draw the parallel of latitude of any given place,

place, as suppose Greenwich, or the path of that place on the earth's enlightened disk as seen from the sun, from sun-rise till sun-set, take the following method:

Subtract the latitude of Greenwich, $51^{\circ}\frac{1}{2}$ from 90° , and the remainder $38^{\circ}\frac{1}{2}$ will be the co-latitude, which take in your compasses from the line of chords, making CA or CB the radius, and set it from *b* (where the earth's axis meets the periphery of the disk) to X and Y, and draw the occult or dotted line XWY. Then, from the points where this line meets the earth's disk, set off the chord of the sun's declination $16^{\circ} 5' 3''$ to D and F, and to E and G, and connect these points by the two occult lines F XII G and DLE.

Bisect LK XII in K, and through the point K draw the black line VIK VI; then making CB the radius of a line of lines on the sector, take the co-latitude of $38^{\circ}\frac{1}{2}$ from the lines in your compasses, and set it both ways from K to VI and VI. These hours will be just in the edge of the disk at the equinoxes, but at no other time in the whole year.

With the extent K VI taken in your compasses, set one foot in K (in the black line below the occult one) as a center, and with the other foot describe the semi-circle VI 7 8 9 10, &c. and divide it into 12 equal parts; then from these points of division, draw the occult lines 7 *p*, 8 *o*, 9 *n*, &c. parallel to the earth's axis C XII P.

With the small extent K XII as a radius, describe the quadrantal arc XII *f*, and divide it into six equal parts, as XII *a*, *ab*, *bc*, *cd*, *de*, and *ef*; and through the division-points *a*, *b*, *c*, *d*, *e*, draw the lines VII *e* V, VIII *d* IV, IX *c* III, X *b* II, and XI *a* I, all parallel to VIK VI, and meeting the former lines 7 *p*, 8 *o*, &c. in the points VII VIII IX X XI, V IV III II and I; which points shall mark the several situations of Greenwich on the earth's disk, at these hours respectively, as seen from the sun; and the elliptic curve VI VII VIII, &c. being drawn through these points, shall represent the parallel of latitude, or path of Greenwich, on the disk, as seen from the sun, from its rising to its setting.

N.B. If the sun's declination had been south, the diurnal path of Greenwich would have been on the upper side of the line VIK VI, and would have touched the line DLE in L. It is requisite to divide the horary spaces into quarters, and, if possible, into minutes also.

8. Take the moon's latitude ($32' 36''$) from the same scale the semi-diameter of the earth's disk (CA) was taken from, and lay it down on the line CH from C to *x*.

9. With the radius C *x* on *x*, as a center, describe the arc Cy, and making that extent a radius on the line of chords, take therefrom the chord of the complements to the moon's visible way = $84^{\circ} 45' 12''$, and set it off from C to *z*, then through the points *x* and *z* draw the indefinite right line NS,

which will be the path of the penumbra's center over the earth's disk, the point *x* being the nearest approach of the center of the penumbra to the disk, and is therefore the ecliptic conjunction of the sun and moon.

Note. The moon's latitude is now north descending; had it been north ascending, the arc Cy must have been described from C towards the left-hand, and the complement to the angle of the moon's visible way set off in the same manner. It must also be remarked, that the inclination of the penumbra's path, with respect to the ecliptic AB, will be the same as now, had the moon's latitude been south descending, and the contrary way when south ascending.

10. Take the moon's true horary motion from the sun, $27' 1''$, in your compasses, from the scale CA (every division of which is a minute of a degree) and with that extent make marks along the path of the penumbra's center, and divide each space, from mark to mark, into 60 equal parts or horary minutes, by dots; and set the hours to every 60th minute in such a manner, that the dot signifying the instant of new moon by the tables, may fall into the point *x*, half way between the axis of the moon's orbit, and the axis of the ecliptic; and then, the rest of the dots will shew the points on the earth's disk, where the penumbra's center is at the instants denoted by them, in its transit over the earth.

11. Direct the points of your compasses to the same moments of time in the path of Greenwich and in the path of the penumbra, and try them backwards and forwards until you find those which are nearest to each other, which will be found at $6^h 17'$; this time must evidently be the middle of the eclipse, or greatest obscuration.

12. Take the sun's semi-diameter, $15' 47''$, in your compasses, from the same scale from which you laid down CA, (the semi-diameter of the disk) and setting one foot in the path of Greenwich at *m*, namely, at 17 minutes past VI, with the other foot describe the circle U T, which shall represent the sun's disk as seen from Greenwich at the middle of the eclipse. — Then take the moon's semi-diameter, $14' 42''$, in your compasses from the same scale; and setting one foot in the path of the penumbra's center, at 17 minutes after VI, with the other foot describe the circle V Z for the moon's disk, as seen from Greenwich, at the middle of the eclipse, or time of greatest obscuration; and the portion of the sun's disk which is hid or cut off by the moon's, will shew the quantity of the eclipse at that time; which quantity may be measured on a line equal to the sun's diameter, and divided into twelve equal parts for digits, and here will be found = $4\frac{1}{2}$ digits nearly.

13. Lastly, take the semi-diameter of the penumbra, $30' 30''$ from the scale within CA in your compasses; and setting one foot in the line of the pe-

penumbra's central path, direct the other foot toward the path of Greenwich, and carry that extent backwards and forwards, till both the points of the compasses fall into the same instants in both the paths: and these instants will denote the time when the eclipse begins at Greenwich.—The like method will shew at what time the eclipse ends at Greenwich, which will be found at 8 minutes past VII.

In this construction it is supposed, that the angle under which the moon's disc is seen, during the whole time of this eclipse, continues invariably the same; and that the moon's motion is uniform and rectilinear during that time.—But these suppositions do not exactly agree with the truth; and therefore, supposing the elements given by the tables to be accurate, yet the times and phases of the eclipse, deduced from its construction, will not answer exactly to what passeth in the heavens; but may be two or three minutes wrong, though done with the greatest care.—Moreover, the paths of all places of considerable latitudes are nearer the center of the earth's disc, as seen from the sun, than these constructions make them; because the disc is projected as if the earth were a perfect sphere, although it is known to be a spheroid. Consequently, the moon's shadow will go farther northward in all places of northern latitude, and farther southward in all places of southern latitude, than it is shewn to do in these projections.

We shall now give a method of computing solar or stellar eclipses without parallax.

Let the requisites for the eclipse be found and projected as before directed; but it is not necessary to project with great accuracy.

Then first (in Plate XLV. *fig. 1.*) we shall have $SC = SM \times \text{fine of lat. of the place, } \times \text{ by the cosine of the sun's declination, } \div \text{ by the square of radius;}$ where SM is equal the semi-diameter of the disk, and SC equal the distance of the transverse axis of the ellipse from the center of the projection.

Again, we shall have CN equal to $SM \times \text{by cosine of the latitude } \times \text{ fine of sun's declination } \div \text{ by the square of radius}$ where CN is equal the semi-conjugate diameter of the ellipse; and we have CX equal to $SM \times \text{cosine of the lat. and divided by radius;}$ where CX is equal to the semi-transverse axis of the ellipse.

Let it be required to find the distance of the sun and moon's centers at a given time, before the center of the moon passes the point P , suppose B the place of the moon's center at the given time, and H the place of the vertex or observer at the same time. Then let fall HE perpendicular to the transverse axis of the ellipse, (described by the vertex) and HA perpendicular to the conjugate. Then will $CE = HA$ be the fine of the hour from noon to the radius of the semi-transverse axis of the ellipse; and $HE = CA$ will be the cosine of the same hour, to the radius of the semi-conjugate axis; wherefore

SC and CA being found, SA will be known, and in the right-angled triangle SAH , the two sides SA and HA being given, the angle ASH , and the side SH may be found.

Also the angles ESL and MSE being given by the previous calculation, the angle PSH will be given. And in the right-angled triangle PSB , the side SP equal the nearest approach of the centers, which will be given by the calculation; and the side PB , which is the time from B , the place of the moon's center to its passage over the point P , turned into motion by the horary motion of the moon from the sun, from whence the angle PSB , and the side SB will be found. Then the angles PSH and PSB being known, the angle HSB will be also known: and in the triangle HSB , the sides SH and SB , with the angle HSB between them being given (by the theorem commonly used in the calculation of the geocentric places of the planets) we may find the other two angles, and the side $HB =$ the distance of the centers of the sun and moon at the given time. And if the distance thus found, be equal to the semi-diameter of the penumbra, equal the sum of the semi-diameters of the sun and moon, then that time is the beginning of the eclipse. But if it be either greater or less, we must proportion a time by the horary motion of the moon from the sun to be added to, or subtracted from it; and if we repeat the calculation for the time thus found, the beginning and the end of the eclipse may be found to great accuracy.

The angle $ZHd =$ the supplement of the angle BHS before found, is equal to the number of degrees from the zenith point of the sun to the point of the limb that is first touched by the moon's limb. The difference of declination of the point d where the moon's limb first touches the sun's limb from the center, or limb of the sun will be known; for let the prick'd line df be the parallel of declination on the sun's limb, then the angle ZHd , just before found, added to the angle $ZHU =$ the angle HSA , found by the foregoing calculation, will be $=$ the angle dHU the cosine, of which to the radius of $HU =$ the sun's semi-diameter is equal to Hf , the declination from the center. And the versed sine of the same angle to the same radius, is equal to EU the declination of the point d from the sun's limb. The same may be found at the end or any other phase of the eclipse.

When the line kb , perpendicular to the line of the moon's way, cuts the same time in the path of the vertex, and in the moon's way, then is the middle of the eclipse or greatest obscuration at that time; and if the angles of the triangle bSb be found as before directed, then bb at the middle of the eclipse will be a minimum, or the two angles SbP and SbH will be equal to a right angle, so will be equal to the semi-diameter of the penumbra $= bb$. And the lucid part cy will be equal the difference of the

the semi-diameter of the sun and moon $\mp bb$. And the angle which the prickled line connecting the cups forms with ZS the vertical line of the sun's diameter, is equal to the angle BHS — a right angle.

Of the general transit of an eclipse, &c. and how to find the time and particular place of the beginning, &c. of the general eclipse.

Let BRCN (fig. 2.) represent the earth's disk in the ecliptic, BC and FK, &c. the moon's way or passage of the penumbra over it, P the north pole. Now the time when the moon's center will be at FDIHME and R is required. In the first place, here is given $FO = KO$, the sum of the semi-diameters of the disk and penumbra; secondly, $DO = OE$, the semi-diameter of the disk; and lastly, MO, the nearest approach of the luminaries to the center of the disk, to find FOH and DOH, the two angles of incidence. By the solution of a right angled triangle, having found the reduction MH, say, As OP or DO is to the radius, so is HO to the sine complement of the angle HOF or DOH: then to find the semi-duration FH or HK, the analogy is, As the radius is to FO; so is the angle of incidence FOH to FH: or by Eucl. i. 47. $FH = \sqrt{FO^2 - HO^2}$. In like manner may be found $DH = HE$; which, if divided by the hourly motion of the moon from the sun, will give each respective arch in time; this added to, or subtracted from, the time of the greatest obscuration, will give the beginning and ending of the general eclipse, &c.

Now, to find the latitude and longitude of those places upon the earth, over which the center of the penumbra passes, O will be that place to which the sun is vertical; its latitude is always equal to the sun's declination; and its longitude, from the place to which the tables are accommodated, is equal to the time from noon in that place reduced into degrees and minutes: hence the position of the center is known; and consequently, by the doctrine of spherics, the latitude and longitude of any given point, such as G, D, I, H, M, E, or L, may be found. G is the place where the shadow first touched the earth; D the place where the center first comes on, I the point where the sun is eclipsed in the universal meridian; H the place where the center falls; M the nonagesimal degree; E the place where the center goes off from the earth; L the place where the penumbra leaves it.

The mean velocity of the shadow over the earth is always equal to the hourly motion of the moon from the sun in the moon's orbit, reduced into geographical miles.

Lunar ECLIPSES. The beginning, end, and middle of a lunar eclipse is found much the same as has been shewn of the sun's eclipse. However, having collected the previous elements, as mentioned be-

fore in the solar eclipse, take the following example of constructing a lunar eclipse.

1. Draw the right line ACB (fig. 3.) for part of the ecliptic, and CD perpendicular thereto for the southern part of its axis; supposing the moon to have south latitude.

2. Add the semi-diameters of the moon and earth's shadow together, and take this from the scale in your compasses; and setting one foot in the intersection C as a center, with the other foot describe the semi-circle ADB, in one point of which the moon's center will be at the beginning of the eclipse, and in another at the end thereof.

3. Take the semi-diameter of the earth's shadow in your compasses from the scale, and setting one foot in the center C, with the other foot describe the semi-circle KLM for the southern half of the earth's shadow, because the moon's latitude is south in this eclipse.

4. Make CD equal to the radius of the line of chords on the sector, and set off the angle of the moon's visible path with the ecliptic from D to E, and draw the right line CFE for the southern half of the axis of the moon's orbit, lying to the right hand from the axis of the ecliptic CD, because the moon's latitude is south descending.—It would have been the same way (on the other side of the ecliptic) if her latitude had been north descending; but contrary in both cases, if her latitude had been either north ascending or south ascending.

5. Bisect the angle DCE by the right line Cg; in which line, the true equal time of opposition of the sun and moon falls, as given by the tables.

6. Take the moon's latitude from the scale with your compasses, and set it from C to G, in the line Cg; and through the point G, at right angles to CE F; draw the right line PGN for the path of the moon's center.—Then, F shall be the point in the earth's shadow, where the moon's center is at the middle of the eclipse; G, the point where her center is at the tabular time of her being full; and H, the point where her center is at the instant of her ecliptical opposition.

7. Take the moon's horary motion from the sun in your compasses from the scale; and with that extent make marks along the line of the moon's path PGN: then divide each space from mark to mark, into 60 equal parts, or horary minutes, and set the hours to the proper dots in such a manner, that the dot signifying the instant of full moon may be in the point G, where the line of the moon's path cuts the line that bisects the angle DCE.

8. Take the moon's semi-diameter in your compasses from the scale, and with that extent as a radius, upon the points N, F, and P, as centers, describe the circle Q for the moon at the beginning of the eclipse, when she touches the earth's shadow at V; the circle R for the moon at the middle of the

the eclipse; and the circle S for the moon at the end of the eclipse, just leaving the earth's shadow at W.

The point N denotes the instant when the eclipse begins, the point F the middle of the eclipse, and the point P the end of the eclipse.

ECLIPTIC, in astronomy, is that circle which the plane of the earth would mark out where it supposed to be extended to the heavens.

This therefore is that which the sun seems to describe in his annual course.

To explain the generation and nature of the ecliptic, and its divisions, also of the secondaries of the ecliptic, and their uses, and the terms used in astronomy depending upon them.

1st. Suppose an observer placed upon the earth, by extending his sight every way equally, if not hindered, bounds the world by a spherical superficies concentric with himself, (that is, with the earth) and judges all remote objects, whose distance is unknown, though really very unequally removed from one another, to be placed as it were in the same concave spherical superficies; as for instance, he does the fixed stars, sun, and moon itself. This sphere, concentric to the earth and surrounding it, designed by the sight, and bespangled with the twinkling fixed stars, supplying the place of an absolute space, is considered at rest; while we abstract from the diurnal motion, whereby this entire sphere, or rather the whole heavens, are revolved from east to west in the same space of twenty-four hours. But since by reason of the annual motion of the earth about the sun, the sun seen from the earth seems to move forward daily towards the more eastern stars, the sun will seem to move in this immovable sphere or mundane space; and its path marked among the fixed stars is called the ecliptic, because the eclipses of the luminaries happen only in this line; as was shewn above.

Having once settled the ecliptic, it is evident that as all the orbits of the planets about the sun, are not in one plane, but each of the planets seen from the sun, makes an excursion, sometimes on this side, sometimes on that side of the way of the earth, marked among the fixed stars; so that the planets seen from the earth, make an excursion sometimes on this side, sometimes on that side of the ecliptic, and even in the same points of their orbits seem to run off variously, according to the different situation of the earth. But their greatest excursion is contained within the boundaries of ten degrees; the astronomers therefore have called that tract which the sun, moon, and planets seem to adorn with their motions, and which is a zone or belt, twenty degrees broad, (ten on each side of the ecliptic,) by the name of the zodiac, from the images of animals, which the fixed stars, in that tract, seem to represent. The number of the images, pitched

upon by them, is twelve; either because this number seems the fittest, for its being divisible into parts without a remainder, as two, three, four, six, and twelve; or because, while the sun seems to run through the zodiac, in the space of a year, there happen near upon twelve lunations, or the moon runs through all her phases twelve times. These parts of the ecliptic and zodiac are called signs, and their marks are, Aries γ , Taurus τ , Gemini π , Cancer σ , Leo ρ , Virgo μ , Libra ϵ , Scorpio ι , Sagittarius ξ , Capricornus ζ , Aquarius ω , pisces χ . Every one of these signs is again divided into thirty equal parts, so that the whole circle (like all others) is divided into three hundred and sixty. Though the ecliptic or any other circle has no beginning nor ending, properly speaking; yet astronomers begin their reckoning from the first point of Aries, which the sun is seen in when the days and nights are equal, and spring begins to the inhabitants of the northern hemisphere, which also is the point of the common intersection of the ecliptic and equator. The reckoning is made from γ to τ , π , and so on, till a return is made to γ , the beginning again towards the same way that the sun seems to move about the earth. And the motion or progress this way is said to be *in consequentia signorum*, or according to the order of the signs; namely, that according to which the sun, moon, and almost the rest of the planets seem to move: but that phenomenon, which is carried in the contrary order, or from τ to γ , or from γ to χ , is said to be moved contrary to the order of the signs, or *in antecedentia*.

Because the axis of the earth after several revolutions about the sun, goes a little off from a site parallel to that it formerly had, describing the superficies of a cone, the images of the stars have removed from the signs of the zodiac, to which they originally gave names. And this happens not upon the account of the motion of the stars or the ecliptic, but because the equator of the earth is moved together with the axis of the earth, so as that the intersections of the celestial equator, with the ecliptic, or equinoctial points, (and consequently all the points of the ecliptic, as they are expressible by numbers) remove *in antecedentia*; and the images or the fixed stars seem to be transferred, in respect of them, *in consequentia*.

If innumerable circles be supposed to be drawn through the poles of the ecliptic, cutting the ecliptic at right angles, which are called its secondaries, any point in the heavens may be referred to the ecliptic, by the help of them; that is, any phenomenon is understood to be in that point of the zodiac or ecliptic, in which such a semi-circle, passing through the phenomenon, cuts the ecliptic. And the phenomena that are after this manner referred to the same point of the ecliptic, are said to be conjunct, or in

conjunction; but such as are referred to the opposite points, are in opposition. If a quarter of the ecliptic lie between the points to which the appearances are referred, they are said to be in a quartile aspect, but if a third part of the ecliptic, in a trine aspect; lastly, if a sixth part of the ecliptic lie between them, they are said to have a sextile aspect.

Besides, an arc of the ecliptic intercepted between the beginning of Aries and the said point of intersection, and reckoned according to the order of the signs, is called, the longitude of that phenomenon or point, as the arc of a secondary, intercepted between the ecliptic and the said phenomenon or point of the heavens, is called its latitude; on which account these secondary circles are called circles of latitude. The latitude is either northern or southern; for the heavens are divided according to astronomers, by the ecliptic, (a celestial circle, because originally considered in the heavens) in the northern and southern hemisphere.

The obliquity of the ecliptic is one of the most important elements of astronomy, because it enters into the calculation of all spheric triangles, wherein the ecliptic and equator are concerned.

The obliquity of the ecliptic being equal to the sun's greatest declination, namely, when in the tropics; the meridian height of the sun's centre must therefore be observed with a good instrument on the day of the solstice, and its difference with the height of the equator at the place of observation will give the declination of the tropic. Or, more accurately; observe the sun's meridian altitude in each tropic, this will give their distance, half of which is the distance of each tropic from the equator, that is, the obliquity of the ecliptic.

Example. The true height of the sun's centre in the winter solstice 1743, was observed to be $17^{\circ} 40' 7''$; and in the following summer solstice 1744, it was found to be $64^{\circ} 37' 17''$. Their difference $46^{\circ} 57' 10''$ gives the sum of the declinations of the two tropics, half whereof $23^{\circ} 28' 35''$ is the obliquity of the ecliptic.

This obliquity being known, the relation of all the points of the ecliptic to the equator is determined by a very simple operation; that is, the right ascension and declination of these points are easily found.

Example. Let S be a given point in the ecliptic IC G, distant $28^{\circ} 0' 0''$ from the first point of γ , or C. Draw from the point S the arc SO perpendicular to the equator DCB, which is the declination of the point S, and the arc CO of the equator is its right ascension. Now, in the rectangled triangle OSC where the angle SCO is $23^{\circ} 28' 35''$, and the hypotenuse CS $28^{\circ} 0' 0''$, there is found OS = $10^{\circ} 46' 44''$, and OC = $25^{\circ} 59' 55''$, for the sun's right ascension and declination when in $28^{\circ} 0' 0''$.

Among the astronomical tables, some are found which give the right ascension and declination to every degree, and even to every minute of the ecliptic.

It has been a subject of controversy amongst astronomers, whether the obliquity of the ecliptic be variable or not; that is, whether the angle between the planes of the ecliptic and equator, continues always unchangeably the same, or is subject to alteration: it is also disputed among these writers who hold it liable to change, whether that change be regular or irregular. It is certain that the obliquity of the ecliptic is at present found to be above a third part of a degree less than Ptolemy has given it us. From Ptolemy's time down to Tycho, some observations have made it less, and others more, by a few minutes. They who will have the obliquity to have been always the same as it is at present, surmount all these difficulties, by throwing upon the inaccuracy of the observations of the ancients, and the imperfection of their instruments, all the differences found between them and the moderns: others think this is treating the ancients with too little respect; for though it appears by Ptolemy, that they did not pretend to observe more nicely than to a sixth part of a degree, and their instruments fell far short of those made use of by the moderns; yet it can hardly be imagined, they could be so greatly mistaken in a matter so easy to be known, and so well deserving their attention. As for those who suppose that the obliquity is subject to a sort of libration, increasing in some ages, and decreasing in others, they attribute a greater degree of exactness to the observations on which they ground this fancy, than they ought. Some have imagined that the obliquity has been always gradually decreasing, the planes of the ecliptic and equator growing continually nearer to a coincidence. This opinion, besides its being founded upon a comparison of ancient and modern observations, receives a good deal of support from the consideration of the figure of the earth.

Now, after proper allowances, the obliquity of the ecliptic comes out from the observations of the ancients above a third part of a degree greater than the modern astronomers have found it. Louville, after comparing all the ancient observations, was of opinion, that the obliquity of the ecliptic decreased at the rate of $1'$ in a hundred years, and, from a great number of observations of his own, about the year 1711, set it down $23^{\circ} 28' \frac{1}{2}$, which is $\frac{1}{2}$ a minute less than Flamsteed and De la Hire made it: he goes farther, and thinks he discovered it to be five seconds less in the year 1720, than he observed it in 1714. But, notwithstanding the great care with which his observations appear to have been made, such a degree of exactness, as is here pretended, is hardly credible.

A TABLE of the OBLIQUITY of the ECLIPTIC.

The letter F. on the side of the table intimates the observation to be taken from Flamsteed; R. from Ricciolus's Almagest; L. from Louville; and those without a letter are from the authors themselves.

The change in the obliquity of the ecliptic, which, very probably, may be caused either, 1, by a change in the inclination of the earth's axis, the plane of the earth's orbit continuing immoveable; or, 2, by a change in the plane of the earth's orbit, the axis of the earth continuing parallel to itself; or, 3, by a change both in the inclination of the axis and in the situation of the earth's orbit. The first of these seems most likely to be the case; for if we consider the shape of the earth, that it is an ob-

late spheroid, or a globe a little flattened like a turnep, having its diameter at the poles a little shorter than at the equator; and that, by reason of this figure of the earth, the attraction of the heavenly bodies will act upon it in the same manner as if it had a ring round the equator; and that the sun, being in the plane of the ecliptic, is perpetually pulling this ring, or the protuberant parts about the equator of the earth, towards a coincidence with the plane of the ecliptic; which action of the sun, together with the like attraction of the moon, is the cause of the precession of the equinoxes; and if this be considered, it will not appear improbable, that these actions of the sun and moon, which have a continual tendency to bring the plane of the earth's equator nearer to the plane of the ecliptic, should gradually diminish the angle between these planes. The moon indeed, being nearer to the earth, contributes more than the sun towards this effect, by her attraction; for though she be but twice a month in the ecliptic, yet since she is always near it, never deviating much above five degrees from that circle; and these deviations are as much towards the north in one half of her period round the earth as they are towards the south in the other; they will so balance one another, that the effect of the whole attraction of the moon will be pretty much the same, as if she were carried round the earth exactly in the plane of the ecliptic. However, all changes in the position of the ecliptic are not to be absolutely excluded; for, as the planets move round the sun in different planes, their mutual attractions must have a tendency to change the situation of all their planes, and bring them nearer to a coincidence with one another: but then the distance of the planets from each other is so great, that the change here mentioned may be so exceedingly small as not to become sensible in many ages.

ECLOGUE, in poetry, a little elegant composition in a simple natural style.

The word is derived from the Greek *εκλογη*, to select.

The eclogue, in its primary intention, is the same thing with the idyllium; but custom has likewise made some difference between them, and appropriated the name eclogue to pieces wherein shepherds are introduced; and idyllium to those written like eclogues, but without any shepherds in them.

The eclogue then is properly an image of the pastoral life; therefore the matter is low, and its genius humble. Its business is to describe the loves, sports, piques, jealousies, intrigues, and other adventures of shepherds; so that its character must be simple, the wit easy, and the expression familiar. The true character then of the eclogue is simplicity and modesty: its figures are neat, the passions tender, the motions easy; and though sometimes it may have little transports and despairs, yet it never rises so high as to be fierce or violent. Its narra-
tions

tions are short, descriptions little, the thoughts ingenious, the manners innocent, the language pure, the verse flowing, the expressions plain, and all the discourse natural.

The models in this sort of poetry are Theocritus and Virgil, who both have some eclogues of a lofty character: the eclogue, therefore, occasionally raises its voice. Yet M. Fontenelle esteems it a fault in some modern poets to have put matter of high concern in their eclogues, and made their shepherds sing the praises of kings and heroes.

Some imagine the name eclogue to have been originally applied to such poems as were written in imitation of others; such are the eclogues of Virgil, which are only imitations of Theocritus.

ECLOGUE is also applied to certain compositions in prose: such are those of Strabo, Diodorus, &c. in which sense the word signifies only an extract, or collection.

ECOUTE, in the manege, a pace or motion of a horse, when he rides well upon the hands and the heels, is compactly put upon his haunches, and hears or listens to the heels or spurs, and continues duly ballanced between the heels, without throwing to either side. This happens when a horse has a fine sense of the aids of the hand and heel.

ECPHORA, in architecture, commonly signifies the distance between the extremity of a member or moulding, and the naked part of the column, or any other part it projects from. Some authors, however, account for the ephora from the axis of the column, and define it to be the right line intercepted between the axis and the outermost surface of a member or moulding.

ECPHRACTICS, in medicine, remedies which attenuate and remove obstructions.

ECPIESMA, in surgery, a sort of fracture of the cranium, when the bones are much shattered, and, pressing inwardly, affect the membranes of the brain.

ECPIESMA, in pharmacy, signifies the mass remaining after the juices of vegetables have been pressed out; and, in this sense, is the same as magna. It sometimes further imports the juice pressed out.

ECTASIS, in grammar, the same with diastole. See the article DIASTOLE.

ECTHESIS, in church history, a confession of faith, in the form of an edict, published in the year 639, by the emperor Heraclius, with a view to pacify the troubles occasioned by the Eutychian heresy in the Eastern church.

ECTHLIPSIS, *ἐκθλιψις*, among Latin grammarians, a figure of prosody, whereby the *m* at the end of a word, when the following word begins with a vowel, is elided, or cut off, together with the vowel preceding it, for the sake of the measure of the verse; thus they read *mult' ille*, for *multum ille*.

ECTROPIUM, in surgery, is an inversion of the eye-lids, when they are so retracted that their interior red skin becomes prominent, and the eye cannot be sufficiently covered by them.

The word is derived from the Greek, *εκτροπιω*, to invert.

ECTYLOTICS, in pharmacy, remedies proper for consuming callosities. See the article CALLUS.

ECTYPE, in antiquity, is an impression of a medal, seal, or ring; or a figured copy of an inscription, or other ancient monument.

The word is derived from the Greek, *εκ τυπος*, resemblance; because it resembles the original.

ECU, or ESCU, a French crown; for the value of which see the article EXCHANGE.

ECUSSON, in heraldry, a little escutcheon.

EDDISH, or EADISH, the latter pasture or grass that comes after mowing, or reaping; otherwise called eagrass, earsh, and etch.

EDGINGS, in gardening, a series of plants set joining to each other round the edges or borders of flower beds. The principal use of edgings is to keep the earth in borders adjoining to gravel walks from being washed down in heavy showers, and thereby fouling the gravel; for which purpose there is no plant so proper as the dwarf Dutch box; though others are made use of, as daisies, thrift, thyme, &c. but as these are liable to decay in patches, and require annual or at least biennial replanting, we cannot much recommend them; but for those who are fond of an edging that bears flowers, there are none more agreeable than the double pheasant-eyed pink, or double daisy.

EDHELING, *Edelingus*, the same with Atheling. See the article ATHELING.

EDICT, *Edictum*, in matters of polity, an order or instrument, signed and sealed by a prince, to serve as a law to his subjects.

EDIFICE, the same with building. See BUILDING.

EDILE, or ÆDILE. See ÆDILE.

EDITOR, a person of learning, who has the care of an impression of any work, particularly that of an ancient author.

EDUCATION is the bringing up and forming the minds of children, either in point of learning or good manners.

The word is formed from the Latin, *educō*, to bring up.

EDULCORATION, in pharmacy, the same with dulcifying. See the article DULCIFYING.

EDULCORATION, in chemistry, is the sweetening or clearing of any matter from impurities, especially the salts it may be impregnated with; by washing it thoroughly in common water; so that it is the same with ablutio.

The word is derived from the Latin *edulcoro*, to sweeten, and that from *dulcis*, sweet.

EHRETIA, in botany, a genus of pentandrious plants, whose flower is monopetalous, the tube longer than the cup, and the border cut in five segments.

The fruit is an unilocular roundish berry, containing four seeds, convex on one side, and angulated on the other.

EEL, *Anguilla*, in ichthyology, a species of *muræna*. See the article *MURÆNA*.

EEL-BACKED, an appellation given to such horses as have black lists along their back.

EEL-SPEAR, a forked instrument with three or four jagged teeth, used for catching of eels: that with the four teeth is best, which they strike into the mud at the bottom of the river, and if it strike against any eels, it never fails to bring them up.

EFFECT is that which results from, or is produced by, any cause. See *CAUSE*.

EFFECTIONS, in geometry, are used in the same sense with the geometrical construction of propositions, and often of problems and practices, which, when they are deducible from, or founded upon, some general proposition, are called the geometrical effections thereunto belonging.

EFFERVESCENCE, in a general sense, signifies a slight degree of ebullition in liquors exposed to a due degree of heat. But the chemists apply it to that ebullition which is excited when two substances of different natures, an alkali, for example, and an acid, are mixed together. If the effervescence produces a heat in the substance so mixed, it is called a hot effervescence; but, if no heat is excited, it is a cold effervescence.

EFFICACIOUS, a term used by divines, in speaking of grace; importing such grace, as never fails to produce its effect. See *GRACE*.

EFFLORESCENCE, among physicians, the same with exanthema. See the article *EXANTHEMA*.

EFFLUENT FEVER, the same with an inflammatory one. See the article *INFLAMMATORY*.

EFFLUVIA, minute particles which exhale from bodies.

The word is derived from the Latin *ex*, from, and *fluo*, to flow.

EFFUSION, in a general sense, the pouring out of any thing liquid, and that with some violence.

EFT, in zoology, the English name of the common lizard, *lacertus vulgaris*, called also, in several parts of the kingdom, the newt and swift. See the article *LIZARD*.

EGG, *Ovum*, in natural history, a body formed in certain females, in which is contained an embryo, or fetus, of the same species, under a cortical surface or shell.

EGG, in architecture, is an ornament in that form, cut in the echinus or quarter round of the Ionic and

Composite capitals. The profile or contour of an echinus is enriched with eggs and anchors placed alternately.

EGG-PLANT, *melongena*, in botany. See the article *MELONGENA*.

EJACULATOR, a muscle of the penis, otherwise called the elevator.

EJECTA, a term used, by lawyers, for a woman disflowered, or cast from the virtuous.

EJECTION, in the animal œconomy, evacuation, or the discharging any thing through some of the emunctories, as by stool, vomit, &c.

EJECTMENT, *Ejectione Firma*, in law, a writ, or action, which lies for the lessee for years, on his being ejected, or put out of his land before the expiration of his term, either by the lessor, or a stranger. It may also be brought by the lessor against the lessee, for rent in arrears; or holding over his term, &c.

EIGHT, or **PIECE OF EIGHT**. See the article *EXCHANGE*.

ELABORATORY, the place where chemical processes are performed. See *CHEMICAL Laboratory*.

ELÆAGNUS, oleaster or wild olive, in botany, a genus of plants whose flower is apetalous, the cup is a monophyllous, quadrifid, rough, coloured perianthium, with four short filaments, topped with oblong incumbent antheræ. the fruit is an ovate, obtuse, and smooth drupe, including an oblong nut or kernel.

ELÆOSACCHARUM, in pharmacy, a preparation of some essential oil with sugar, thus performed: grind an ounce of dry loaf-sugar to an impalpable powder, in a glass mortar, and with a glass pestle, and by degrees add thereto a dram of any essential oil, or only half a dram, if the oil be very tenacious; and continue rubbing them together, till all the oil be thoroughly mixed, and drank in by the sugar. If a little fresh white of an egg be added in the grinding, the oil becomes thereby more easily miscible; but the mixture will not keep so long, without turning rancid.

If these elæosaccharums be well prepared, dried, and put into clean glasses, exactly closed with glass stoppers, they may be preserved a long time perfect. By this method, therefore, you may prepare an excellent medicine, rich in virtue: for if the elæosaccharum of mint be dissolved in distilled mint-water, then strengthened with the addition of spirit of mint, and the mixture sweetened with the syrup of the same plant, the whole virtues of mint may be thus obtained.

ELAPHOCAMELUS, in zoology, the same with the glama, or Peruvian camel. See *GLAMA*.

ELASTIC, in natural philosophy, an appellation given to all bodies endowed with the property of elasticity.

ELASTICITY, that power or property in natural bodies, by which they restore themselves spontaneously to the figure and dimensions which they had lost by the action of some other body applied to them.

Thus a spring or bow, when bent, restore themselves, by their elasticity to the form they obtained before any external force was applied to them. And thus the arteries of an animal body, after being distended by the impulse of the blood, contract and restore themselves, by their elasticity, to the same form and dimensions they had before they were thus distended. Some have endeavoured to solve elasticity by attraction only; as for example, if the string AB (Plate XLVI. fig. 1.) be considered as made up of particles lying over one another in the manner represented at ADB; it is plain that, if the point D be forcibly brought to C, the parts will be pulled from each other; and when the force that stretched the spring ceases to act, the attraction of cohesion, which was hindered before, will take place, and bring back the string to its former length and situation, after several vibrations. Now, though this seems to agree pretty well with the phenomena of a string in motion, it will by no means solve the elasticity of a spring fastened to one end, and bent either way at the other, like a knife or sword blade. For if such a spring be bent from A to a, (fig. 2.) the particles on the side C, which now become convex, will be farther asunder at F, while the particles at D, carried to the concave part E, will come closer together: so that the attraction, instead of making the spring restore itself, will keep it in the situation in which it is, as it happens in bodies that have no elasticity, where, perhaps, only attraction obtains. Thus a plate of lead, a plate of copper, and a plate of soft iron stand bent.

But the most probable way of solving the elasticity of springs, is to consider both a repulsive, and an attractive property in the particles, after the manner of the black sand, which is attracted by the load-stone, and has been shewn by the learned and ingenious professor Petrus Van Muschenbroeck to be nothing else but a great number of little load-stones.

The great law of perfectly elastic bodies, is, that their relative velocity will remain the same before and after collision; that is, perfectly elastic bodies will recede from one another after the stroke, with the same velocity that they came together. Many curious phenomena may be explained from this property in bodies.

If the ivory ball A, (fig. 3.) weighing two ounces, strike with the velocity 16 against B at rest, weighing also two ounces; the body B will move forward after this stroke with the velocity 16, A remaining at rest in its place: the reason of this is, that the body A loses one half of its motion by striking the equal body B, and the other half by

the elasticity of B, recovering its former figure. From this experiment, several pretty odd phenomena arise: thus, if a row of shovel-board pieces, that is, metalline cylinders of about half an inch in height, and two inches diameter, be laid upon a smooth table, and you take a single piece, and drive it against the row, the last piece off the row will fly off: for if A (fig. 4.) strike the row of pieces B, C, D, E, F, G, H, I, in the direction Aa, then will the last piece I, fly off to i, with the same velocity that A struck B: and whatever be the velocity of A, no other piece but the last piece I, will fly off. But if you take two pieces, as A and B, (fig. 5.) and strike them together against the row C, D, E, F, G, H, I, the two last pieces H and I, will fly off from the other end of the row with the same velocity that A and B made the stroke.

If three or more pieces are made use of to make the stroke, the very same number will fly off from the other end of the row; and it is to be observed, that the same will happen with equal elastic balls, suspended in a row by strings of the same length.

Again, if the elastic body A, (fig. 6.) weighing four ounces, strike the quiescent body B, weighing only two ounces, with a velocity equal to 12; then will the velocity of A, after the stroke, be 4, and that of B 16. Just the reverse of this happens, when a lesser body strikes against a greater; in which case, the striking or lesser body will be reflected with one fourth of its first motion, and the greater be carried forward with a motion which is as 16.

The magnitude and motions of spherical bodies perfectly elastic, and moving in the same right-line, and meeting each other, being given, their motion after reflection may be determined thus: Let the bodies be called A and B, and the respective velocities a and b ; then, if the bodies tend the same way, and A, moving swifter than B, follows it, the velocity of the body A, after the reflection, will be $\frac{aA - aB + 2bB}{A + B}$, and that of the body B = $\frac{2aA - bA + bB}{A + B}$; but if the bodies meet, then, changing the sign of b , the velocity of A will be $\frac{aA - aB - 2bB}{A + B}$, and that of B = $\frac{2aA + bA - bB}{A + B}$.

and if either of these happen to come out negatives, the motion after the stroke tends the contrary way to that of A before it; which is also to be understood of the motion of the body A in the first case.

ELATERIUM, in pharmacy, imports in general any purging medicine; but is particularly applied to those which operate with violence; hence the word was transferred to the wild cucumber and the preparations thereof. See MOMORDICA.

ELATERIUM, in botany, a name by which Boerhaave calls the momordica of other botanists. See MOMORDICA.

Elasticity.

Electricity.

Elasticity

Electricity.

Fig. 5.

Fig. 6

Electricity

Electricity.

ELATINE FLUELLIN, in botany, an annual plant which grows naturally among corn in several parts of England. It hath a white, single, descendent, slender root, with few fibres. The stalk is slender, and trails on the ground: this is hairy, and furnished with acuminate leaves, which are placed alternately with very short pedicles; at each joint proceeds a single flower of the ringent kind, ending in a tail behind, and in the fore part divided into two lips; the upper one of a yellow colour, and the under one purple. The flowers appear in June and July; and the seeds ripen in autumn.

This plant is used in medicine, and is accounted a great vulnerary, and good for hæmorrhages of all sorts. It is also said to cure the gout, cancers, leprosy, and king's evil.

ELBOW, in anatomy, the juncture of the cubitus and radius; or the outer angle made by the flexure, or bend of the arm. See **CUBITUS** and **RADIUS**.

ELBOW, in architecture, a term used for an obtuse angle of a wall, building, road, &c. which divides it from its right-line.

ELCESAITES, in church history, ancient heretics, who made their appearance in the reign of the emperor Trajan, and took their name from their leader Elcesai.

The Elcesaites kept a mean between the Jews, Christians, and Pagans; they worshipped but one God, observed the Jewish sabbath, circumcision, and the other ceremonies of the law. They rejected the Pentateuch, and the Prophets; nor had they more respect for the writings of the apostles, particularly those of St. Paul. They detested chastity and continence, and obliged their disciples to marry. They acknowledged a Messiah, whom they called their great king; but we do not know whether they meant Jesus Christ, or some pretended Messiah. They gave him a human form, but invisible; the dimensions of which were thirty-eight leagues in height, and so in proportion. They pretended that the Holy Ghost was a woman, and of the same size with the Messiah. They were much addicted to judicial astrology, magic, and enchantments: they held that it was lawful to renounce the faith with the lips, provided a man kept it in his heart.

ELDER, or **SENIORS**, in Jewish history, were persons the most considerable for age, experience, and wisdom.

ELDER is also a denomination still preserved in the presbyterian discipline. See the article **PRESBYTERIAN**.

ELDER, in botany. See **SAMBUCUS**.

ELEATICS, a sect of philosophers of Elea, founded by Xenophanes, a Colophonian. He held all things to be incomprehensible, but withal maintained many dogmatical assertions. He held that God is one, incorporeal, eternal, all sight, and all

hearing, no way resembling man: that this God is all things; that whatever is, is eternal; that there are infinite worlds, and those immutable and eternal; that there are four elements; that the stars are certain clouds, set on fire when they rise, and extinguished when they set; that all comets, falling stars, and the like, are clouds, kindled by motion; that the sun is a fiery cloud, extinguished in its eclipses; that the moon is a close, compact, and habitable cloud; that there are many suns and moons in the several climates of the earth; that the sun promotes generation, but the moon contributes nothing to it; that the sun goes forward infinitum, but to us seems to move circularly by reason of the great distance; that the clouds are a vapour drawn up by the sun; that the earth was first founded and rooted, as it were, in an infinite depth; that the soul is a spirit; and that all divination is false, &c.

ELECAMPANE, in botany, a large plant, with long, wrinkled, oval, acuminate leaves, serrated about the edges, pale green above, and hoary underneath, joined close to the stalk, which divides towards the top into several branches, bearing large yellow flowers of the radiated discous kind, followed by oblong seeds, winged with down: the roots are short and thick, somewhat unctuous to the touch, brown, or blackish on the outside, and whitish within. It is perennial, grows wild in moist rich soils, and flowers in June.

The fresh roots of elecampane have a weak, not very grateful smell; which, on thoroughly drying, and keeping them for some time, is greatly improved, and approaches to that of Florence orris. Chewed, they discover at first a kind of rancid glutinous taste, quickly succeeded by an aromatic bitterness, which by degrees becomes considerably pungent.

This root stands recommended as a diaphoretic, stomachic, for promoting expectoration in humoral asthmas and coughs, and for attenuating viscid juices in general, and disposing them to excretion: taken freely, it is said to gently loosen the belly, and increase the urinary discharge. The dose of the dry root in substance is from a scruple to a dram or two.

ELECT, *Electi*, among ecclesiastical writers, those whom God has chosen, or predestinated to be saved. See the article **PREDESTINATION**.

ELECTION, the choice that is made of a person, or thing, in preference of any other; as, in election of an emperor, of a pope, of a bishop, of members of parliament, &c.

ELECTION is also the state of a person who is left to his own free will, to take or do one thing or another, which he pleases.

ELECTION, in theology, signifies the choice which God, of his good pleasure, makes of angels and men for the objects of his grace and mercy.

ELECTOR,

ELECTOR, a person who has a right to elect or choose another to an office, honour, &c.

Electors are particularly, and by way of eminence, applied to those princes of Germany, in whom lies the right of electing the emperor; being all sovereign princes, and the principal members of the empire.

ELECTORAL CROWN, or CORONET. See the article **CROWN**.

ELECTORATE, a term used as well to signify the dignity of, as the territories belonging to, any of the electors of Germany.

ELECTRICITY, a power or property in some bodies; as amber, sealing-wax, &c. whereby they attract light bodies.

As the power and various phenomena of electricity, which of late have been invented and exhibited in experiments, have greatly amused mankind, and justly raised their wonder and surprize, it is but natural to expect they should appear very anxious about the causes thereof, or manner of accounting for it; and also extremely inquisitive concerning the uses that may be made of such an amazing efficacy.

As to the first of these particulars, viz. the cause of electricity, and the manner of accounting for its effects, there have been many hypothesis formed to solve them; but they have been chiefly invented by men, who have appeared to understand little or nothing of true philosophy; or else to have been so affected with novelty and singularity, that the principles they advance are more doubtful and mysterious than the causes and properties of the electric virtue they account for by them. We hear people constantly debating on this head, as if Sir Isaac Newton and his philosophy, had never been heard of, or read.

For my own part, I have been always persuaded we shall never arrive at the cause of electricity, unless we pursue our enquiries by the clue given us by that great man. That is to say, the nature, cause, properties, and effects of electric virtue, are explicable only on the principles of the Newtonian Doctrine of Light and Fire. This is therefore, in the first place, to be premised, and which I shall lay down under the following heads, viz.

First, We find by experience, that the parts of all bodies when agitated to a certain degree, do so act upon animal bodies as to excite the sensation of warmth or heat.

Secondly, Such an agitation or intestine commotion of the parts of bodies may be effected by various means; as friction, percussion, fermentation, vital motion, the action of light, &c.

Thirdly, The standard degree of warmth or heat, is that of an animal body; or, in other words, if the parts of any body have a greater motion than the parts of the animated body, as the hand, we say it is warm or hot; but if they have less motion

than those of the hand, we say they are cold. Lastly, if the motion of the parts are the same in both, we then say, such a body is neither hot or cold. And hence it appears, that the ideas of heat and cold are only in a comparative degree.

Fourthly, The parts of bodies when agitated, or heated beyond a certain degree, emit or throw off such fine subtle particles, or effluvia, which shine or excite the idea of light; and which therefore we generally call particles of light.

Fifthly, When the parts of the body are so violently agitated, that they not only throw off lucid particles, but also shine themselves, then we say, it is a body of fire, when the particles are not in a fuming state; but when they are, we call that lucid fume a flame of fire.

Sixthly, The intensity of the action of ignited bodies depends as well on the density, as the velocity, of the parts; and when both these are in an extreme degree, the momentum, or whole force of the heat becomes intolerable, and inconsistent with the state of a natural body; and its action is, in this case, what we call burning.

Seventhly, There are some cases where the parts may have sufficient velocity to appear lucid, but not be dense enough, at the same time, to burn.

Eighthly, The motion with which the parts of bodies are thus agitated to emit light, and heat, is of the vibrating kind; because the motions and directions of the particles in this case may become uniform, consonant, and harmonious; and all conspire to produce the effects which they could not do by a confused contrary motion of parts.

On these principles Sir Isaac Newton accounts very clearly for many of the wonderful phenomena of nature, especially of the phosphoreal and electrical kinds. For instance; the shining of sea-water in a raging storm; of quick-silver agitated in vacuum of wood, flesh, and fish, by putrefaction; the ignis fatui; of stacks of corn, hay, &c. by fermentation, growing wet, and firing; the glowing of some worms, insects, and eyes of animals, by vital motions; of phosphorus, by attrition, or the action of the acid particles of air; of iron hammered very nimbly, till it becomes red-hot; of the melted parts of steel struck off by a flint; of axle-trees fired by the rapid rotation of the wheels; and of the mixture of some sorts of fluids, producing great heat, accension, and explosion.

But most expressly and largely, he applies this theory to a general explication of the production of electricity. He tells us, the glass globe, by attrition with the hand, will shine, and emit such an electric vapour, as by striking against paper, cloth, or the finger, will be put into such an agitation as to emit light, and make the paper, &c. appear lucid, like a glow-worm; and in rushing out of the glass, it will sometimes push against the finger, so as to be felt. Thus far Sir Isaac.

The

Electricity.

Fig. 1. Electrometer.

Fig. 2. Electrometer.

The above theory of light and fire will, I think, be nearly sufficient to solve all the phenomena of electricity; which I shall enumerate in order as follows.

Phænomena I. The electric virtue consists in a fine subtil matter, emitted from some sorts of bodies under the circumstances of attrition, which bodies are called electrics *per se*.

Phænomen. II. This virtue will not be excited in some sorts of bodies, which therefore are called non-electrics.

Phænomen. III. This virtue repels all light bodies lying on the surface of that in which it is excited, which is termed the electrified body.

Phænomen. IV. This virtue attracts all sorts of light substances within the space of its action, and then repels them again from the electrified body.

Phænomen. V. It suffers not the body once repelled to approach the electrified body, till it has first touched some other body, and then it will again attract it.

Phænomen. VI. This virtue will run off upon, or be received by all non-electric bodies; but will be refused or restrained by all electrics *per se*.

Phænomen. VII. This virtue, when excited to a sufficient degree, appears lucid, and shines in the dark like a flame.

Phænomen. VIII. It is emitted with great velocity, attended with a snapping; or small, but fierce explosion.

Phænomen. IX. The eruption of electric fire to a non-electric body, condenses the said fire; and as this fire is in a less or greater degree, it appears of a bluish purple, yellow, or white colour.

Phænomen. X. It runs through any length of a non-electric body almost instantaneously.

Phænomen. XI. It kindles any inflammable vapours or fume, and thereby sets the body on fire that emits it.

Phænomen. XII. All the properties and effects of the electric virtue appear to be nearly the same, at any distance from the body in which it was first excited, and having passed through any number of intermediate non-electric bodies.

These are the principal phenomena of electricity, which we now proceed to give some account of from the principles of the above-mentioned theory. As to the first, there can be no doubt of the existence of such a subtil matter in the substance of bodies, or of its emission or effluvia, because it can be so easily demonstrated to the senses by experiments.

This subtil matter, or spirit, appears to be of an elastic nature, and acts by the reciprocations of its tremours, or pulses, which are occasioned by the vibrating motion of the parts of an electric body, excited by friction. Hence, as friction is necessary to excite a vibrating motion in the parts of bodies, in order to throw off the electric matter; it follows, that those bodies, whose parts, by friction, will not

conceive a vibration, or put into an uniform reciprocating motion, will not prove electrical, or be productive of electricity: and the defect seems to arise from the want of a natural elasticity of the particles of the body. Thus the white of an egg in its natural state, or boiled to a greater consistence, is a non-electric; but when it is thorough dry and hard; it is then as brittle and yellow, and as electrical as amber itself.

Nor is it any thing less than the highest degree of elasticity in bodies that renders them capable of those vibrations which put the electric matter into action. For we observe the white of an egg boiled, and the strongest glues, when cold, are considerably elastic; yet are utterly non-electrical; even tempered steel itself, though so greatly elastic, shews no signs of electricity. In short, nothing less than that degree of elaterium, which makes bodies brittle, and break with a polish, as in glass, amber, rosin, pitch, wax, &c. will constitute them electrical.

The electric matter, as it is emitted from the body, enters into, and possesses every light non-electric body it meets with in its way, and carries it by impulse in its direction, viz. from the electric body, this we call the repulsive power of electricity. This electric spirit having impregnated the light body, and wholly possessed it, begins there to form a new sphere of action, or vibration; whose pulses being in a contrary direction to those of the electrical body, will cause the said light body to keep every where beyond the sphere of its activity, or to be constantly repelled by it. This is very evident by experiment.

Hence it is, that when two or more bodies are possessed of the same power, at the same time, they always repel each other; so the plumulæ of feathers, while the electric virtue is among them, repel each other. Thus it is also in magnetics; two needles touched on the same pole of a load-stone, repel each other, if put together by their touched ends on the surface of water, or suspended on the points of needles.

Hence also it is, that the electrical virtue will not run off the electrified body to another which is an electric *per se*; for though an electric body, in order to emit this virtue very copiously, must be excited by friction; yet we are to understand, that all electrics *per se* have naturally a vibrating motion of the parts, by which they emit this virtue in a less degree, and imperceptibly; and so have each a proper sphere of action; and the pulses of each sphere being in contrary directions, cannot conspire and unite, but must restrain and prohibit each other. Thus the flame at the end of the iron, at the approach of a match, retires, and seems repelled by the contrary action of the brimstone, while it is greatly dilated at the distant approach of the finger, and rushes against it with a blast. Thus also it is in magnetics

neties *per se*; for two loadstones placed on the water in basons, or suspended by strings, with their two similar poles together, will always repel each other. Therefore it is, that when we would conduct or communicate the electric virtue to any great distance by the mediation of any non-electric body; the said body is either suspended by silken strings, which are electrical, or laid on cakes of rosin, that the virtue might not run off thereby.

The electric virtue in that part of its vibration, by which it returns to the excited body in each pulse, meeting with light bodies in its way, impels them forcibly towards the electric body, and makes them appear to be attracted by that body; and so this is called the attractive power of electricity. But here it may be remarked, that electric bodies, if light, as well as others, are attracted; true, they are, but then they are not excited, and their natural vibration, or action, being very weak, will be overcome by the power of the excited and stronger electricity, and so carried or moved in its direction. It may likewise be farther objected against what I advanced above, that the natural efficacy of the silken strings should be too weak to restrain the excited electricity from entering its substance, and running off by it; but to this I answer, in the silk there is naturally a sphere of action or vibration; in the electricity of the electrified body there is none, till it begins to be emitted from the extremity, or some other part; all the motion that it has in the electrified body being that which it first received from the excited body, and is continued and propagated in the electrified body by the natural vibration of its parts, which is weaker than that in the silk, and therefore it must pass on by it, to make its exit at the end.

As to the lucidity of the electric effluvia, nothing more is requisite thereto, but a certain degree of velocity, which is easily produced by attrition, according to article 4th of the Theory.

In order to account for the snapping or explosion of the eruption of the electric fire, it is to be observed, that this explosion, like all others, consists in a violent concussion of the air, by a sudden expansion and bursting of the dense stream or profluvium of the fire, in striking against the non-electric body. Yea, sometimes it will snap against, or in the air only, as when it rushes out of the mercurial phial through the pores of sealing-wax. Now this explosion must arise from that violent action among the electric particles which proceeds from the extreme degree of velocity that constituted a dense body of liquid fire, (for it never snaps but in such a case) and by that action, as it becomes more dense, it becomes elastic; and at length, by dashing against the surface of any body, it is more and more condensed, and the innate elasticity so far increased, as to cause it to burst, explode, or flash away in an invisible vapour. And perhaps this, more adequate-

ly than gunpowder itself, represents to us the true cause of lightning and thunder; nor can we here suppose the effects of sulphur excluded; for as most metallic substances, so iron in particular, contains a great admixture of sulphur; now some of those sulphureous particles may, by the intense action of the electric fire, be dissolved and carried with it into the air, where the nitro-acid particles may conduce to the accension, and promote the explosion we are speaking of. And hence it may be, that the communication, action, and explosion, from iron substances, are much more considerable than can be produced from any other.

Where the electric fire is not so much condensed as to snap, or explode, it goes off in a large dilated stream of purple flame, and greatly resembles the corrugations of the aurora borealis, especially that part of the aurora which appears in a constant streaming light.

When the electric fire is but a little dense, it appears of a bluish colour, as all other faint lights do; thus the moon-light, which is extremely weak, appears blue in candle-light: and when the said fire is a little more dense, it appears of a purple hue, and has a greater effect; a still greater density makes it look yellow, like candle-light; but the greatest density is shewn by a yellowish white, like the sun's light, and then it produces the greatest force of explosion and percussion. As yellow lightning vanishes in an innocent flash; but white and dense lightning produces terrible effects. So also phosphorus, while agitated by a gentle friction, spends itself in a lambent innoxious blue flame; but when its action is heightened by a greater attrition or concussion, it kindles into a white flame, and burns with an outrageous and unquenchable fire. Therefore the phenomena and effects of electricity, lightning, and phosphorus, seem to be of a homologous nature, and to have something that is essential and common to each.

That the electric fire should shew itself, and produce its effects at any indefinite distance from the excited body, is nothing strange or unaccountable, when we consider it as a propagated fire, and of a similar nature to lightning; for fire of this sort loses nothing, but rather is increased by its propagation, with respect to its efficacy. As lightning pervades soft and yielding substances unhurt, and proves the dissolution only of hard and compact bodies, so electricity is not felt in the soft and muscular part of the body, but strikes the harder bones with a burning shock. And as those denser parts of lightning, which we call thunder-bolts, strike against hard bodies, and glance by reflection to different parts, so the fire of electricity striking against the lower part of the humerus, at the elbow of one arm, seems reflected from thence across the breast to the elbow of the other arm, and from thence flies out of the body, if nothing be near it; but if several join hands.

hands, it is almost instantaneously reflected from one to the other, through the arms and elbows of the whole company, be they ever so many. Lastly, as lightning does instantly deprive an animal of life, by its deliterious stroke, when sufficiently dense, so the electric emanation may be so condensed, and its force so encreased, as to strike a bird quite senseless, and sometimes quite dead, in a moment. The parallel might be carried yet farther, between lightning and electric fire; but I have not room to enlarge.

Thus I have proposed what I have to say, for a solution of the several phenomena of electricity; for the most part of which, I have the authority of an excellent theory, and the suffrage of a great many explicit and demonstrative experiments, which I have subjoined for farther satisfaction and entertainment of the reader. These experiments are such as I daily shew in my course of philosophy, and are therefore, indisputable facts, and topics of argumentation.

But now I am reduced to the arduous task of answering this very common and important question: "What is the use of this most wonderful and surprising property of bodies?" Not but that my answer is very short, and if it were to be but once or twice repeated, would be very easy, viz. That at present I know so little of its use, as not to be able to form any rational conjecture about it. What we know of this kind must be discovered by experience. And as I am fully persuaded all the powers of natural bodies were designed to answer very great purposes, yet what they are, are not discovered to us all at once, but by slow degrees. True philosophy was but dawning a century ago; and can we think it strange that any thing should yet appear abstruse or difficult to account for? I rather wonder we have been able, in so short a time, to discover so much relating to the uses that may be made of it. As for instance, the analogy between the fire of electricity and lightning; between its snapping and thunder; between their forces and effects on animal bodies, and animal life; between electricity and common fire, in respect of velocity and combustion; between electricity and phosphorus, in regard of its various degrees of light, colour of light, and manner of burning. Moreover, we know it has a considerable influence on fluid substances: a glaring instance is that of the syphon, and sponge; by which it appears, that fluids in motion, have their motion greatly accelerated by the electric virtue. Thus, if a vein be opened in a person electrified, the effluent blood will project to a much greater distance, than it would otherwise do: and is not this a promising indication of some great use that may be one time or other derived to the animal œconomy from electricity?

Yea, farther, I know from my own experience, that distant persons are affected by the electric vir-

tue in a very different manner; some prove extremely electrical, others very little susceptible of it; and it has been found that a person possessed with the infection of the small-pox, could by no means be electrified at all. These are early and interesting discoveries, and plainly intimate this wondrous efficacy was intended for something more than meer amusement to mankind. What relation it has to the animal spirits, or that which we mean by that term, in animal bodies, I know not, but must leave to older and wiser heads to determine by a longer course of experiments. What I have said, I submit to the judgment of those whose province it is to apply the discoveries of natural philosophy to the utility and benefit of mankind. My business is chiefly to make the experiments, which I shall now proceed to describe in all their proper circumstances, as they are performed on a machine, consisting of a large wheel and glass globe, or spheroid, fixed in a large long frame of wood, made in most respects like that of Mr. Monnier, but more easy in operation, by means of friction wheels, on which the axle of the great wheel turns; the rest of the apparatus will be mentioned in the sequel of the following experiments:

Experiment I. On the axis, in the center of the globe, is fixed a circular string of threads, at small distances from each other; and when the globe is at rest they all hang down by their gravity; but when the globe is put in motion, and a little heated, they all extend themselves from the center to the circumference, or inner surface of the globe, which they very nearly touch, in right-lined directions, so as nearly to represent the spokes of a coach-wheel. This they do by the electric virtue acting strongly upon them from the inner surface of the globe. And in this condition they will continue till the virtue ceases, and the globe becomes cold, when they gradually fall down, and take their first perpendicular directions.

Exp. II. The globe being whirled round, and the threads expanded as before, if the hand or any non-electric body be moved towards the surface of the globe, the threads within will seem immediately sensible thereof; and, as if animated thereby, will, in a very wonderful manner, move every way to the hand, by a motion like that we observe in the legs of a spider, especially that sort we call a carter, or father-long-legs. By this experiment we observe, the surprising nature and subtilty of this kind of effluvia, as it is seen to penetrate and pervade the substance of glass with the same readiness and freedom as if nothing were in the way to intercept it.

Exp. III. A hoop of fine threads being placed any how about the globe in motion, will have all the threads drawn out of their natural perpendicular directions into others which pass through the center of the globe, and so will be all perpendicular to the surface, which makes a very pleasing spectacle. By

this experiment it appears, that the electric virtue acts equally both within-side and without the globe, and in directions perpendicular to its surface. Hence, also, we see the power of electricity is greater by far than gravity with us.

Exp. IV. The hoop of threads remaining about the globe in motion, as in the last experiment, if the room be darkened, the ends of the threads on the outside of the globe will be all tipped with fire, and make a beautiful apparition of stars: which shews, that the electric virtue is a fine thin bluish flame of fire, much like that of phosphorus gently rubbed in the dark. The threads within exhibit no appearance of light; which shews, that this virtue acts only outwardly, and by that means the threads within are drawn towards the surface.

Exp. V. A long, pointed piece of iron being laid on a frame of silken strings, with one end about a quarter of an inch from the globe, will, at the other end, which terminates in a conical point, emit a purple flame of electrical fire, diverging each way from the point, like the rays of the sun from the focus of a burning glass in a darkened room. This pencil of electric rays is visible even in the daylight, but is extremely so in a room made dark; and if the finger be held within a quarter of an inch, it causes the fire to issue out in a greater quantity, and to appear much more luminous than before.

Exp. VI. The finger being placed as above directed, within a quarter of an inch of the said flame, will be sensible of a gentle blast of wind from the end of the iron, that is, the electrical fire will issue out of the point in such a manner, as to blow against the finger very sensibly; and if the finger be held still nearer, the large pencil of rays will be condensed in such a manner as to run out of the point upon the finger in a stream, or body, of dense yellow fire, and strike the finger like a gentle jet d'eau; and, indeed, the phenomenon may be truly called a jet de feu. This electric flame, also, is sensible to the smell, and much resembles, in that respect, the fire of phosphorus.

Exp. VII. If, while the flame continues to appear from the point of the iron, the finger be placed any where upon the iron, the flame at the end disappears immediately; if the finger be taken off, it again does instantly appear; and so by putting the finger off and on successively, the electric flame will appear and disappear alternately. The reason whereof is, that when the finger is applied, the electric virtue all runs off upon the finger, as a non-electric body, and therefore cannot go to the pointed end to produce the flame, as it does when the finger is taken off.

Exp. VIII. If a musket-barrel be suspended, and the finger applied near it, as within $\frac{1}{2}$ of an inch, the fire will forcibly issue out, and strike it, and in striking it will give a very sensible snap; and several fingers being successively applied to the

barrel, will cause several such eruptions and snapplings of the fire, which will be all very sensible to the feeling, to the eye, and to the ear; and produce a most extraordinary and entertaining phenomenon.

Exp. IX. If a chain, or hempen-cord, be suspended by silken strings, all round the room, of any length you please, and one end thereof be hung by a loop across the barrel, the electrical fire will instantly be transmitted through the whole length of the chain, and appear upon every part at the approach of the finger, and be heard to snap, and strike with as great, if not greater, force, than from the gun-barrel itself. In this particular, the electric fire seems somewhat a-kin to that of lightning.

Exp. X. If a feather be suspended by a hempen or flaxen thread, or string, it will, when held near the barrel, be strongly attracted thereby, and adhere immovably thereto; because all the electricity goes away, or runs off through the non-electric bodies, with which the said feather communicates. But the manner how the feather can be attracted by a virtue or power acting outwardly, and in contrary directions may seem somewhat strange, yet it is accounted for by the foregoing theory.

Exp. XI. The same feather, or any light body, suspended near the gun-barrel by a silken string, will be first attracted by it, and then soon afterwards repelled; and will continue to be so repelled till it has touched some other body. The reason of this is, that upon the contract with the barrel, the feather is impregnated with the electric virtue, which will not run off upon the silken string, as being an electric *per se*. Now, it is found to be the case of all attracting powers, that bodies equally possessed with them always repel each other, unless they are either in immediate contact, or very near it. But when the feather has touched some non-electric body, it loses its electricity, and again becomes capable of being attracted.

Exp. XII. If the silken string by which the feather is suspended be wetted throughout its length, it will become a non-electric body; and the feather, instead of being attracted and repelled, will now be only attracted. For all the electric virtue runs off by the moisture of the thread: by which it appears, that water, or any kind of moisture, is a non-electric substance, and so a conductor of electricity. Hence it is, that in a moist air, the feather in its repelled state will, by degrees, lose all its electricity among the aqueous particles, and will then again return to the electrified barrel, by attraction.

Exp. XIII. In like manner, a card, or tin-plate, being fitted into the end of the barrel, if any light bodies be laid thereon, as leaf-gold, silver, or brass, &c. they are immediately repelled, as if blown away with a blast of wind; nor will they come near the barrel or plate again, till they have first discharged their electricity on some non-electric bodies.—

Note,

Note, While the globe is whirling round, some person standing by must lay his finger over the barrel, to prevent the electric virtue going to the light bodies till the appointed moment; when, upon taking off the finger, they all fly off at once.

Exp. XIV. If under the said plate you hold another, with the same light bodies upon it, they will be attracted and repelled alternately between the two plates, in a very entertaining manner, and with a very great velocity, and for a considerable time. The reason why they are attracted a second, third, &c. time, is because each time they are repelled back to the lower plate, they lose upon it all their virtue and so become again attractible.

Exp. XV. If a large plummy feather be suspended horizontally at the end of a long chain, communicating with the barrel, and another set upright under it, on a cork, in a glass phial upon a pedestal; then when the finger (before laid on) is taken off the barrel, it is very pleasant to see how the electricity coming among the plumule, or fibres of the suspended feather, will cause them to extend and expand themselves every way from the rib of the feather, at the same time they will attract the feather beneath, and cause its fibres to raise themselves, and bristle out in the same manner. Here it is observable, that all the plumule repel each other, and therefore stand at an equal distance nearly; and this they do, as being all possessed of the same virtue, which cannot go off, because of the glass phial, which is an electric *per se*.

Exp. XVI. While the feathers are in their repellent state, if any one lays his finger on the barrel, or any part of the chain, it is beautiful to see how instantly the feathers are sensible of it, by letting their plumage all fall and drop into their natural state. As also if he but slightly touches the barrel, or chain, the feathers suddenly catch, and shrink in, like the sensitive plant; and hence, by the way, some think the phenomena of that plant are owing to the repulsive power of electricity between the finger and its leaves.

Exp. XVII. If, while the feathers are electrified, a person approaches his finger near them, (especially that which is suspended) they will immediately point all their plumule towards the finger, and be strongly attracted by it; and if the finger touches the feathers, they all seem eager to embrace it, and are strongly attached thereto; if the hand be moved round about the suspended feather, the feather will nimbly turn after it, and every where endeavour to lay hold on it; which, when it does, it loses all its electricity, and again becomes non-electric.

Exp. XVIII. If to a gun-barrel you adapt a small tin cup, and pour in water, then a person holding his finger perpendicular over the water, and within a quarter of an inch of its surface, or less, will find

the water rise up in form of a cone to meet his finger, and from the vertex or top thereof, a little stream of fire will issue to the finger, and snap against it as usual, though not with so much force as from the sides of the pot or the barrel itself. It is observable, that neither the water nor any other body will be in the least sensibly heated by all the electric fire they are capable of receiving. Whence it appears, that this fire is not sufficient to put the small particles of bodies into such a vibration or agitation, as to excite the least sensation of warmth or heat.

Exp. XIX. If a sponge, thorough dry, be hung on to the electrified barrel, it gives no appearance of fire, which shews it to be an electric substance: but if when the sponge has been immersed in water, it be suspended to the barrel as before, and the finger or hand be applied near to it, the fire issues out with considerable force and snapping, and the drops which before the sponge was electrified fell very slowly, will now fall very fast; if the room be darkened, these drops will appear to be drops of fire, and illuminate the basin into which they fall.

Exp. XX. If a capillary syphon be hung on to the small cup of water above-mentioned, at the end of the barrel, and the finger laid across the barrel to prevent the electric virtue going to the water; then before the water is electrified, you observe the syphon to drop only, and that very gently; but when the finger is taken off, and the water becomes electrified, the syphon runs a stream; and if the room be dark, it issues from the syphon in appearance of fire.

Exp. XXI. A person standing on a cake of rosin, with his hand laid on the gun-barrel, if a vein be opened in his arm, then (if the electricity be stopped by the finger, as above) the blood will fly out to a certain distance; but when the finger is taken off, and the person by that means electrified, the blood will receive an impetus therefrom, and spin out with a much greater velocity, and to a much greater distance than before.

Exp. XXII. If a phial of water be provided, and well corked, and a wire bent on the top be pierced through the cork, and thrust down near the bottom of the phial, leaving the upper part standing about two or three inches above the bottle, then laying this wire on the globe in motion, the wire will receive the electricity from the globe, and the water will be impregnated therewith, the more as the wire is kept longer on the globe; then the person thus holding the phial in one hand, is to approach a finger of his other hand near the middle part of the globe, and he will receive the electric eruption of fire with a very considerable snap and force, greater by much than what proceeds from the barrel alone; the reason is, because all the electricity running through the wire into the water, is there condensed as it were, and confined by the

electric substance of glass, and so acts in a greater quantity, and therefore with a greater force, than when it issues from the barrel unconfined.

Exp. XXIII. In order to make this condensation of the electric fire yet greater, the cork and top of the phial is to be closed every way very nicely with sealing-wax; and then applied to the globe, as before, when the phial of water has been fully saturated with electricity, the surplus will immediately issue out in wonderful streams of purple fire, through several pores it finds in the cork and wax; and very often many of these streams will make a beautiful appearance in the room when darkened, and is a most singular phenomenon in nature.

Exp. XXIV. If instead of water we fill the phial with quicksilver, the snap and force will be somewhat greater, but nothing near in proportion as mercury is denser than water; so that the force of electric percussion does not appear to depend upon the quantity of matter in the percussive phial, for if it did, the phial of mercury must give fourteen times a greater stroke (*cæteris paribus*) than the same sized phial of water, which it does not do, and therefore some other principle of action seems latent in the substance of bodies.

Exp. XXV. While the phial of mercury is electrifying on the globe, the electric streams will issue out of the sealing-wax more copiously than from the phial of water, and will of themselves snap; and these flashings and snappings succeed each other sometimes very fast, and represent, as it were in miniature, an artificial thundering and lightning; and their phenomenon is peculiar to the mercurial phial, the phial of water never snapping of itself that I have yet observed.

Exp. XXVI. If either the phial of water or mercury, when electrified on the globe, be hung on the gun-barrel, the hand still holding it fast, then a finger of the other hand applied near the barrel, will draw off a spark that will give a very sensible snap and stroke, which will be felt in one or both the arms, and also across the breast; and it is very remarkable, that this sensation is rather an uneasy than a painful one, and goes no farther than the elbows, in general.

Exp. XXVII. If the electrical virtue be sufficiently condensed in the phial, by holding the wire long on the globe, then the room being made dark, and the phial held up with the hand, the electric fire will be seen to go off from the point of the wire in a small white flame, which will continue some time; and if a finger be applied near it, the wire will emit it with a snap, but not so forcibly as when held on the globe. And this is the only way, perhaps, of retaining the electric fire, or making its action temporary. And the letter from Paris says, it has been thus retained in the frost for thirty-six hours together. But I cannot produce any permanency of its efficacy like that.

Exp. XXVIII. A person standing on a cake of rosin, at least three inches thick, laying one hand on the gun-barrel, will be electrified, that is, he will be all over possessed with the electric virtue, and at the same time feel nothing of it, unless some person standing by put his finger near to any part, and then the virtue will be emitted in form of fire from any part, and snap, and become very sensible to both the parties, but in a very innocent manner.

Exp. XXIX. If the person electrified holds in his hand a sword, or any pointed polished piece of iron, and the room be darkened, a continual flame issues out of the point every way, like that described in Exp. V. and VI.

Exp. XXX. If the electrified person holds a small cup of water in one hand as he stands on the rosin, and with the other takes hold of the wire in the electrified phial, and then the person who holds the phial, by approaching his finger near the surface of the water, will cause it to emit the fire with a more sensible snap and force, than can be excited without it.

Exp. XXXI. If the person standing on the rosin holds a piece of money between his teeth, and the wire of the electrified phial with one hand; then if the person who holds the phial touches the money, the shock will be very sensibly felt in the teeth and head of the electrified person who holds it, and also to the other who touches it.

Exp. XXXII. Let a person stand on one cake of rosin, and lay one hand on the barrel; and let another person stand on another cake by him, and then when the first person is thoroughly electrified, let them both incline their heads and salute each other, and the fire will join their lips when nearly touching, and give them a smart and mutual rebuff, which will make them separate more hastily than they joined; but yet the pungency is not so great as to be very disagreeable.

Exp. XXXIII. A wire fixed on a pedestal, and placed upright in a basin of water, is to be electrified from the phial above-mentioned, and then the person holding the phial is to touch the surface of the water in the basin with the other hand; the fire here has a considerable effect, but not so great as the letter from Paris seems to intimate at, least I could never find it so.

Exp. XXXIV. The phial being electrified, as above, the whole company join hands, or communicate with each other by wires, then the operator, or person who stands first, at one extremity of the line, hangs the electrified phial on the barrel, when the person at the other extremity draws off the spark from the barrel; and at that instant all the company receive the shock, which they feel to their elbows, and in both their arms. But I could never yet find those shocks so violent and dangerous as they have been represented, though they are nearly as great as any person (especially the men) care to endure.

endure. This experiment will equally succeed, be the company ever so large.

Exp. XXXV. A person standing on rosin, with one hand on the barrel, points the finger of the other to the warm spirits of wine, and by communicating the electric fire thereto, kindles the rising fume, and so sets the whole on fire. In this manner, any sort of matter, which, when warmed, will send forth an inflammable vapour, may be thus set on fire.

Exp. XXXVI. Another way to set fire to the spirit is this; the person holds the phial of mercury, or water, when electrified, on the barrel with one hand, and the warm spirit being put into a cup or spoon adapted to the barrel, and thereby strongly electrified, a finger of the other hand being held over and near the spirit, draws the electric spark out of it, and with a snap sets the vapour in a flame, and consequently all the spirit.

Exp. XXXVII. Because gunpowder, when heated, emits no inflammable stream, it cannot be fired by itself; but if you mix with it a little inflammable vegetable oil of any sort, and grind them together, and then put a small quantity into a spoon and heat it, the vapour will be fired in each of the two ways above-mentioned for firing the spirit, and will set fire to the oil and powder nearly at the same time, and the powder will be exploded in the same manner it usually is when wetted. But it may be fired dry, by mixing it with camphor, and reducing both to a powder, for this will send forth an inflammable vapour, which will be kindled when heated, in either of the methods above described.

Exp. XXXVIII. If a plate of tin be adapted to the end of the barrel, and another be held about two inches under it with a square or long piece of leaf gold, brass, &c. then while the barrel is electrified, the said piece of gold will be swiftly at first attracted and repelled between the two plates, till at last the action between each becoming equal, the leaf gold will be so equally affected by either, that all its variable motion will be destroyed, and it will appear to be suspended at rest between both, and afford a most surprising and agreeable spectacle.

Exp. XXXIX. If a small bell of a clock be fixed to the end of the gun-barrel, and another at four inches distance on a pedestal of wood at the same height, and then a small ivory ball be suspended by silken strings in the middle between both; the barrel when electrified will electrify the first bell, and that will attract the ivory ball; as it hangs by silk, which is itself electrical, it will retain all the electric virtue it receives from the bell, and therefore will be repelled from it, and thus be made to strike against the other bell; on this it will discharge all its electricity by contact, and so become again a non-electric, and in that case will be again attracted by the first bell. And this effect will be produced alternately, so long as the globe is in motion; the

consequence of which is, that the ivory ball will be put into constant vibration, and make an electrical pendulum, which, as it strikes each bell, it makes them ring, and produce one of the most agreeable effects both to the eye and ear.

Exp. XL. If a small plate be held under that adapted to the gun-barrel, and light bodies laid upon it, and then a fine piece of muslin or lawn be interposed between both; the electrified barrel will not affect the light bodies, but they will remain absolutely at rest. For the electric virtue will run off upon the muslin, and its supporter, as being non-electric bodies; and so will not come near the light bodies to put them in motion.

Exp. XLI. If a loadstone, armed with iron, be hung on to the gun-barrel by an iron wire, the electric virtue will rush out from every part, but more forcibly from the iron than from the stone itself; from the stone it seems to be emitted in a more lax manner, and diffused in a sort of steam or fiery vapour; whereas from the iron it issues in a more impetuous, dense, and penetrating stream. By this experiment we see the two most considerable powers of nature, electricity and magnetism, do no way interfere, or impede each other's action.

Exp. XLII. If the globe be exhausted of all its air, and then whirled about on the machine, the electricity will be observed to act wholly within the globe, where it will appear (in a darkened room) in form of a cloud or flame of reddish or purple coloured light, filling the whole capacity of the globe. This voluble flame will be diminished, and disappear by degrees as the air is gradually admitted into the globe. The reason why the action of the electric virtue does not shew itself outwardly, is the strong repulsive power of the electric particles of air encompassing the globe, confining the electric effluvia, and causing it to tend inwards, where it meets with no resistance in the vacuum sphere.

In plates XLVI. and XLVII. there is given a view of several electrical machines, which have been invented by different persons who have been curious in trying electrical experiments.

ELECTROMETER, an instrument contrived to measure the force of electricity.

This instrument was contrived about the year 1748 by M. Le Roy and M. D'Arcy, and is made in the following manner.

In Plate XLVII. fig. 1. A B is a large vessel containing a glass bottle CD, called the philosophical egg: at the extremity of the neck of this bottle is fitted on the root V, perfectly cylindrical, one line in diameter, and twelve inches long. The vessel A B is covered again at the top with a plate of brass H, which fits close upon it; this plate has a large perforation at its center, and so has the vessel, that the rod may pass through at liberty. At the upper extremity of the rod, is the small circular plate of brass L, fourteen lines $\frac{1}{2}$ diameter. The vessel A B being

being full of water, the egg is immersed to a certain depth, which ought to be such that, the instrument being at rest, that is, not electrified, the lower extremity of the egg may be, as near as possible, to the bottom of the vessel without touching it. That the egg and rod may always be in a vertical situation, the egg is ballasted with mercury, by which means the center of gravity being very low, the whole keeps itself perpendicular to the horizon, and proves by the least possible motion of the egg, from its balance, that, if it were not confined, it would go towards the side of the vessels, and swim sometimes on one side, and sometimes on the other; wherefore it was necessary to determine it to a center, in the following manner: on the plate H are fixed five silver wires in the form of a cross, like those in micrometers; this cross is formed by double wires which have a small square space in the center of the plate, which, being larger than the diameter of the rod, permits it to ascend and descend between the wires without any sensible friction, and yet restrains it from erring from its center: and this singular phenomenon arises, when the whole machine is strongly electrified; the rod keeps in the middle of the wires, and almost without touching them, because, being electrified, as well as they are, it avoids them continually.

After this description of the instrument, it is easy to conceive its use, especially if we attend to this known principle in hydrostatics, that a body immersed in water swims on the surface, or sinks in it, in proportion as a volume of water, like that it possesses, is lighter or heavier than the body itself; from this principle it follows, that a volume of water equal to that of the egg, and that part of the rod immersed in the water, when the whole is at rest, was equal to the egg, the little plate, and all the rod: consequently, if the whole be elevated one inch, the power which will sustain it at this height, will sustain a weight equal to a volume of water of the thickness of the rod and an inch above; because the volume of water which the egg and rod then possesses is lessened by this quantity. If, therefore, different powers suspend it at 1, 2, 3, 4 inches, &c. in height above the point of rest, these powers will be, with regard to each other, as these numbers, double, triple, quadruple, &c. you will see, in a moment, that electricity produces the same effect upon the electrometer, that is, it performs the function of a power which would suspend it at 1, 2, 3, 4 inches, &c. above its point of rest, and consequently, that by means of this instrument, we may estimate all its different degrees of force; let us suppose, for example, the whole machine composed of the vessel A B, the egg, &c. placed like that in O, (fig. 2.) on a recipient of glass, or any other electric *per se*. Electrify the vessel A B, the rod V and plate L will become electrified also. Now, it is admitted, that all electrical bodies repel each other;

thus the little plate L and the rod V, being repelled by the great plate H, will necessarily rise more or less in proportion to the strength or weakness of the electricity. Electricity therefore will, as I have said before, perform the function of a power, that will suspend the instrument to a certain elevation; but, as these powers are proportional to the elevations of the instrument above its equilibrium, or point of rest, these elevations also will be in proportion to the different degrees of the force of electricity: this is therefore a true electrometer. But this instrument is of much more extensive use than barely this; for it may be employed in a great number of electrical experiments, to determine the laws of attraction, repulsion, transimission, &c. in electrical bodies; discoveries equally important with that of mensurating the electrical force.

Method of using the electrometer.—As electrical bodies have this inconvenience, that they cannot be approached, without destroying their electricity, it is evident, that, if we come so near the electrometer as to judge of its motions with exactness, we should destroy its electricity. This reason determined us, after a number of attempts, to make our observations in the following manner: we placed a great lantern, with a large wax candle, in a part of the room, which projects its light through a hole on the electrometers I K (we have not drawn the lantern in the plate, for fear it might have caused some confusion, and have, therefore, only exhibited the stream of light); behind these electrometers is a very solid frame Q; all the part X is wood, but it may be of any opaque matter. In this frame are cut two rectangles, or windows, filled with glasses, on which are marked very exact divisions in strong Indian ink.

This frame is so disposed, that the projection of the electrometers may fall upon the glasses, and the extremity of the rod D, being made in the form of a cone, projects a very nice shadow. Now, as these glasses are transparent, the observer, placed behind in F, sees, in the most distinct manner, all the different elevations of the electrometer, and can therefore judge of all its variations with the utmost exactness; for, the plane of the square being perpendicular to the horizon, and the electrometer rising and falling in a parallel plane, the elevations and depressions of the shadows are always correspondent to those of the electrometers. The chains M serve to conduct the electricity from the bar of iron, or any other electrified body, to the electrometer; the square Q, instead of two windows, may have but one, that being sufficient for the electrometer. But we must, at the same time, make our observations on the instrument with which we made the experiments, and the electrometer too, to be assured that the electricity is always equal; which cannot be done without comparing their shadows very closely. The construction of the electrometer

thews

shews it has all the essentials to an instrument of this kind.

1st, As the electrical force is very weak, the instrument must be very nice, and sensible of the least impression; therefore the weight of eight grains, laid on the little plate, makes it sink above four inches.

2dly, As the electrical force is very subject to alterations, the instrument must be so contrived as to exhibit all its variations; a thousand experiments have convinced us, that the least alteration in the force of electricity immediately affects the electrometer. It is, in short, universal, for the true electrometer is the cylindrical rod V, which determines the quantity of electrical power by the number of its parts raised above the point of rest. Now it is not difficult to procure a cylindrical rod of a line diameter. It is true, the diameter of the little plate L, and its distance to H, the point of rest, may cause some differences in the repulsions; but it is easy to observe all these proportions; so that any one may construct an electrometer, which will be operated upon, like ours, by the same power of electricity. This property seems, to me, one of the most remarkable in our instrument, like that of M. Reaumur's thermometer, which all Europe has admired. As I have said our electrometer might be used as an instrument, it may be proper to give some account of the experiments we have made. In order to discover whether electricity is in proportion to the bulk or surface of bodies, we applied ourselves in the manner following: The instrument E served for an electrometer, the other, I, was designed to make the experiment on. Above this last was suspended perpendicularly, at the distance of ten inches, a cap or portion of the sphere PS; this cap was of hammered iron, very thin and of a very regular figure; it received its electricity from the electrical bar by a brass wire, and, being suspended on silk, preserved it. The chain in *fig. 2*, which has a communication with both instruments; in this experiment but with the electrometer; so that the instrument was not electrified. One person made his observation on the square of the height of the electrometer caused by the electricity; another observed the elevation of the instrument; and several repeated experiments confirmed us in the opinion, that the elevation of the instrument was in proportion to the force of the electricity; and this we found to answer exactly, after having repeated the experiment above fifty times. We afterwards poured mercury into this cap, till it increased the weight sixty-fold, and found no sensible alteration in the experiment. This seems to shew, that the attraction of electrical bodies is in proportion to their surfaces; but this is a matter of doubt, for the fire and sparks drawn from an electrical body may follow some other law. Certain it is, that a piece of any metal must be of a certain thickness to extract

shining sparks from it, otherwise you can only procure such a kind of fire as is extracted from electrified wood of any thickness; yet, if we extract sparks from the middle of a plate of iron, they are very strong, and those extracted from the cap, whether with or without mercury, seemed to have no difference. We have, in short, found, by a multitude of experiments, that the ponderosity or lightness of a body neither increases nor diminishes its electricity.

ELECTRUM, amber, in natural history. See the article **AMBER**.

ELECTUARY, in pharmacy, a form in which both official and extemporaneous medicines are frequently made. It may be considered as a number of boluses united together, but made a little softer by the addition of a due proportion of syrups, &c.

ELEGANCE, or **ELEGANCY**, an ornament of politeness and agreeableness, shewn in any discourse, with such a choice of rich and happy expressions, as to rise politely above the common manners, so as to strike people of a delicate taste, and diffuse a relish which affects every body.

It is observed that elegance, though irregular, is preferable to regularity without elegance: that is, by being too scrupulous of grammatical construction, we lose certain licenses wherein the elegance of language consists.

ELEGANCE, in painting, a certain manner which embellishes and heightens objects, either as to their form, colour, or both, without destroying or perverting the truth. It is not seen in the correctness of the design, as appears from Raphael, and the antique. It is most sensibly perceived in works otherwise careless and inaccurate, as in Corregio, where, notwithstanding all the defects as to justness of design, there is an elegance even in the manner of the design itself, as well as in the turn of the attitudes, &c.

ELEGIT, in law, a writ of execution, which lies for a person who has recovered debt or damages; or upon a recognizance in any court, against a defendant that is not able to satisfy the same in his goods.

ELEGY, in poetry, primarily and generally implies a mournful poem.

The word is derived, according to Didymus, from ϵ , a particle of grief, and $\lambda\epsilon\gamma\omega$, to say, and according to others from $\epsilon\lambda\epsilon\gamma\omega$, something moving, and $\lambda\epsilon\gamma\omega$.

As elegy, at its first institution, was intended for tears, it expressed no other sentiments, it breathed no other accents, but those of sorrow. With the negligence natural to affliction, it sought less to please than to move. By degrees, however, elegy degenerated from its original intention, and was employed upon all sorts of subjects, gay or sad, and especially upon love.

Ovid's books of love, the poems of Tibullus and
D d Pro.

Propertius, are intitled elegies; and yet so far are they from being sad, that they are sometimes scarce serious: so that one and the same title was indiscriminately given to poems on different subjects, but which agreed in their verse and manner of writing. The chief subject then to which elegy owes its rise, are death and love: so that elegy ought to be esteemed the most perfect, which has somewhat of both at once; namely, where the poet bewails the loss of some youth, or damsel, falling a martyr to love. The next are those elegies full of that melancholy complaint which lovers seldom want matter for: the thoughts of elegy should be always natural, far from the affectation of wit: its sentiments tender and delicate; its expression simple and easy, always retaining that alternate inequality of measure which Ovid extols so much; and which gives the elegiac poetry of the ancients so much the advantage over the moderns. Elegy should flow in one even current, smooth, humble, and unaffected; and yet she is not abject in her humility, but becoming, elegant, and attractive.

Some early writers in this way, among the Greeks, were Callimachus, Philetas, Mimnermus, Callinus, and others, of whose writings only fragments have been saved. Quintilian gives the preference to Callimachus; but Horace ranks Mimnermus above him. Mimnermus is by some reckoned the inventor of elegiac verse; he at least gave it its perfection, and was perhaps the first who transferred it from funerals to love.

Among the Latins, Ovid, Tibullus, and Propertius, bear the first rank: there is scarce anything of Catullus's elegiac, except the measure of some of his verses; and those so rough, that they cannot be read without great offence to the ear. Ovid is generally reckoned the first among the elegiac writers; yet Tibullus is less diffuse and more correct. Ovid's perpetual repetition of *mei, tui, and sui*, in the last foot of his pentameters, is unpardonable. Tibullus and Propertius rarely fall into this fault; but into another, especially the latter, from which Ovid is free; and that is, concluding the pentameter with words of three or four syllables; whereas harmony requires a word of no more than two.

Among the ancients, hexameters and pentameters were so peculiar to elegy, that this kind of metre is usually styled elegiac. Instead of it, we, in our tongue, use the word heroic.

Among our modern poems, we have only some elegies on funeral occasions; but we have many that may be called so in the larger sense of the word, as used by the ancients; many very ingenious ones on love; and others of a melancholy and soft turn.

ELEMENT, in physiology, a term used by philosophers to denote the original component parts of bodies, or those into which they are ultimately resolvable.

The elements of Aristotle were four, earth, water, air, and fire. See ARISTOTELIAN *Philosophy*.

The Cartesians admit only three elements, the first a *materia subtilis*, or fine dust; the second, a coarser, but round kind; and the third, a still more irregular and hooked kind of particles. See the article *CARTESIAN Philosophy*.

Concerning the true elements of nature, the incomparable Sir Isaac Newton thus explains himself in his optics: "It seems probable to me, that God in the beginning formed matter in solid, massy, hard, impenetrable, moveable particles, of such signs and figures, and with such other properties, and in such proportion to space, as most conduced to the end for which he formed them; and that these particles, being solid, are incomparably harder than any porous bodies compounded of them; even so very hard, as never to wear or break in pieces, no ordinary power being able to divide what God himself made one in the first creation. While the particles continue entire, they may compose bodies of one and the same nature and texture in all ages: but, should they wear away, or break in pieces, the nature of things depending on them would be changed. Water and earth composed of old worn particles, and fragments of particles, would not be of the same nature and texture, now, with water and earth composed of entire particles in the beginning: and therefore, that nature may be lasting, the changes of corporeal things are to be placed only in the various separations and new associations and motions of these permanent particles; compounded bodies being apt to break, not in the midst of solid particles, but where those particles are laid together, and only touch in a few points."

The chemical elements or principles to which all bodies may be ultimately reduced, are these five: 1. Water, or phlegm, which, in the chemical analysis of them, rises first in form of vapour. 2. Air, which escapes unseen in great quantities from all bodies, so as to constitute half the substance of some of them. 3. Oil, which rises after, and appears swimming on, the surface of the water. 4. Salt, which is either volatile, or rises in the still, as that of animal substances; or fixed, as that of vegetables, which is obtained by reducing them to ashes, making a lixivium or ley of these, and afterwards evaporating the moisture; by which means the common salt shoots into crystals. 5. Earth, or what is called *caput mortuum*, being what remains of the ashes after the salt is extracted. This is the last element of all bodies, which can be no farther altered by any art whatsoever. See WATER, AIR, &c.

ELEMENT, in a figurative sense, is used for the principles and foundations of any art or science, as Euclid's Elements, &c.

ELEMI, or ELEMY, is a resin of Asiatic origin: the plant which produces it is not yet known with certainty. There is also an inferior kind, brought from America, which is the only one now to be met with in the shops: the parent of this sort is called

called by Ray, *Arbor Brasiliensis gummi elemi simile fundens*, &c. a Brazilian tree, yielding a gum like elemi, with winged leaves, verticillate flowers, and a fruit about the size and shape of an olive.

The true elemi comes over in large oblong masses or round leaves, generally wrapt up in leaves of the Indian reed. It is of a yellowish or rather greenish white colour, semitransparent; of a soft consistence, betwixt that of wax and turpentine, or dry on the outside and softish within: by age, it grows hard and brittle throughout. It has a moderately strong, not unpleasant smell, resembling that of a mixture of fennel, daucus, and smallage-seeds. It is commonly full of impurities, which are obvious enough to the eye.

This resin has hitherto been employed only in external applications; in nervine, vulnerary, and digestive plasters and balsams. In making these kinds of compositions, we must be careful to avoid too great a degree of heat in mixing the ingredients; lest the essential oil, the most useful part of the elemi, be lost.

ELENCHUS, in logic, a sophism, or fallacious argument, which deceives the hearer under the appearance of truth. See the article SOPHISM.

ELEOSACCHARUM, or ELÆOSACCHARUM. See the article ELÆOSACCHARUM.

ELEPHANT, *Elephas*, in zoology, a genus of quadrupeds, of the order of the jumenta, the characters of which, according to Linneus, are these: it has no fore-teeth, the upper canine, or dog teeth, are considerable long, it has a very long flexible proboscis or trunk, and two paps placed on the breast.

The teeth of this animal is what we call ivory. See IVORY.

The elephant, of which there is only one known species, is, when full grown, from seventeen to twenty feet high; and its body is withal so enormously bulky, that the belly reaches nearer the ground than could easily be conceived of a creature of its height. The trunk is, properly speaking, nothing but the nose continued to a great length; its substance is fleshy, but firm, being composed of three series or orders of fibres: this trunk the creature can contract or protrude forward with great violence, from the length of one foot to five or more.

Knights of the ELEPHANT, an order of knighthood in Denmark, conferred upon none but persons of the first quality and merit. It is also called the order of St. Mary. Its institution is said to have been owing to a gentleman among the Danish croisées having killed an elephant, in an expedition against the Saracens, in 1184, in memory of which king Canutus instituted this order, the badge of which is a towered elephant, with an image of the Holy Virgin encircled with rays, and hung on a watered sky-coloured ribbon, like the George in England.

ELEPHANTIASIS, or ELEPHAS, in medicine, is a species of leprosy, so called, because it effects the legs in such a manner, as to make them appear like those of an elephant. See LEPROSY.

The word is derived from the Greek, *ελεphas*, an elephant.

ELEPHANTOPUS, in botany, a genus of plants, whose flower is compound and tubulose, and consists of four or five hermaphrodite ligulated corollulæ, each having a narrow border divided into five parts; the stamina are five very short capillary filaments, top'd with tubulose cylindrical atheræ; the seeds are solitary, and contained in the cup of a compressed figure, and crowned with bristly hairs.

ELEVATION, *Elevatio*, the same with altitude or height. See ALTITUDE.

Angle of ELEVATION, in gunnery, that comprehended between the horizon and the line of direction of a canon or mortar; or it is that which the chase of a piece, or the axis of its hollow cylinder, makes with the plane of the horizon.

ELEVATION, in architecture, the same with an orthographic, or upright draught of a building. See ORTHOGRAPHY.

ELEVATION of the *Host*, in the church of Rome, that part of the mass where the priest raises the host above his head for the people to adore.

ELEVATOR, in anatomy, the name of several muscles, so called from their serving to raise the parts of the body to which they belong; such are the elevator alæ nasæ, the elevator of the auricle or external ear, the elevator of the epiglottis, of the eye-lids, humerus, lips, urethra, and those of the anus, called also levatores. See MUSCLE.

The elevator of the eye-lids is also called *superbus*, as being used when people put on a haughty high look.

ELEVATOR, in surgery, an instrument to elevate or raise bones, as in fractures of the skull, &c.

ELEVE, a French term, sometimes met with in the English language, signifying a disciple or scholar.

ELEUSINIA, in Grecian antiquity, a festival kept in honour of Ceres, every fourth, by some states, but by others, every fifth year. The Athenians celebrated it at Eleusis, a town of Attica, whence the name.

ELEUTHERIA, another festival celebrated at Plataea, by delegates from almost all the cities of Greece, in honour of Jupiter Eleutherius, or the assertor of liberty.

ELIQUATION, in metallurgy, a separation of the different parts of mixed bodies, by the different degrees of fire required to melt them.

ELIRE, or CONGE D'ELIRE. See the article CONGE.

ELISIUM, or ELYSIUM. See ELYSIUM.

ELISION, in grammar, the cutting off or suppressing a vowel at the end of a word, for the sake of

of sound, or measure, the next word beginning with a vowel.

Elisions are pretty frequently met with in English poetry, but more frequently in Latin, French, &c. They chiefly consist in suppressions of the *a*, *e*, and *i*, though an elision suppresses any of the other vowels: in the following example from Virgil there are three elisions.

Phyllida amo ante alias. —

ELIXATION, in pharmacy, the extracting the virtues of ingredients by boiling or stewing. See **DECOCTION**.

ELIXIR, a compound tincture extracted from many efficacious ingredients. Hence the difference between a tincture and an elixir seems to consist in this, that a tincture is drawn from the ingredients, sometimes, with an addition of another to open it, and dispose it to yield to the menstruum; whereas an elixir is a tincture extracted from several ingredients at the same time.

The word is Arabic, *al-ecfir*, or *al-ekfir*, and implies an artificial extraction of some essence.

ELK, *Alce*, in zoology, an animal of the deer-kind, with the horns palmated, and without a stem. It is a native of the northern parts of Europe; and is a very large and strong animal, being equal in size to a horse, but much less beautiful.

Elks hoofs stand recommended for the cure of the epilepsy; but at present are only used as an ingredient in some old compositions.

ELL, *Ulna*, a measure of length different in different countries; but those mostly used in England, are the English and Flemish ells: the former of which is three feet nine inches, or one yard and a quarter, and the latter only twenty-seven inches, or three quarters of a yard. In Scotland, the ell contains $37\frac{2}{3}$ English inches. See the article **MEASURE**.

ELLIPSIS, in geometry, a curve line returning into itself, and produced from the section of a cone by a plane cutting both its sides, but not parallel to the base. See **CONIC SECTIONS**.

The easiest way of describing this curve, in plano, when the transverse and conjugate axes *AB*, *ED*; (Plate XLVIII. fig. 1.) are given, is thus: First take the points *F*, *f*, in the transverse axis *AB*, so that the distances, *CF*, *Cf*, from the center *C*, be each equal to $\sqrt{AC - CD}$; or, that the lines *FD*, *fD*, be equal to *AC*. Then, having fixed two pins in the points *F*, *f*, which are called the foci of the ellipsis, take a thread equal in length to the transverse axis *AB*; and fastening its two ends, one to the pin *F*, and the other to *f*, with another pin *M* stretch the thread tight: then if this pin *M* be moved round till it returns to the place from whence it first set out, keeping the thread always extended so as to form the triangle *FMf*, it will describe an ellipsis, whose axes are *AB*, *DE*.

The greater axis, *AB*, passing through the two foci *Ff*, is called the transverse axis; and the lesser one *DE*, is called the conjugate, or second axis: these two always bisect each other at right angles, and the center of the ellipsis is the point *C*, where they intersect. Any right line passing through the center, and terminated by the curve of the ellipsis on each side, is called a diameter; and two diameters, which naturally bisect all the parallels to each other, bounded by the ellipsis, are called conjugate diameters. Any right line, not passing through the center, but terminated by the ellipsis, and bisected by a diameter, is called the ordinate, or ordinate applicable, to that diameter. And a third proportional to two conjugate diameters, is called the latus rectum, or parameter of that diameter which is the first of the three proportionals.

The reason of the name is this: let *BA*, *ED*, be any two conjugate diameters of an ellipsis (fig. 2, where they are the two axes) at the end *A*, of the diameter *AB*, raise the perpendicular *AF*, equal to the latus rectum, or parameter, being a third proportional to *AB*, *ED*, and draw the right-line *BF*: then if any point *P* be taken in *BA*, and an ordinate *PM* be drawn, cutting *BF* in *N*, the rectangle under the absciss *AP*, and the line *PN* will be equal to the square of the ordinate *PM*. Hence drawing *NO* parallel to *AB*, it appears that this rectangle, or the square of the ordinate, is less than that under the absciss *AP*, and the parameter *AF*, by the rectangle under *AP* and *OF*, or *NO* and *OF*; on account of which deficiency, Apollonius first gave this curve the name of an ellipsis, from ελλειπειν, to be deficient.

In every ellipsis, as *AEBD* (fig. 2.) the squares of the semi-ordinates *MP*, *mp*, are as the rectangles under the segments of the transverse axis *AP* $\times$ *PB*, *Ap* $\times$ *pB*, made by these ordinates respectively; which holds equally true of the circle, where the figures of the ordinates are equal to such rectangles, as being mean proportionals between the segments of the diameter. In the same manner, the ordinates to any diameter whatever, are as the rectangles under the segments of that diameter.

As to the other principal properties of the ellipsis, they may be reduced to the following propositions: 1. If from any point *M* in an ellipsis, two right lines, *MF*, *Mf*, (fig. 1.) be drawn to the foci *F*, *f*, the sum of these two lines will be equal to the transverse axis *AB*. This is evident from the manner of describing an ellipsis. 2. The square of half the lesser axis is equal to the rectangle under the segments of the greater axis, contained between the foci and its vertices; that is, $DC^2 = AF \times FB = Af + fB$. 3. Every diameter is bisected in the center *C*. 4. The transverse axis is the greatest, and the conjugate axis the least, of all diameters. 5. Two diameters, one of which is parallel to the tangent in the vertex of the other, are conjugate diameters;

ameters; and *vice versa*, a right line drawn through the vertex of any diameter parallel to its conjugate diameter, touches the ellipsis in that vertex. 6. If four tangents be drawn through the vertices of two conjugate diameters, the parallelogram contained under them will be equal to the parallelogram contained under tangents drawn through the vertices of any other two conjugate diameters. 7. If a right line, touching an ellipsis, meet two conjugate diameters produced, the rectangle under the segments of the tangent, between the point of contact and these diameters, will be equal to the square of the semi-diameter, which is conjugate to that passing through the point of contact. 8. In every ellipsis, the sum of the squares of any two conjugate diameters, is equal to the sum of the squares of the two axes. 9. In every ellipsis, the angles FGI, fGH, (*ibid.* n° 1.) made by the tangent HI, and the lines FG, fG, drawn from the foci to the point of contact, are equal to each other. 10. The area of an ellipsis is to the area of a circumscribed circle, as the lesser axis is to the greater; and *vice versa*, with respect to an inscribed circle; so that it is a mean proportional between two circles, having the transverse and conjugate axes for their diameters. This holds equally true of all the other corresponding parts belonging to an ellipsis.

The curve of any ellipsis may be obtained by the following series: Suppose the semi-transverse axis CB= a , the semi-conjugate axis CD= c , and the semi-ordinate $=a$; then the length of the curve $MB=a+\frac{a^2}{6c^2}+\frac{4a^2c^2a^2-r^2a^2}{40c^4}+\frac{8c^4r^2a^2+r^6a^2}{112c^6}$
 $=4c^2r^5a^7$, &c. And, if the species of the ellip-

sis be determined, this series will be more simple: for if $c=2r$, then $MB=a+\frac{a^3}{96r^2}+\frac{3a^5}{2048r^4}+\frac{113a^7}{45872a^6}+\frac{2419a^9}{754972r^8}$, &c. This series will serve for an hyperbola, by making the even parts of all the terms affirmative, and the third, fifth, seventh, &c. terms negative.

The periphery of an ellipsis, according to Mr. Simpson, is to that of a circle, whose diameter is equal to the transverse axis of the ellipsis, as $\frac{d}{1}-\frac{2.2}{2.2.4.4}+\frac{3.3.5}{2.2.4.4.6.6}-\frac{2.3.5.5.7}{2.2.4.4.6.6.8.8}d^4$, &c. where d is equal to the difference of the squares of the axis applied to the square of the transverse axis.

Those who desire to be more particularly informed concerning the properties of the ellipsis, may consult Simpson's Conic Sections, and Wolfius's Elements of Mathematics, tom. 1. also Maclaurin's Fluxions, art. 609. seq. and the marquis de l'Hospital's Sect. in Gram. lib. 6.

ELLIPTIS, in grammar and rhetoric, is a figura-

tive way of speaking, by which some word in a discourse is retrenched, or omitted, when some violent passion will not let a person utter what he thinks.

ELLIPTIC, or ELLIPTICAL, something belonging to an ellipsis. See ELLIPSIS.

ELLIPTICAL ARCH, a part or segment of the curve of an ellipsis.

Elliptical arches are frequently preferred to those that are circular, in various kinds of buildings, because their span may be equal to those of the circle, without rising to so great a height; and this is the reason why they have been preferred in bridges: but it must be remembered, that they will decrease in strength, in proportion as they deviate from the circle. See the article BRIDGE.

ELLIPTOIDES, in geometry, a name used by some to denote infinite ellipses, defined by the equation $ay^m+x^n=bx^m(a-x^n)$.

There are several species of ellipsoides; as for instance, if $ay^3=bx^2(a-x)$ it is a cubical ellipsoid; and if $ay^2=bx^2(a-x^2)$ it denotes a biquadratic ellipsoid, which is an ellipsis of the third order, with respect to the Apollonian ellipsis.

ELM, *Ulmus*, in botany, a genus of trees, whose flower is destitute of a corolla; but consists of a monophyllous, rough, turbinate cup, cut at the limb into five parts, coloured within, erect, and persistent. The stamina are five subulate filaments, double the length of the calyx, topped with short erect anthers, having four furrows.

The fruit is a roundish, compressed, membranaceous drupe, including a seed of the same shape.

The flowers of the common elm come out in March upon the slender twigs of the tree before the leaves, and stand in clusters. The root is thick, hard, and woody, and sends forth a number of fibres which spread to a great distance. The trunk or body, when old, is of a dark colour, and full of longitudinal wrinkles; but the young branches are smooth and tough. The leaves are wrinkled, rough, and doubly serrated on their edges. Their base is unequal, about three inches long, and two broad, of a dark green colour, and stand on short pedicels.

This tree grows in plenty all over England: and its timber is of very great use for divers purposes, as for keels of ships, coffins, water-pipes, mill-works, knaves for wheels, handles for saws, &c. The cleanness of its grain makes it also fit for all kinds of carved-work and ornaments relating to architecture.

There are several species of elm, such as the witch-hazel, or broad-leaved elm; the smooth leaved or witch elm, and several varieties with variegated leaves, which are noticed by the curious in plants. They all delight in one and the same soil, which should be a good loam to have them in the greatest perfection; not but they will do in other lands.

These trees are increased by layers or suckers. The layers are to be preferred, as they generally arise with a better root: for if they are not well rooted when planted, they make very little progress in their growth, and frequently fail, notwithstanding, to appearance, they may have made tolerable shoots for the first two or three years; therefore we would advise those who plant elms to observe they are well rooted, as otherwise they may be deceived in their expectations.

Elms were formerly, when clipping was more in fashion than at present, much in use for hedges, and no plants are more proper where it is required to break the violence of the winds; but they should not be planted too near walls where fruit-trees are placed against, as they will by the extension of their roots, which spread to a greater distance than is commonly imagined, deprive the other plants of the nourishment requisite for their welfare. In the park elms are delightful, being planted in avenues where their noble shade and verdure demonstrates their grandeur, an example of which may be seen in Greenwich-park, whose delightful walks, so much resorted to, are chiefly adorned with these beautiful and advantageous trees.

In planting elms, it is necessary to observe, that they should not be planted too deep, particularly in loamy or clayey lands, in which latter case it is not amiss to plant them on a little hill, when there will be the less danger of their succeeding; and likewise, if they are designed for timber, not to top the extreme part of the plant, as it impedes their growth, and occasions their decaying soon.

With regard to their medicinal virtues, the leaves are astringent; and the bark good for allaying the pains of the gout, by a decoction of it reduced to the consistence of a syrup, and a third part of brandy added, and used as a liniment. It also makes a good gargarism for sore mouths, when occasioned by heat and sharpness of humours.

ELOCUTION, in rhetoric, the adapting words and sentences to the things or sentiments to be expressed. It consists in elegance, composition, and dignity. The first, comprehending the purity and perspicuity of a language, is the foundation of elocution. The second ranges the words in proper order; and the last adds the ornaments of tropes and figures to give strength and dignity to the whole. See **STYLE**, **PERIOD**, **FIGURE**, &c.

ELOGY, *Elogium*, a praise or panegyric bestowed on any person or thing, in consideration of its merit. The beauty of elogy consists in an expressive brevity. Elogiums should not have so much as one epithet, properly so called, nor two words synonymous. They should strictly adhere to truth; for extravagant and improbable elogies, rather lessen the character of the person or thing they would extol.

ELOHA, in Scripture, the singular of Elohi, one of the names of God.

ELOHI, **ELOI**, or **ELOHIM**, in Scripture, one of the names of God. But it is to be observed, that angels, princes, great men, judges, and even false gods, are sometimes called by this name. The sequel of the discourse is what assists us in judging rightly concerning the true meaning of this word. It is the same as Eloha, one being the singular, and the other the plural. However, Elohim is often construed in the singular number, particularly when the true God is spoken of; but when false gods are spoken of, it is construed rather in the plural.

ELONGATION, in astronomy, is the removal of a planet to the farthest distance it can be from the sun, as it appears to an eye placed on the earth.

The word is Latin, from *elongo*, to be distant from.

The utmost elongation of Venus can be but 45 degrees, and that of Mercury but 30 degrees; which is the reason this planet is so rarely seen.

ELOPEMENT, in law, is where a married woman departs from her husband, and cohabits with an adulterer; in which case the husband is not obliged to allow her any alimony out of his estate, nor is he chargeable for necessaries for her of any kind. However, the bare advertising a wife in the Gazette, or other public papers, is not a legal notice to persons in general not to trust her; though a personal notice, given by the husband to particular persons, is said to be good.

An action lies, and large damages may be recovered, against a person for carrying away and detaining another man's wife.

ELOQUENCE, the art of speaking well, so as to affect and persuade.

Cicero defines it the art of speaking with copiousness and embellishment.

Eloquence and rhetoric differ from each other, as the theory from the practice; rhetoric being the art which describes the rules of eloquence, and eloquence that art which uses them to advantage. For the most part, however, they are used indiscriminately for each other.

ELUL, one of the Hebrew months, answering pretty nearly to our August. There are but twenty-nine days in it. It is the twelfth month of the civil year, and the sixth of the ecclesiastical. Upon the seventh or ninth day of this month the Jews fast, in memory of what happened after the return of those who went to view the promised land.

ELUTRIATION, in metallurgy, the separating the lighter matters from the mixed ores of metals, by means of great quantities of fair water.

ELYSIUM, or **ELYSIAN FIELDS**, in heathen mythology, certain plains, abounding with woods, fountains, verdure, and every delightful object; supposed to be the habitation of heroes and good men, after death.

ELYTROIDES, or **VAGINALIS**, in anatomy, the

the second proper membrane that involves the testes. See **TESTICLE**.

EMANCIPATION, in the Roman law, the setting free a son from the subjection of his father; so that whatever moveables he acquires, belong in propriety to him, and not to his father, as before emancipation.

EMARGINATED, among botanists, an appellation given to such leaves as have a little indenting on their summits: when this indenting is terminated on each side by obtuse points, they are said to be obtusely emarginated; whereas, when these points are acute, they are called acutely emarginated.

EMAUX DE L'Escu, in heraldry, the metal and colour of the shield or escutcheon. See the article **SHIELD**.

EMBALMING is the opening a dead body, taking out the intestines, and filling the place with odoriferous and desiccative drugs and spices, to prevent its putrifying.

EMBARGO, in commerce, an arrest on ships, or merchandize, by public authority; or a prohibition of state, commonly on foreign ships, in time of war, to prevent their going out of port; sometimes to prevent their coming in; and sometimes both, for a limited time.

EMBASSADOR, or **AMBASSADOR**. See **AMBASSADOR**.

EMBASSY, the office or function of an ambassador.

EMBATTLED, in heraldry, the same with crenelle. See **CRENELLE**.

EMBER-WEEKS, or **DAYS**, in the Christian church, are certain seasons of the year set apart for the imploring God's blessing, by prayer and fasting, upon the ordinations performed in the church at such times.

These ordination-fasts are observed four times in the year, viz. the Wednesday, Friday, and Saturday after the first Sunday in Lent, after Whit-Sunday, after the fourteenth of September, and the thirteenth of December; it being enjoined, by a canon of the church, that deacons and ministers be ordained, or made, only upon the Sundays immediately following these ember-fasts.

EMBLEM is a kind of painted ænigma, or certain figures delineated or cut metaphorically, expressing some action, with reflections underneath, which in some measure explain the sense of the device, and at the same time, instruct us in some moral truth, or other matter of knowledge.

EMBLEMENTS, among lawyers, denote the profits of fown lands; but are sometimes used, more largely, for any products that naturally arise from the ground.

EMBOLISMIC, intercalary, or belonging to the embolismus.

The word is derived from the Greek *εμβολισμ*, to insert, or put in.

EMBOLISMUS, the excess of the solar year above the lunar, whereby the lunations happen every subsequent year eleven days sooner than in the foregoing, which, when they amount to thirty-days, make a new month, called the embolismical lunation, or embolismical month; which must be added to make the common lunar year equal to the solar.

EMBOLUS, the moveable part of a pump, or syringe, called also the piston or sucker. See the articles **PISTON**, **PUMP**, **SYRINGE**, &c.

EMBOSSING, or **IMBOSSING**, in architecture and sculpture, the forming or fashioning works in relieve, whether cut with a chissel, or otherwise.

EMBRACE the Volt, in the manege. A horse is said to embrace a volt when, working upon volts, he makes a good way every time with his fore-legs.

EMBRASURE, in architecture, the enlargement made of the aperture of a door or window on the inside of a wall; its use being to give the greater play for the opening of the door, or casement, or to admit the more light. When the wall is very thick, they sometimes make embrasures on the outside.

EMBRASURE, in fortification, a hole or aperture in a parapet, through which the cannon are pointed to fire into the moat or field.

Embrasures are generally twelve feet distant from one another, every one of them being from six to seven feet wide without, and about three within: their height above the platform is three feet on that side towards the town, and a foot and a half on the other side towards the field; so that the muzzle may be sunk on occasion, and the piece brought to shoot low.

EMBROCATION, in surgery and pharmacy, an external kind of remedy, which consists in an irrigation of the part affected, with some proper liquor, as oils, spirits, &c. by means of a woollen or linen cloth, or a sponge, dipped in the same.

EMBROIDERY, a work in gold, or silver, or silk thread, wrought by the needle upon cloth, stuffs, or muslin, into various figures. In embroidering stuffs, the work is performed in a kind of loom, because the more the piece is stretched, the easier it is worked.

EMBRYO, in physiology, the first rudiments of an animal in the womb, before the several members are distinctly formed; after which period it is denominated a fœtus. See the articles **CONCEPTION**, **GENERATION**, and **FOETUS**.

EMBRYO PLANT, the same with plantula seminalis. See the article **PLANTULA**.

EMBRYOTHLASTES, in midwifery, an instrument contrived for breaking the bones, for the more easy extraction of the fœtus, in difficult labours.

EMBRYOTOMY, the cutting a foetus to pieces whilst in the womb, practised in cases of necessity, when there is no other way of saving the mother.

EMBRYULCUS, a hook for extracting the child in difficult labours.

EMERALD, *Smaragdus*, in natural history, the most beautiful of all the class of coloured gems, when perfect. It is found sometimes in the roundish or pebble form, sometimes in the columnar or crystalline one; the pebble emeralds, however, are the most valued; there are multitudes found of the size of a large pin's head, for one of any tolerable bigness; though now and then there occur stones of the size of a horse-bean, and even up to that of a walnut, tho' this last very rare. The pebble emeralds are found loose in the earth of mountains, and in the beds of rivers; the crystalline ones are usually met with adhering to a white, opaque, crystalline matter, though sometimes to pieces of jasper or of the prasiolite, a coarser and softer gem of the same colour, only with some tinge of a yellowish cast, and called the root of the emerald. The pebble emeralds are, in their natural state, bright and transparent, though less glossy than the columnar ones; both are always of a perfect and pure green. It has this green in all the different shades, from very dark to extremely pale, and is probably sometimes colourless, though the English jewellers call it white sapphire.

The *smaragdus* of the ancients, properly so called, was evidently the same with our emerald; though they comprehended also under this name every gem, or even stone of any considerable beauty, and of a green colour.

To counterfeit EMERALDS. Take of natural crystal, four ounces; of red lead, four ounces; verdigrise, forty-eight grains; crocus martis, prepared with vinegar, eight grains; let the whole be finely pulverised and sifted; put this into a crucible, leaving one inch empty; lute it well, and put it into a potter's furnace, and let it stand there as long as they do their pots. When cold, break the crucible, and you will find a matter of a fine emerald-colour, which, after it is cut and set in gold, will surpass in beauty an Oriental emerald.

EMERGENT YEAR, in chronology, the same with epocha, whence any era, or method of reckoning time commences: such is that of the creation of the world, of the birth of our Saviour. See the article **EPOCHA**.

EMERSION, in philosophy, is the rising of any solid above the surface of a fluid, especially lighter than itself, into which it had been violently immersed or thrust.

EMERSION, in astronomy, is the time when any planet that is eclipsed, begins to emerge or get out of the shadow of the eclipsing body.

EMERY, *Smiris*, a compact stone, so hard as

to cut glass like the diamond; impregnated with iron, and a very small portion of copper. It is met with in Norway, Sweden, England, Saxony, and other countries. Bruckman relates, that the emery found at St. Georgenstadt, in Misnia, is superior to the Spanish. It is used for cutting and polishing precious stones, for polishing agate, porphyry, marble, glass, metalline specula, iron and steel, and the various utensils and ornaments made of these kinds of substances: for these purposes the emery is ground in mills, the powder passed through sieves of different degrees of fineness, and thus divided into different sorts, the finest of which, for the nicer uses, are further divided by washing them over several times with water.

Patty of EMERY, a kind of dirty matter found on the lapidaries wheels, containing part of the powder of emery.

EMETICS, *Emetica*, are medicines which induce vomiting.

EMETOLOGY, that part of medicine which treats of emetics.

The word is formed from the Greek, *εμετος*, a vomit, and *λογος*, a discourse.

EMINENCE, a title of honour peculiar to cardinals. See the article **CARDINAL**.

EMINENCE, in the military art, a high or rising ground, which overlooks and commands the low places about it: such places within cannon-shot of a fort, are a great disadvantage; for if the besiegers become masters of them, they can, from thence, fire into the fort.

EMINENTIAL EQUATION, an artificial equation, containing another equation eminently: it is sometimes used in the investigation of the areas of curved-lined figures. See **EQUATION**.

EMISSARY, in a political sense, a person employed by another to sound the opinions of people, spread certain reports, or act as a spy over other people's actions. See the article **SPY**.

EMMENAGOGUES, *EMMENAGOGA*, in physics, are medicines which promote the menses or monthly courses.

EMOLLIENTS are such medicines as sheathe and soften the astringents of the humours, and relax and supple the solids at the same time.

EMPALEMENT of flowers, among the botanists, the same with calyx. See the article **CALYX**.

EMPASTING, or **IMPASTING**, in painting, is the laying on of colours thick and bold, or the applying several lays of colours, so as they may appear thick.

The term is also used when the colours are laid distinct and asunder, and not softened or lost in each other. See the article **COLOURING**.

EMPATTEMENT, in fortification, the same with talus. See the article **TALUS**.

EMPRESS,

EMPERESS, or **EMPRESS**, denotes either the wife of an emperor, or a woman who governs singly an empire, in her own right.

EMPEROR, *Imperator*, a title of honour among the ancient Romans, conferred on a general who had been victorious, and now made to signify a sovereign prince, or supreme ruler of an empire.

EMPETRUM, berry-bearing-beath, in botany, a genus of the diccica class of plants in the Linnaean system, the flower of which consists of three oval oblong petals: in the male are inserted three long, propendent, hairy stamens: and the fruit of the female flower is an orbiculated, depressed, unilocular berry, larger than the cup, containing nine seeds placed circularly.

EMPHASIS, in rhetoric, a particular stress of the voice and action, laid on such parts or words of the oration, as the orator wants to enforce upon his audience. See **ACCENT**.

EMPHYSEMA, in physic, is any flatulent tumour, generally taken for a soft one, arising from air that is contained in the cells of the membrana cellulosa.

The word is Greek, from *εμ* and *φυσω*, to inflate.

EMPIRE, *Imperium*, in political geography, a large extent of land, under the jurisdiction or government of an emperor. See the article **EMPEROR**.

EMPIRIC, an appellation given to those physicians who conduct themselves wholly by their experience, without studying physic in a regular way. Some even use the term, in a still worse sense, for a quack who prescribes at random, without being at all acquainted with the principles of the art.

EMPLASTER, *Emplastrum*, in pharmacy, the same with plaster. See **PLASTER**.

EMPYEMA, in physic, is, strictly speaking, a collection of purulent matter, in any part whatsoever; but it generally signifies that in the cavity of the breast only; and which sometimes happens upon the opening of abscesses, or ulcerations of the lungs, or membranes inclosing the thorax.

The word is derived from the Greek, *εμ*, and *πυον*, purulent matter.

EMPYREUM, a term used by divines for the highest heaven, where the blessed enjoy the beatific vision.

EMPYREUMA, among chemists and physicians, the fiery taste or offensive smell which brandies, with.

and other bodies prepared by fire, are impregnated

EMRODS, or **HÆMORRHOIDS**. See the article **HÆMORRHOIDS**.

EMULGENT, or **RENAL ARTERIES**, those which supply the kidneys with blood; being some-

times single, sometimes double on each side. See **ARTERY**.

EMULSION, in pharmacy, properly signifies medicines which resemble milk. Thus solutions of gums, resins, or spermaceti, made by means of the yolk of an egg, in a proper vehicle, are called emulsions.

EMUNCTORY, in anatomy, a general term for all those parts which serve to carry off the excrementitious parts of the blood and other humours of the body. Such more especially are the kidneys, bladder, and most of the glands.

EMUSCATION, in gardening and husbandry, implies the clearing trees from moss, &c.

ENÆMON, *enæmon*, in medicine, an epithet often applied by Hippocrates and Galen; to such topical medicines as are appropriated to a wound newly inflicted, before the blood be stopped.

ENÆOREMA, in medicine, that pendulous substance which floats in the urine. It is also called *sublimamentum*, and *nubeculae*, from its resemblance to little clouds.

ENALLAGE, in grammar, is when a possessive pronoun is put for a relative, or one mood or tense of a verb is put for another, &c.

ENALLAGE, in rhetoric, is a figure whereby the discourse is changed and reversed, contrary to all the rules of the language; but this is not done altogether at the pleasure, or without reason.

ENALURON, according to Guillim, is a border charged all round with birds; though others will have it to signify, in ornaments, or form of a border.

ENAMEL, vulgarly called **AMEL**, is a kind of coloured glass, used in painting in enamel.

ENAMEL Painting, a species of painting differing from other kinds of painting, in employing, as a vehicle for the colours to hold the parts together, and bind them to the ground they are laid upon, glass or some vitreous body; which being mixed with the colours, and fused or melted by means of heat, becomes fluid; and having incorporated with the colours in that state, forms together with them a hard mass when grown cold; and answers, therefore, the same end in this, as oil, gum-water, size, or varnish, in the other kinds of painting.

ENARTHROSIS, in anatomy, a species of diarthrosis. See the article **DIARTHROSIS**.

ENCÆNIA, the name of three several feasts celebrated by the Jews in memory of the dedication, or rather purification, of the temple, by Judas Maccabeus, Solomon, and Zorobabel.

This term is likewise used in church history for the dedication of Christian churches.

ENCAMPMENT, the pitching of a camp. See the article **CAMP**.

ENCANTHIS, in surgery, a tubercle arising either from the caruncula lachrymalis, or from the adjacent

adjacent red skin; sometimes so large, as to obstruct not only the puncta lachrymalia, but also part of the sight, or pupil itself.

It is of two kinds, viz. mild, without hardness or pain; or malignant, which is livid and very painful. The mild kind is to be treated first by scarifying, and afterwards applying escharotic or caustic medicines; and if this proves insufficient, the tumour may be touched, but with great caution, with lapis infernalis; and to divert the humours from the eye, issues and setons, with phlebotomy and cooling purges, are proper. If all these fail, the surgeon is to extirpate the tumour; in which case it is better to leave part of the morbid tubercle, than cut off any part of the lachrymal caruncle, as the remains of it may be afterwards cleared away by escharotics. After the operation, it is proper to apply deterring and healing medicines, or a collyrium of lapis tutiæ, myrrh, &c. till the wound is healed.

As to the malignant encanthis, inclining to be cancerous, it is generally better to let it alone, and to mitigate its uneasiness with cooling and lenient collyria, rather than exasperate it by the operation, or by escharotic medicines.

ENCAUSTICE and **ENCAUSTUM**, the same with enamelling and enamel.

ENCEINTE, in fortification, is the wall or rampart which surrounds a place, sometimes composed of bastions or curtains, either faced or lined with brick or stone, or only made of earth. The enceinte is sometimes only flanked by round or square towers, which is called a Roman wall.

ENCEPHALI, in medicine, worms generated in the head, where they cause so great a pain, as sometimes to occasion distraction.

ENCEPPE, in heraldry, denotes fettered, chained, or girt about the middle, as is usual with monkeys.

ENCHANTER, a person supposed to practise enchantment, or fascination.

ENCHASING, **INCHASING**, or **CHASING**, the art of enriching and beautifying gold, silver, and other metal-work, by some design, or figures represented thereon, in low relief.

ENCHYSMA, in medicine, the same with clyster. See the article **CLYSTER**.

ENCLITICA, in grammar, particles which are so closely united with other words, as to seem part of them, as in *virumque*, &c.

There are three enclitic particles in Latin, viz. *que, ne, ve*; but there are a great many in the Greek, as *τε, τοι, μοι, σι, σοι*, &c.

ENCRATITES, *Encratites*, in church history, heretics who appeared towards the end of the second century: they were called Encratites, or Continentes, because they gloried in abstaining from marriage, and the use of wine and animal food. Their chastity, however, was a little suspected, on account of their using all sorts of means to draw

women into their sect, and always keeping company with them.

ENCROACHMENT, or **INCROACHMENT**, in law. See **INCROACHMENT**.

ENCYCLOPÆDIA, the circle of arts and sciences.

The word is formed from the Greek *εν*, in, *κυκλος*, a circle, and *παιδεια*, art, science; or learning.

ENDECAGON, in geometry, the same with hendecagon. See **HENDECAGON**.

ENDEMIC, or **ENDEMICAL DISEASES**, those to which the inhabitants of particular countries are subject more than others, on account of the air, water, situation, and manner of living.

The word is derived from the Greek *εν*, in, and *δημος*, people.

ENDIVE, in botany, a plant much used as a salad in winter with us, of which there are different varieties; but the sort which is most cultivated here is the curled leaved endive. The seasons for sowing the seeds is at different periods, to continue the plants in perfection, as in May, June, July and August: they are afterwards planted out in rows at about a foot asunder; and when grown to their full size of foliage, should be blanched in order to make them more tender, and to take off the bitterness which they have when green. Those of the early sowing may be only tied up to whiten them: but those for winter use should be taken up when dry, and laid in on the side of a trench of earth to their tops, which will prevent the frost or wet from damaging them, observing to close their leaves so as no earth may get in their hearts.

Another sort, called by some Batavian endive, hath broad leaves; and in taste and appearance approaches nearer to lettuce than the other sorts. This of late years have been introduced into the English gardens, and is managed as the former.

For the general characters and medicinal virtues of endive. See the article **CICORIUM**, of which it is a species.

ENDORSE, in heraldry, an ordinary, containing the eighth part of a pale, which Leigh says is only used when a pale is between two of them.

ENDORSED, *Endorsé*, in heraldry, is said of things borne back to back, more usually called *adosse*.

ENDOWMENT, in law, denotes the settling a dower on a woman; though sometimes it is used figuratively, for settling a provision upon a person on the building of a church; or the severing a sufficient portion of tithes for a vicar, when the benefice is appropriated.

ENEMA, in medicine, the same with clyster. See the article **CLYSTER**.

ENEMY, in law, an alien or foreigner, who publicly invades the kingdom.

ENERGUMENS, in church history, persons supposed to be possessed by the devil, concerning whom there

Fig. 2. Engine.

Fig. 1. Engine.

there were many regulations among the primitive Christians.

They were denied baptism, and the eucharist; at least this was the practice of some churches: and though they were under the care of exorcists, yet it was thought a becoming act of charity to let them have the public prayers of the church, at which they were permitted to be present. See the article EXORCISM.

ENERGY, *ενεργεια*, a term of Greek origin, signifying the power, virtue, or efficacy of a thing. It is also used, figuratively, to denote emphasis of speech. See EMPHASIS.

ENFILADE, in the art of war, is used in speaking of trenches, or other places, which may be scoured by the enemy's shot, along their whole length. In conducting the approaches at a siege, care must be taken that the trenches be not enfiladed from any work of the place. See the article TRENCHES.

ENFRANCHISEMENT, in law, the incorporating a person into any society or body politic: thus, where any person is enfranchised, or made free, of any city, borough, or company, he is said to have a freehold therein during life; and cannot, for barely endeavouring any thing against the corporation, forfeit the same.

Naturalization is also another kind of enfranchisement. See NATURALIZATION.

ENGASTRIMYTHI, in pagan theology, the pythians or priestesses of Apollo, who delivered oracles from within, without any action of the mouth or lips.

ENGINE, in mechanics, is a compound machine, made of one or more mechanical powers, as levers, pulleys, screws, &c. in order to raise, project, or sustain any weight, or produce any effect which could not be easily effected otherwise.

Engines are extremely numerous; some used in war, as the battering-ram, ballista, waggons, chariots, &c. others in trade and manufactures, as cranes, mills, presses, &c. others to measure time, as clocks, watches, &c. and others for the illustration of some branch of science, as the orrery, cometarium, and the like. See BATTERING-RAM, BALLISTA, &c.

In general we may observe, concerning engines, that they consist of one, two, or more of the simple powers variously combined together; that in most of them the axis in peritrochio, the lever, and the screw, are the constituent parts; that in all a certain power is applied to produce an effect of much greater moment; and that the greatest effect, or perfection, is when it is set to work with four-ninths of that charge which is equivalent to the power, or will but just keep the machine in equilibrio. See the articles MAXIMUM and MECHANICS.

In all machines, the power will just sustain the

weight, when they are in the inverse ratio of their distances from the center of motion. See the article POWER and EQUILIBRIUM.

It being of the utmost importance to diminish the friction of engines, several contrivances have been invented for that purpose. See the article FRICTION.

ENGINE for extinguishing fires, a machine for raising a considerable quantity of water, in one continued stream, for the extinguishing accidental fires. See a perspective view of the whole engine, ready for working, in plate XLVIII. fig. 3.

The nature and effect of this engine will be easily understood from a perpendicular section of it, represented, fig. 4. The water is raised by the pressure of the atmosphere, by the force of pistons, and by the spring of condensed air, in the following manner: thus, when the piston R is raised, a vacuum would be made in the barrel T V, did not the water follow it from the inferior canal E M, through the valve H, which rises through the tube E F, immersed in the water of a vessel, by the pressure of the atmosphere on the surface thereof. By the depression of the piston R, the water in the barrel T V is forced through the superior canal O N, to enter by the valve I, into the air-vessel *a b c d*; and the like being done alternately by the other barrel W X, and its piston S, the air-vessel is by this means continually filling with water, which greatly compresses the air above the surface of the water in the vessel, and thereby proportionably augments its spring, which is at length so far increased, as to react with great force on the surface Y Z of the subjacent water; which ascending through the small tube *e f*, to the stop-cock *p*, is there, upon turning the cock, suffered to pass through a pipe *b*, fixed to a ball and socket, from the orifice of which it issues with a great velocity, to a very great height or distance, in a continued stream, directed every way, or to any particular place, by means of the ball and socket.

The greatest artifice of this engine is its contrivance to produce a continual stream, which is done by compression, and the consequent increased elasticity of the air in the barrel *a b c d*, called the air-vessel: for the air, being an elastic fluid, will be capable of compression in any degree by the water forced in through the valves at I K; and, since the force of the air's spring will always be inversely as the space which it possesses, it follows, that when the air-vessel is half full of water, the air will be compressed into half the space it possessed at first, and therefore its spring will be twice as great as at first.

But this spring at first was equal to the pressure of the atmosphere; for if it was not, it could not have sustained or resisted the pressure of the atmosphere which stood over it, and consequently could not have filled the vessel before the water was driven

in; which yet we find it did, and maintained an equilibrium with the common air.

The vessel then being half filled with water, or the air compressed into half its first space, its spring will be in this case equal to twice the pressure of the atmosphere; and therefore, when the stop-cock at *p* is turned, the air within the subjacent water, with twice the force it meets with from the external air in the pipe *ef*, will cause the water to spout out of the engine to the height of thirty-two or thirty-three feet, if the friction be not too great.

When the air-vessel is $\frac{2}{3}$ full of water, the space which the air takes up is only $\frac{1}{3}$ of its first space; whence its spring being three times as great as that of the common air, it will project the water with twice the force of the atmosphere, or throw it to the height of 64 or 66 feet. In the same manner, when the air-vessel is $\frac{1}{2}$ full of water, the air will project it to the height of 96 or 99 feet; and when $\frac{1}{3}$ full of water, to the height of 132 feet.

As the air-vessel is the cause of the continual stream, we may naturally infer that, if such an air-vessel were adapted to the common house-pump, it would then become a fire-engine, or very useful for extinguishing fires that may happen in or near the house. Now this may be effected in a manner, either the same with, or analogous to, that which follows: ABCD (*fig. 5.*) is the barrel of the pump, PH the rod and piston; CW the pipe going down to the water of the well at W; towards the lower part of the barrel is a short tube, by which the air-vessel FE is fixed to, and communicated with, the barrel of the pump. AMNL is a collar of leather so fixed on the top of the barrel, and adapted to the rod, that it may move freely in the leather, without permitting the air to pass in or out between. The nozzle or spout D has a stop-cock S to shut off the water, or let it pass out as required. Q is a piece screwed on to direct the stream by a small pliant leathern pipe at the end.

Now it is plain, when the piston is raised from the bottom of the pump-barrel, the water above it will be forced into the air-vessel, and there compresses the air, the stop cock being shut; it will also compress the air on the top of the barrel, for the water will not be higher than the spout D at first, when the stop-cock is shut: but afterwards, as the air is confined, it will be compressed at top, and the water will rise to L.

This compressed air, in each place, will act upon the water by its spring, and upon turning the stop-cock, will force it out in a continual stream, through a pipe at Q; and with a greater or lesser degree of force, as occasion requires, that being absolutely in the power of the person working the pump. This invention we owe to the learned Sir James Creed.

FIRE ENGINE, or Steam ENGINE, a machine for raising water by the help of fire. The fire-engine is the most admirable, curious, and com-

pounded machine that we find among all those whose inventions have been owing to the discoveries of modern philosophy, and which affords the greatest advantages to mankind. The fire-engine is of two sorts, of which we shall here give the theory and figures of each, according to the latest perfection in which they are made.

The marquis of Worcester, in his century of inventions, published in the year 1663, is probably the first who proposed raising great quantities of water by the force of fire turning water into a steam; and he mentions some engine of this kind, which he says played a continual stream, in the manner of a fountain, forty feet high. He also says, that a person attending it turned two cocks; that one vessel of water being consumed, another begins to force and re-fill with cold water; and this alternately and successively, the fire being attended and kept constantly burning by the same person, in the interim between the turning the cocks.

Captain Savery, having read this account, immediately attempted to raise water by fire, and was the first who erected an engine for this purpose, in the form we have since had them. To secure the invention to himself, he purchased all the books that were to be found, printed by the marquis upon that occasion, and burnt them; and at the same declared that he found out the method by accident. He made many experiments to bring the machine to perfection, and erected several for gentlemen's seats.

But the progress of the engine was stopped, till long time afterwards, when Mr. Newcomen and Mr. J. Cawley contrived another way to raise water by fire, where the steam to raise the water from the greatest depths of mines is not required greater than the pressure of the atmosphere; and this is the present structure of the engine, which is now of about fifty-five years standing.

We shall shew, under the article PUMP, that water may be drawn from any depth by a compound pump. Suppose the depth = 150 feet, and the diameter of the pump at plate XLIX. *fig. 1.* be $7\frac{3}{4}$ inches, then the weight of a cylindric column of water 150 feet high, and $7\frac{1}{4}$ inches diameter, will be about 3000 lb weight. If now the rod of this pump were hung by a chain to the end of the lever *bb*, as at H, and at the other end another power was applied, as at L, with a superior force, the pump might be worked, and the water raised by that power.

Now this power cannot be human, or the strength of man; for it will require a hundred men to pull down the beam, each pulling with the force of thirtypounds; and an hundred men to relieve them, when weary; for the pump in a mine must not stand still: but two hundred men would be too expensive. If we allow horses, and one horse equal to five men, there must be twenty horses working at a time, and twenty

more.

more to relieve these; which great number of horses, though less expensive than the men, will be found too great for most mines: and neither men nor horses were able to give more than fifteen or sixteen strokes in a minute.

Some other power therefore must be applied, and this may be effected as follows: B is a large boiler, whose water, by the fire under it, is converted into an elastic steam. The great cylinder C C is fixed upon it, and communicates with it by the pipe D d; on the lower orifice of which, within the boiler, moves a broad plate, by means of the steam-cock, or regulator E 10, stopping or opening the passage to prevent or permit the steam to pass into the cylinder, as occasion requires. The diameter of the pipe D is about four inches.

The steam in the boiler ought always to be a little stronger than the air, that when let into the barrel, it may be a little more than a balance to the external air, which keeps down the piston at the bottom d n. The piston being by this means at liberty, the pump-rod will, by its great weight, descend at the opposite end to fetch a stroke; for the weight of seventy or eighty yards of iron rod amounts to nine or ten hundred weight; whereas the piston, and other weights at the other end, is not above four or four and a half hundred weight. The end of the lever at the pump, therefore, will always preponderate the other, and descend when the piston is at liberty.

The handle of the steam cock E 10, being turned towards n, opens a pipe D to let in the steam; and being turned towards O, it shuts it off, that no more can enter. The piston is now raised towards the top of the barrel at C, and the barrel is full of steam. The lever O 1 must then be lifted up, to turn, by its teeth, the injecting cock at N, which permits the water brought from the cistern g, by the pipe g M N, to enter the bottom of the barrel at n, where it flies up in the form of a fountain, and striking against the bottom of a piston, the drops, being driven all over the cylinder, will, by their coldness, condense the steam into water again, and precipitate it to the bottom of the barrel.

Mr. Henry Beighton made an experiment to determine the rarity of the steam, and found the content of the barrel of steam was 113 gallons; and since there were sixteen strokes in a minute, therefore $113 \times 16 = 1808$ gallons of steam per minute. He also observed, that the boiler required to be supplied with water at the rate of five pints per minute: and since 282 cubic inches make a gallon, $35 \frac{1}{4}$ make a pint, and $5 \times 35 \frac{1}{4} = 176 \frac{1}{4}$ in five pints; also the cubic inches of steam are $1808 \times 282 = 509856$; if then we say, as $176 \frac{1}{4} : 509856 :: 1 : 2893$; or one cubic inch of water is expanded into 2893 inches of steam; consequently the steam in the barrel is reduced to $\frac{1}{2893}$ part, when turned to water by the jet of cold water; and therefore a suf-

ficient vacuum is made in the barrel, for the piston to descend unbalanced, by the pressure of the air.

The piston being forced down, raises the other end of the lever, and consequently the piston of the pump which brings up and discharges the water at p. Now this whole operation of opening and shutting the steam regulator and injection-cock, will take up but little more than three seconds; and will therefore produce very well sixteen strokes in a minute.

That the cistern g may always be supplied with water, there is an arch x fixed near the arch H at the pump-end, from whence another pump rod k, with its piston, draws water from a small cistern near the mouth of a pit, supplied from the water raised at p, and forces it up the pipe m m m into the cistern g, which, therefore, can never want water.

That the leathers of the piston C may be always supple and swelled out so as to be always air-tight, a small stream of water is supplied from the injecting pipe M by the arm z. On the top of the cylinder is a larger part or cup L, to hold the water that lies on the piston, lest it should overflow when the piston is got to its greatest height, as at W; at which time, if the cup be too full, the water will run down the pipe V to the waste-well at Y.

The water in the boiler which wastes in generating steam, is supplied by a pipe I i about three feet long, going into the boiler a foot below the surface of the water. On the top of this pipe is a cup or funnel I, supplied by the pipe W with water from the top of the cistern, which has the advantage of being always warm, and not so apt to check the boiling of the water in the copper.

That the boiler may not have the surface of the water too low, which would endanger bursting, or too high, which would not have room enough for steam, there are two gage-pipes at G; one going a little below the surface of the water when at a proper height, and the other standing a little above it. When every thing is right, the stop-cock of the shorter pipe, being open, gives only a steam, and that of the long one water; but, if otherwise, both cocks will give steam when the surface is too low, and both give water when it is too high; and hence the cock which feeds the boiler at I may be opened to such a degree, as always to keep the surface of water to its due height.

The cold water, constantly injected into the cylinder to condense the steam, is carried off by the eduction-pipe d T Y, going from the bottom of the cylinder to the waste-well Y, where going a little under water, it has its end turned up, with a valve Y, to keep the air from pressing out into the pipe, but permitting the injected water coming the other way to be discharged, whereby the cylinder is kept empty.

Lest the steam should grow too strong for the boiler, and burst it, there is a valve fixed at b, with a perpendicular wire standing up from the middle of

it, to put weights of lead upon, by which to examine the strength of the steam pushing against it from within. Thus the steam is known to be as strong as the air, if it will raise up so much weight on the valve, as is at the rate of fifteen pounds to an inch square; because that is the weight of air, nearly, on every square inch. When the steam becomes stronger than is required, it will lift up the valve, and go out. This valve is called the puppet-clack.

The steam has always a variable strength, yet never $\frac{1}{10}$ stronger or weaker than common air: for it has been found that the engine will work well when there is the weight of one pound on each square inch of the valve *b*. This shews that the steam is then $\frac{1}{10}$ part stronger than the common air. Now as the height of the feeding-pipe from the funnel *F* to the surface of the water *S*, is not above three feet, and three feet and a half of water is $\frac{1}{10}$ of the pressure of the air; if the steam were $\frac{1}{10}$ part stronger than air, it would push the water out at *E*; which, since it does not, it cannot be stronger than air, even in this case, where, the regulator being shut, it is most of all confined.

When the regulator is opened, the steam gives the piston a push, which rises it up a little way; then filling a greater space, it comes to be of the same strength, and so a balance to the atmosphere; thus the piston, being at liberty, rises to the top *W*. The steam, now expanded into the whole capacity of the cylinder, is weaker than the air, and would not support the piston, were it not for the greater weight at the other end of the lever, which keeps it up. The steam each stroke drives the injected water of the preceding stroke out of the eduction pipe *d T Y*, and would itself follow, and blow out at the valve *Y*, which is not loaded, if it were stronger than the air, which it never does. If it were exactly equal to the strength of the air, it would just drive all the water out at *Y*, but could not follow itself, the pressure being on each side the valve equal by supposition. If it be weaker than the air, it will not force all the water out of the pipe *d T Y*, but the surface will stand, suppose, at *T*, where the column of water *T Y*, added to the strength of the steam, is equal to the pressure of the air. When the steam is $\frac{1}{10}$ weaker than the air, the height *T Y* = three feet and a half. Now, since the whole perpendicular distance from *d* to *Y* is but four feet, and the steam always sufficient to expel the water; it is plain it can never be more than $\frac{1}{10}$ part weaker than the air, when weakest.

There is air in all the water injected; and though that air cannot be taken out or condensed with the steam, yet will it precipitate and fall through the steam to the bottom of the cylinder, as being much heavier. For steam is to water, as 1 to 2893, in its density; but the density of air is to that of water, as 1 to 864, nearly; therefore, the rarity of

steam is to that of air, as 2893 to 864; the air will, therefore, fall through the steam to the bottom, and from thence be driven out through a small pipe opening into the cup at 4, on which is a valve. Now, when the steam first rushes into the cylinder, and is a little stronger than the outward air, it will force the precipitated air to open the valve at 4, and make its escape; but the steam cannot follow, because it is weaker than the outward air, as the piston gives it room by ascending to expand. This valve, from the noise it makes, is called the snifting-clack.

Among the greatest improvements of this engine, we may reckon that contrivance by which the engine itself is made to open and shut the regulator and injunction-cock, and that more nicely than any person attending could possibly do it. For this purpose, there is fixed to an arch 12, at a proper distance from the arch *P*, a chain, from which hangs a perpendicular piece or working beam *QQ*, which comes down quite to the floor, and goes through it in a hole, which it very exactly fits. This piece has a long slit in it, and several pin-holes and pins, for the movement of small levers destined to the same office of opening and shutting the cocks, after the following manner:

Between two perpendicular pieces of wood on each side, there is a square iron axis *AB* (*fig. 2*) which has upon it several iron pieces of the lever kind. The first is the piece *CED*, called the *Y*, from its representing that letter inverted by its two shanks *E* and *D*; on the upper part is a weight *F* to be raised higher or lower, and fixed, as occasion requires. This *Y* is fixed very fast upon the said iron axle *AB*.

From the axle hangs a sort of an iron stirrup *IK LG*, by its two hooks *IG*, and having on the lower part two holes *K, L*, through which passes a long iron pin *LK*, and keyed in the same. When this pin is put in, it is also passed through the two holes in the ends *E, N*, of the horizontal fork or spanner *EQN*, joined at its end *Q*, to the handle of the regulator *V 10*. From *Q* to *O* are several holes, by which the said handle may be fixed to that part of the end which is most convenient.

Upon this axis *AB* is fixed at right angles to the *Y*, an handle or lever *G₄* which goes on the outside of the piece *Q₂*, *Q₂*, and lies between the pins. Another handle is also fastened upon the same axle, viz. *H₅*, and placed at half a right angle to the former *G₄*; this passes through the slit of the piece *Q₂*, *Q₂*, lying on one of the pins. Hence we see, that when the working beam goes up its pin in the slit, it lifts up the spanner *H₅*, which turns about the axle so fast, as to throw the *Y*, with its weight *F*, from *C* to *6*, in which direction it would continue to move, after it had passed the perpendicular, were it not prevented by a strap of leather fixed to it at *6*, and made fast at the ends.

m and *n*, in such a manner as to allow the *Y* to vibrate backwards and forwards about a quarter of a circle; at equal distances on this side, and that of the perpendicular.

As things are represented in the figure, the regulator is open, its plate *TY* being shewn on one side the pipe *S*, which joins the cylinder and boiler. The piston is now up, and also the working beam near its greatest height; the pin in the slit has so far raised the spanner *H* 5, that the weight *F*, on the head of the *Y*, is brought so far from *u*, as to be past the perpendicular, and ready to fall over towards *m*, which, when it does, it will by its shank *E*, with a smart blow, strike the iron pin *KL*, and drawing the fork horizontally towards the beam *Q*, will draw the end *ro* of the regulator towards *6*, and thereby shut it; by slipping the plate *Y* under the holes of the throat-pipe *S*.

Immediately after the regulator is shut, the beam rising a little higher, with its pin *S* on the outside upon the lower part, lifts up the end *k* 1. of the handle of the injection-cock, and opens it by the turning of the two parts with teeth. The jet immediately making a vacuum, the beam again descends, and the pin *r*, depressing the handle *k* 1, shuts the injection-cock; and the beam continuing to descend, the pin *p* bears down the handle *G* 4, and throwing back the *Y*, its shank *D* throws forward the fork *NQ*; and again opens the regulator to admit fresh steam. After this, every thing returns as before; and thus is the engine most wonderfully contrived to work itself. After the engine had been made, as above described, for many years, it received another improvement of very great advantage; and that was, instead of feeding the boiler with warm water from the top of the cylinder, by the pipe *W* (fig. 1.) above, and *F* below, they contrived to supply it with the scalding hot water which comes out of the eduction-pipe *d* *TY*, which now, instead of going to the waste-well at *Y*, was turned into the boiler on the top part; and as the eduction-pipe before went out at the side of the cylinder, it was now inserted in the bottom of the same; and though the pressure of steam in the boiler be somewhat stronger in the cylinder, yet the weight of water in the eduction-pipe, being added to the force of steam in the cylinder, will carry the water down continually, by overcoming the resistance in the boiler.

This is the lever-engine with the improvements of Mr. Newcomen and others; but as captain Savery's, or rather the marquis of Worcester's, is very cheap in respect of this machine, and as it is, also applicable with great advantage when the height to which the water is to be raised does not exceed 100 or 150 feet, we shall here subjoin a view of that engine, with the improvements of Dr. Defaguliers.

The boiler *BB* (plate *L*, fig. 2.) is a large copper body of a globular form, which will best of all with-

stand the very great force of steam, that is in this case necessary. Round the body of this boiler the fire and flame are conducted, as shewn at *TTT*. It has a copper cover screwed on, which contains the steam-pipe *CD*, and two gage-pipes *N*, *O*, which, by turning their cocks, shew the height of the surface of the water within, as in the other engine.

On the same cover at *P* is a valve, over which lies a steelyard, with its weight *Q* to keep it down, the strength of the vapour being this way most exactly estimated: for being in the nature of a lever of the third sort, it is plain, if the beam of the lever be divided into ten equal parts, and the first of them be upon the middle of the valve, and the weight *Q* hangs at the second, third, fourth, &c. division, that then the force of the steam which can raise up the valve will be two, three, four, &c. times as great as the weight. If the area of the valve be a square inch, and *Q* = 15 pounds, hanging at the second division, is raised by a steam pushing up the valve, it will shew the steam will then press with the force of two atmospheres; but great care must then be taken about it, lest the steam, so very strong, burst the boiler to pieces.

The steam is carried from the boiler to the copper-vessel *A*, by means of the pipe *CD*; and is let into the same by turning the handle *K* of the steam-cock *DL*. The key of this cock is kept down by the screw *L*, and held up by the gibbet *DL*. The handle turned from *K* to *k*, admits a passage to the steam into the copper receiver *A*.

This receiver *A* communicates at bottom with the suction-pipe *ZH* going down to the water *H* in the well *X*; and above, with the forcing pipe *EE*, which goes up a little above the water of the reservoir *R*; between these two pipes are two valves *F* and *G*, both opening upwards. The steam being let in upon the water of the receiver *A*, forces it up the valve *F*, and the pipe *EE*, to the reservoir, and then the said receiver is full of hot steam.

This steam, in the receiver, is condensed by a jet of cold water coming from the forcing-pipe, by the small pipe *MI*, being let in and shut off by the cock at *M*. The steam being condensed by this jet, will be reduced to a very small space, and so make a vacuum: upon which the water in the well will rush up the forcing-pipe to restore the equilibrium, and thus again fill the receiver *A*; the little air being compressed within a small compass at the top above *ab*.

That there may be always water in the forcing-pipe for the jet, there is a little pipe which brings the water to it from the reservoir, with the small stop-cock *Y* to shut it off upon occasion. The valves at *F* and *G* are examined at any time, by unscrewing the pin *1* to loosen the strap *2*, and let down the flanch *3*; all which parts are shewn larger in fig. 2.

By the particular contrivance of the cock at *DL*, and

and its key, the water is made to pass from the force-pipe to the boiler, to supply the waste in steam. This is plainly shewn in the section of the cock and key, where *g* is the top of the key; *h* is a hole on one side, which goes down to the bottom to convey the steam or jet of water alternately to the receiver; *i* is a notch on the other side, to take in the water from the force-pipe, and conduct it to the boiler *B*. How this is done is easy to conceive from a view of the two sections of the cock and key in two positions within it.

The boiler may hold five or six hogheads, and the receiver one hoghead per hour. This steam makes a vacuum so effectually, as to raise water from the well to the height of 29 or 30 feet; and suppose the steam able to lift up the steelyard, with its weight hanging at the sixth division, it will then be able to raise a column of water about 50 yards high, as being then six times stronger than the pressure of the air, as is easily understood from what has been said under *ENGINE for extinguishing Fires*, the water being raised in a similar manner in both machines; there by the pressure of condensed elastic air, and here by the pressure of rarefied elastic steam.

The elasticity of the steam increasing with its heat, and the space, into which it endeavours to expand itself, being as its elasticity or strength, and since we know that water expanded into vapour, of the same strength of the air, occupies near 3000 times the space as before, it follows, that, when the steam has twice that strength, it will be expanded into 6000; if it be five times as strong as the air's spring, it will become expanded into 15000 times that space, and so on, beyond the reach of experiments; from all which it appears, how near a perfect vacuum we may approach by this engine, or any other, by means of rarefied vapours.

The following engine, which was invented by Mr. De Moura of Portugal, F. R. S. is an improvement of that above described, as it is rendered capable of working itself.

This engine consists in a receiver, a steam, and an injection-cock; a suction and a forcing-pipe, each furnished with a valve; together with a boiler, which, on account of its bulk and weight, was not sent with the rest; but, as it may be of the common globular shape, and having nothing particular in its construction, a description of it will not be necessary; as also, the rest of these parts already mentioned being essential to every machine of this kind, a farther account of them may be dispensed with. What is peculiar to this engine, is a float within the receiver, composed of a light ball of copper, which is not loose therein, but fastened to the end of an arm, which is made to rise and fall by the float, while the other end of the arm is fastened to an axis; and consequently, as the float moves up and down, the axis is turned round one way or the

other. This axis is made conical, and passes through a conical socket; which last is soldered to the side of the receiver. Upon one of the ends of the axis, which projects beyond the socket, is fitted a second arm, which is also moved backward and forward by the axis, as the float rises and falls. By these means, the rising and falling of the surface of the water within the receiver communicates a correspondent motion to the outside, in order to give proper motions to the rest of the gear, which regulates the opening and shutting of the steam and injection-cocks; and serves the same purpose as the plug-frame, &c. in Newcomen's engine. The particular construction and relation of those pieces will better appear by the figure and references, than can be done by a general description.

A B, (*fig. 1.*) an arm, which is fastened to *ab*, a conical axis, which goes through a conical socket in *C*, a triangular piece soldered to the receiver. This piece has this shape to give liberty to the arm to rise and fall, that carries the float on the inside. *DE* is a small cistern soldered to the receiver, which, being kept full of water, keeps the axis and socket air-tight. This cistern is constantly kept full of water, by means of a small leakage through the wooden peg *c*; which follows the packthread *ed* to the cistern.

e is a small weight to counterpoise the float within.

f, is a slider, which being set nearer to, or farther from, the axis, will rise or fall a greater or lesser space, as may be required; and is fastened by the screw *g*. This slider is furnished with a turn-about, *hi*, which is also fastened by a screw, and not at the end *i*, and serves to adjust the length of *F G G H*, a chain, which gives motion, by means of the shorter chain *kl*, to *I K L*, the balance, which opens and shuts the cocks; and moves upon the small axis *L*.

G, *G*, are two pulleys supported by two arms that are fastened to the side of the receiver, and give the chain a proper direction in order to move the balance.

M N is the steam-cock; the end *N* being supposed to be detached from a pipe that gives it communication with the boiler.

O is the injection-cock, whose key is turned by the arm *Om*.

P Q is the injection-pipe, communicating between the forcing-pipe above the valve, and the top of the receiver.

R S is the arm by which the key of the steam-cock is worked.

I, *K*, two rollers annexed to the balance, which is furnished with two small rollers, *n*, *o*, which open and shut the injection-pipe, by acting upon the arm *Om*, in such a manner, that when the steam-cock is opened, the injection is shut, and vice versa.

T is a bell of advice, which, moving along with the balance, continues to ring as long as the engine is at work.

V is a cock which serves to discharge the air from the receiver, and is opened by hand when necessary.

W is a weight sufficient to raise the balance to a perpendicular posture, when it is inclined to the right, and also to overcome the friction of the float, axis, pulleys, chain, &c.

To put the engine in motion, press down the arm A B, which will bring the balance over to the right side, and in its motion will open the steam-cock, and shut the injection; set open the cock at V, that the air may be discharged by the entrance of the steam into the receiver. This being done, shut that cock, and let go the arm; the weight W will bring over the balance to the left, and in its motion shut the steam-cock, and open the injection; this presently condensing the steam into water, in a great measure, leaves a vacuum in the receiver. Things remain in this situation, till the pressure of the atmosphere has caused the water to mount through the suction-pipe into the receiver, where, as its surface rises, it causes the float to ascend; and, depressing the arm A B, raises the balance till it has passed the perpendicular; and in its descent, which is done by its own gravity, the roller K lays hold of the arm R S, again opens the steam-cock, and shuts the injection. The receiver being now almost filled with water, the balance cannot return till the surface of the water therein subsides, and suffers the float to descend. This is performed by the elasticity of the steam, which, at the same time that it fills the receiver, drives out the water through the forcing-pipe; and when the surface is descended so low as to suffer the weight W to bring the balance beyond the perpendicular towards the left, it then falls of its own accord, and, in falling, the roller I lays hold of the arm R S, shuts the steam-cock, and opens the injection as above.

When the engine is desired to be stopped, observe, when the balance lies to the right, to turn round the arm O m of the injection-cock, so that the tail of the steam-cock may miss it in the next motion; so that at the same time that the receiver is filled with steam, and the steam-cock shut, the injection not being opened, the motion will stop for want thereof.

In the Philosophical Transactions, N^o. 461, there is an account of an improvement made in the steam-engine by Mr. Paine, as follows: He has contrived two iron pots, or vessels, of a conical form, inverted, as represented by A B E F (fig. 4.) on the upper part of which is fixed a round globular copper-head, about five feet and a half in diameter, as L M N. There is then placed on the inside a small machine H, called the disperse, with spouts a, b, c, d, e, &c. round the sides fixed to it, and the

bottom thereof rests on a center-pin O. In this machine is fixed an upright tube G, with holes at the bottom, and a funnel P on the top to receive a spout of water from a conduit-pipe Q, by the stop-cock R.

This vessel being completed, two or more of them are placed in a reverberatory arch for conveying the intense heat of a strong fire, the flame of which encompasses the iron vessels, and keeps them in a red heat during the time of their use; at which time the cog-wheel I, being turned by proper machines, whirls the disperse about with great velocity, and causes the water in it, by a centrifugal force, to fly through the spouts, against the sides of the red-hot pots, which immediately convert the greatest part thereof into vapour, or elastic steam, which is conveyed by a common pipe and cock to the barrel of the engine, to put the piston in motion; and the waste water is conveyed away at bottom, by means of a pipe at CD, with a valve at D to keep out the air.

Mr. Voulouë's ENGINE, invented for driving the Piles at Westminster-Bridge.

A (plate LI. fig. 1.) the great shaft on which are the great wheel and drum.

B The great wheel with cogs, that turns a trundle-head with a fly to prevent the horses falling when the ram is discharged.

C The drum on which the great rope is wound.

D The follower, with a roller at one corner, in which are contained the tongs that take hold of the ram, and are fastened to the other end of the great rope which passes over the pulley, near the upper end of the guides, between which the ram falls.

E The inclined planes which serve to open the tongs, and discharge the ram.

F The spiral barrel that is fixed to the drum, on which is wound a rope with a counterpoise, to hinder the follower from accelerating, when it falls down to take up the ram.

G The great bolt which locks the drum to the great wheel.

H The small lever which has a weight fixed at one end, passes through the great shaft below the great wheel, and always tends to push the great wheel upwards, and locks the drum to the great wheel.

I The forcing-bar, which passes through the hollow axis of the great shaft, and bears upon the small lever, and has near the upper end a catch, by which the crooked lever keeps it down.

K The great lever which presses down the forcing-bar and discharges the great bolt, at the time the long end is lifted up by the follower.

L The crooked lever, one end of which has a roller, which is pressed upon by the great rope; the other end bears upon the catch of the forcing-bar, during the time the follower is descending.

M The spring that presses against the crooked lever,

H h

level,

lever, and discharges it from the catch of the forcing-bar, as soon as the great rope slackens and gives liberty to the small lever to push up the bolt.

By the horse going round, the great rope is wound about the drum, and the ram is drawn up till the tongs come between the inclined planes, when they are opened, and the ram is discharged.

Immediately after the ram is discharged, the roller which is at one end of the follower, takes hold of the rope that is fastened to the long end of the great lever, and lifts it up; the other end presses down the forcing-bar, unlocks the drum, and the follower comes down by its own weight.

As soon as the follower touches the ram, the great rope slackens, and the spring M discharges the crooked lever from the catch of the forcing-bar, and gives liberty to the small lever to push up the great bolt, and to lock the drum to the great wheel, and the ram is drawn up again as before.

Weaving ENGINE, a machine which may be worked either by wind, water, or a boy or man turning a winch. It is composed of four principal parts; 1st. The serpent *a a* (plate LL. fig. 2.) 2d. The treddles *b b*. 3d. The clapper *c*: and 4thly, the arms *d d d d*.

The serpent is made like the ordinary crank, and by its revolution gives motion to all the moveable parts of the engine. The treddles differ in nothing from the treddles in the common loom, only as they are worked by cords. The clapper *c* is supported between two rails by a cord double twisted, which gives it a spring, and when drawn back by the quadrant of the serpent that hitches in the curved teeth *g g*, causes it to fly forwards with a vibratory motion, and so to beat up the cloth. The arms *d d d d*, and their manner of working, is as follows; *b* is the end of the trigger, to which a cord is fastened which passes through a pulley, and terminates at *i*; *k k* are the weights that draw back the arms; *l* is the hole in which one end of the beam turns; *m* is the web. Fig. 3. shews the manner of conveying the shuttle; N N is a hollow pipe slit underneath, through which the arm L M passes to and fro; O O O O are the supporters. The motion is formed thus: P Q is a kind of trigger, which, though unequally divided by its supporter R, is yet in equilibrio, the end P R being made to weigh exactly as much as R Q. To the end Q of this trigger is tied a cord, which passing through the pulley S, terminates at the extremity of the arm, and is fastened to the little button *m*. At the other extremity of the same arm, to wit, at II, a cord is also tied, which by means of the slit underneath, passes through the pulley 2, and supports the weight 3. At the same end of the arm the box Z, about half the bigness of the shuttle, is fixed, which is enclosed between two little pieces of wood, having at one end of them two teeth Y Z, and at the

other a small whalebone, or steel spring, which naturally inclines the teeth to close, and enter the niches on each side the shuttle, through holes in the box left for that purpose. Across the points I I there goes another cord, which passes through the pulley T, and carries the weight V. This arm thus disposed, goes and comes in the hollow pipe N N, in the following manner: one tooth of the serpent is so contrived as, in turning, to press down the end of the trigger P, and so causes the end Q to rise, which drawing in the cord fastened to the button *m*, makes the arm L M to advance forward; but when the tooth is passed by, then the weight 3, fastened as already said, draws it back again. When the arm is in its natural state, the two little pieces of wood enclose the shuttle by means of the whalebone spring, but when the arm in motion approaches to its opposite, then the cord tied across at II, being a little too short, and the weight V, not being able to pass through the pulley T, the spring is by this means bent back, and the teeth opened to discharge the shuttle, which is immediately received, and grasped by the other arm, and so alternately.

Fig. 4. is the serpent; A A the handle; H H the teeth that press down the trigger; F F the quadrants that work the clapper, as is shewn in the plate; and E E are the elbows, to which the cords are fixed that raise and lower the treddles, as in a common loom.

Fig. 5. is the box, springs, pieces of wood, and teeth *b b*, that enclose the shuttle, represented as opened to discharge it.

Fig. 6. is the shuttle with its niches *a a*.

ENGINE for raising Water by Horse. Mr. Walter Churchman gives the following account (of one he invented) to the Royal Society:

1. In this engine the horses, or other animals, draw horizontally, in a straight line and at right angles, whereby they exert their utmost force; by which means, far greater power is gained from the strength of the horses, &c. than by their going round in a circle: for, by the twist and acuteness of the angles, they draw in towards the center, whereby they waste their power, and likewise shorten their levers; besides, their muscles and tendons from their hinder legs all along their sides to their necks are unequally strained, as the duty is hardest on one side, even though their walk be large: therefore, each of those inconveniences must be attended with pain to the animals when at work, and with a great loss of their strength.

2. A crank does not rise quite $\frac{1}{2}$ of its circle, neither do the regulators or rods, rise or fall perpendicular, but obliquely, whereby an oval figure is formed by the pistons motion in every cylinder, which occasions great friction and a waste of water, and every arm is continually varying in its power while working; as its lever is distant from the perpendicular line, and two of the arms (supposing it a

Fig. 1. Horse Engine for Raising Water by M^r Churchman.

Fig. 2.

M^r Hollands Engine For Raising Water.

hories, or when there is a sufficient force of wind to do their whole duty; *w* the coupling staples with the brasses; *x* the strong catch which confines the great wheel to the frame; *y* the screw or key-band, to confine all close and tight; *z* the cylinders which are screwed together at their ends out of sight; and all the same sort of work chiefly for uniformity in the draught.

In plate LII. *fig. 2.* you have a view of Mr. Holland's engine, at lord Tilney's, for raising water; the description is as follows:

A B, the shaft or axle-tree of the engine, 24 feet long, and 24 inches diameter.

C C C C, an undershot water-wheel, 30 feet diameter; its ladles 18 inches broad, and 12 deep; the fall seven feet.

D E F G, four moveable rings or collars, placed on the shaft, three feet diameter, six inches broad.

H I K L, four forcers, rising and falling alternately, by means of those collars, having four chains fastened to the collars and the tops of the forcers, as represented at **W X Y Z**. The forcer **L** is cut off, to shew the chain more distinct. As the collar **G** moves (with the wheel and axis) half round towards you, the chain *z*, fixed at one end to the lower part of the collar **G** at 2, at its other end at the top of the forcer **L** 1, will pull down the forcer **L** 1 four feet and a half; and, at the same time, a chain **I**, fixed to the head of the forcer **L** 1, and to the head **K**, pulls up the forcer **K** four feet and a half; by which time the collar **G** will have carried its trigger 2 up to the bar *ii*, which will unlock its trigger; and the trigger 3, in the collar **F**, will be brought backward down to **Y**, and there lock the collar **F**. Then, the motion continuing, **K** will be depressed four feet and a half, and the chain **I**, over the pulley **R**, will raise **L** four feet and a half. And thus the two forcers and collars continue rising and falling, moving forwards and backwards, locking and unlocking alternately.

And, in like manner, the other two collars, **D** and **E**, move with their forcers, **H** and **I**.

But, to prevent one collar's moving the backward way, faster than the other moves forwards, there is a gauge-chain **4**, fixed to the collar **G**, passing over another pulley **T**, to the collar **F** at 5, which regulates their motions. These chains are lengthened or shortened by screws, as occasion requires.

M N O P, are four brass cylinders, or pumps, seven feet long; the bores of **M** and **N** are six inches diameter, and those of **O** and **P** seven inches and one quarter; having, at *llll*, each a valve below, which are for taking in the water; and, at *m m m m*, valves in the horizontal parts.

The branches *m n*, *m n*, *m n*, *m n*, communicate the water of their two forcers by *nn*, *nn*, and so it to two pipes, *o n*. These two pipes, *o n*, join together, at a small distance beyond what is represented on the plate, so that the whole water is forced

along one pipe; which makes a jet d'eau of seventy feet, and raises the water to the house above seventy feet perpendicular.

Ninety-five hogheads are forced up, per hour, to the jet d'eau, and forty-seven to the garden.

g, h, are two cisterns, supplied by a pipe *p*, to keep the forcers or pistons always wet.

a b c d e f, is a frame of wood to carry the pullies **Q R S T**, and the bars *ii*, and *kk*.

The water-wheel goes about five times per minute to force the water to the house; and three, when the water is raised eighty feet to the gardens.

One turn of the wheel makes four strokes, viz. each forcer one; **A** is six inches bore, and therefore holds

In $4\frac{1}{2}$ feet	—	4.5 gallons

		100.0
		60 gallons per hour

63)6000.0 (95.3 hogheads per hour.

The half of which is 47.6 nearly.

The method of raising and falling the forcers in this engine is new, and finely contrived.

The locks and collars are so curiously formed, and the chains so nicely adjusted, that there is little or no shock at the taking or leaving, which engines of this kind are too often subject to.

Self-moving ENGINE, a machine invented by a Polish Jesuit; it consists of a pump, whose body *abfg* (plate LIH. *fig. 1.*) is a palm and two fingers breadth in diameter, and four palms in height; the head *defg* is a palm in height; the cylinder *abde* of the body of the pump is two palms and a half in height, of which the piston *c e* fills up one palm; the other palm and half must hold at least five cans of water, each containing three quarts.

The wooden pipe from *fg* to the horizontal pipe *nn* is about thirty-two palms in vertical height.

The author observes, that if the diameter of the mouth of the pipe *bn* be equal to that of the cavity of the pump, and the diameter of the iron rod *hk* be of such size as that the pipe *fgn* shall contain only seventeen cans of water, the machine will be the easier worked, as the water being forced through a passage less straight meets with less resistance.

The diameter of the hole *fg* must be equal to half the diameter *de* of the body of the pump, whence it will be four times straighter than the body of the pump

Ellipse.

Fig. 3. Fire Engine.

Fig. 4. Engine.

Engine.

pump, because circles are to one another as the squares of their diameters.

The machine works in the following manner: The piston *cc* being at the bottom of the pump, the suckers, both of the pump and of the piston, shut by their own weight; whence, by the descent of the bucket *p*, the wheel *mm*, six feet in diameter, is turned, by which means the chain *kz*, by passing round the axis *ll* of the wheel, raises the iron rod *kb*, and the piston *cc*, at which instant the sucker of the pump opens, and gives passage to the water, which is forced into the body of the pump by the weight of the external air; then the counterpoise *v* descends, and so turns the wheel *mm*, round which goes the cord *mm*, which, descending on the other side, raises the bucket.

In proportion as the counterpoise *v* descends, and the bucket *p* is raised, the axle of the great wheel is freed from the twistings of the cord, and so the piston, by its own weight, and that of the iron rod, falls down to the bottom of the body of the pump, and by that means the sucker of the pump shuts, and the five cans of water mount up through the piston by its sucker, which opens above. The same operation is readily performed again, in order to carry that water into the pipe *fgnni*, whence it is discharged through the horizontal pipe *nn* into the basin, which holds at least thirty-two pounds of water. This water falls into the bucket *p*, through the pipe *qr*, whose clap opens (being raised by two cross sticks which are fastened to the cord) and lift up the bar *oy*.

The bucket *p* contains four cans and a half of water; it is two palms in length, ten at the opening, and six inches in depth, when the two long faces uniting, form an angle of 120 degrees; being thus filled, it descends apace, and the bar *no* being depressed, the clap falls and closes the pipe *qr*; and as it descends thirty feet, and the great wheel is ten feet in diameter, it makes an entire revolution; thus the axis *ll* twisting up the chain *kz*, the rod *kb* raises anew the piston *c*, and carries again at least four cans and a half of water into the basin *nq* through the horizontal pipe *nn*.

The bucket, when descended almost to the surface of the water of the well, is raised again by means of the cord *st* which is too short to reach the water, and being for the present discharged of its weight, the piston descends to the bottom of the pump by its own weight and that of the rod *bk*, and the cross stick *so* of the cord of the bucket coming under the bar *oy*, raises it, together with the clap, that the water of the basin *nq* may fall again thro' the pipe *qr* into the bucket *p*, causing it to descend anew, and so maintain a perpetual motion.

There are several other small pieces in this engine, the use of which is easily comprehended by the figure.

ENGINEER, or ENGINEER, properly signifies one skilled in the nature of engines in general; but it is commonly applied to an officer who is appointed to inspect and contrive any attacks, defences, &c. of a fortified place.

ENGLISH, or the ENGLISH-TONGUE, the language spoken by the people of England; and, with some variation, by those of Scotland, as well as part of Ireland, and the rest of the British dominions.

The ancient language of Britain is generally allowed to have been the same with the Gaulic, or French; this island, in all probability, having been first peopled from Gallia, as both Cæsar and Tacitus affirm, and prove by many strong and conclusive arguments; as by their religion, manners, customs, and the nearness of their situation. But now we have very small remains of the ancient British tongue, except in Wales, Cornwall, the islands and highlands of Scotland, part of Ireland, and some provinces of France; which will not appear strange, when what follows is considered.

Julius Cæsar, some time before the birth of our Saviour, made a descent upon Britain, though he may be said rather to have discovered than conquered it; but, about the year of Christ forty-five, in the time of Claudius, Aulus Plautius was sent over with some Roman forces, by whom two kings of the Britons, Codogunus and Caractacus, were both overcome in battle: whereupon a Roman colony was planted at Malden in Essex, and the southern parts of the island were reduced to the form of a Roman province: after that, the island was conquered as far north as the Firths of Dumbarton and Edinburgh, by Agricola, in the time of Domitian; whereupon a great number of the Britons, in the conquered part of the island, retired to the west part, called Wales, carrying their language with them.

The greatest part of Britain being thus become a Roman province, the Roman legions, who resided in Britain for above two hundred years, undoubtedly disseminated the Latin tongue; and the people being afterwards governed by laws written in Latin, must necessarily make a mixture of languages. This seems to have been the first mutation the language of Britain suffered.

Thus the British tongue continued, for some time, mixed with the provincial Latin, till, the Roman legions being called home, the Scots and Picts took the opportunity to attack and harass England: upon which, king Vortigern, about the year 440, called the Saxons to his assistance, who came over with several of their neighbours, and having repulsed the Scots and Picts, were rewarded for their services with the isle of Thanet, and the whole county of Kent: but growing too powerful, and not being contented with their allotment, possessed the inhabitants of all the country on this side

of the fœvern: thus the British tongue was in a great measure destroyed, and the Saxon introduced in its stead.

In the beginning of the ninth century, the Danes invaded England, and getting a footing in the northern and eastern parts of the country, their power gradually increased, and they became sole masters of it in about two hundred years. By this means the ancient British obtained a tincture of the Danish language; but their government, being of no long continuance, did not make so great an alteration in the Anglo-Saxon, as the next revolution, when the whole land, in the year 1067, was subdued by William the Conqueror, duke of Normandy in France: for the Normans, as a monument of their conquest, endeavoured to make their language as generally received as their commands, and thereby rendered the British language an entire medley.

Thus was the ancient British language, in a manner, extirpated by the Romans, Danes, and Saxons, and succeeded by the Saxon, and after that blended with the Norman French. But, besides these, a change in the language has been effected by two other causes. The first is that of commerce; for as the inhabitants of Great-Britain have been for a long series of years greatly addicted to trade, the names of offices, dignities, names of wares, and terms of traffic, have been introduced, and formed according to the genius of our own tongue. The second is that of learning, from which our tongue has received no small improvement; for, as to the Greek and Latin, the learned have, together with the arts and sciences, now rendered familiar among us, introduced abundance, nay almost all the terms of art in the mathematics, philosophy, physic, and anatomy; and we have entertained many more from the Latin, French, &c. for the sake of neatness and elegance: so that, at this day, our language, which, about 1800 years ago, was the ancient British, or Welsh, &c. is now a mixture of Saxon, Teutonic, Dutch, Danish, Norman, and modern French, embellished with Greek and Latin. Yet this, in our opinion, is so far from being a disadvantage to the English tongue, as now spoke (for all languages have undergone changes, and do continually participate with each other) that it has so enriched it, as now to become the most copious, significant, fluent, courteous, amorous, and masculine language in Europe, if not in the world: this, indeed, was Camden's opinion of it in his time, and Dr. Heylin's in his time: if then the English tongue, in the opinion of these learned authors, deserved such a character in their days, how much more now, having since received so considerable improvements from so many celebrated writers.

ENGRAFTING, or GRAFTING, in gardening. See **GRAFTING**.

ENGRAILED, or INGRAILED, in heraldry, a

term derived from the French, *grosly*, hail; and signifying a thing the hail has fallen upon and broke off the hedges, leaving them ragged, or with half rounds, or semi-circles, struck out of their edges.

ENGRAVING, the art of cutting on wood, metals, precious stones, &c. figures, landscapes, letters, &c.

ENGRAVING on Wood. See the article **CUTTING in Wood**.

ENGRAVING on Copper, the making, correspondently to some delineated figure or design, such concave lines, on a smooth surface of copper, either by cutting or corrosion, as render it capable, when charged properly with any coloured fluid, of imparting by compression an exact representation of the figure or design to any fit ground of paper or parchment.

The method by which engraving is at this time performed, is of three kinds: by the graver or tool alone, which is in common language the only kind called engraving: by corrosion with aqua-fortis, which is generally called etching: and by covering the surface of a copper-plate with lines, in such manner, that the whole would produce the effect of black in an impression; and then scraping or bur-nishing away part of the lines, so as to cause the remainder to have the same effect as if they had been cut on the even surface, according to the delineation of any figure or design; which last kind is called scraping in mezzotinto. See **ETCHING** and **MEZZOTINTO**.

Engraving with the tool was the kind originally practised, and it is yet retained for many purposes. For though the manœuvre of etching be more easy, and other advantages attend it, yet where great regularity and exactness of the stroke or lines are required, the working with the graver is much more effectual; on which account it is more suitable to the precision necessary in the execution of portraits; as there every thing the most minute must be made out and expressed, according to the original subject, without any licence to the fancy of the designer in deviating from it, or varying the effect either by that masterly negligence and simplicity in some parts, or those bold sallies of the imagination and hand in others, which give spirit and force to history painting.

ENGRAVING on precious Stones, is the representing of figures, or devices, in relief, or indented, on divers kinds of hard polished stones.

In this branch of engraving, they make use either of the diamond, or emery.—The diamond, which is the hardest, and most perfect of all precious stones, is only cut by itself, or with its own matter. See **DIAMOND**.

As to rubies, emeralds, hyacinths, amethysts, garnets, agats, and other of the softer stones, they are cut on a leaden wheel, moistened with emery and

and water; and polished with tripoli, on a pewter-wheel. Lapis, opal, &c. are polished on a wooden wheel.

To fashion and engrave vases of agat, crystal, lapis, or the like, they have a kind of lathe, like that of the pewterers, excepting, that whereas the latter is to hold the vessels which are to be wrought with proper tools; the former generally holds the tools, which are turned by a wheel, and the vessel held to them to be cut and engraved, either in relievo, or otherwise; remembering, from time to time, to moisten the tools with diamond dust and oil, or at least emery and water.

To engrave figures or devices on any of these stones, when polished, such as medals, seals, &c. they use a little iron wheel, the two ends of whose axes are received within two pieces of iron placed upright, as in the turner's lathe, to be brought closer, or set farther apart, at pleasure. At one end of one of the axes are fitted the proper tools, being kept tight by a screw. Lastly, the wheel is turned by the foot, and the stone applied by the hand to the tool; and thus shifted and conducted, as occasion requires.

The tools are generally of iron, sometimes of brass. As to their form it is various, but generally bears some resemblance to chisels, gouges, &c. some have small round heads like buttons, others like ferrels, to take the pieces out; others flat, &c. These tools are not applied directly against the stone, but, as it were, sidewise; thus wearing, and, as it were, grinding off the substance: and still, whether it be figures, or letters, or characters, the manner of application is the same. The tools, as above observed, are to be frequently moistened with diamond dust, and oil of olives. When the stone is engraven, they polish it on a wheel of brushes, made of hogs bristles, with tripoli. For the larger and less delicate works, they have copper or pewter tools on purpose to polish the ground, or plain parts, with tripoli, &c. which they apply after the same manner as those wherewith the graving is performed.

ENGRAVING on Steel is chiefly employed in cutting punches for coins, medals, &c.

The methods of engraving, with the instruments, &c. are the same for coins, as for medals and counters: all the difference consists in their greater or less relievo; the relievo of coins being much less considerable than that of medals; and that of counters still less than that of coins.

The engraver in steel usually begins with punches, or punchions, which are in relievo, and serve for making the creux, or cavities of the matrices, and dies. Though, sometimes, he begins immediately with the creux; but it is only when the intended work is to be cut very shallow. The first thing is to design his figures; then he moulds

them in white wax, of the size and depth required; and from this wax he graves his punch.

This punch is a piece of steel, or at least of iron and steel mixed; on which, before they temper or harden it, the intended figure, whether a head, or a reverse, is cut, or carved in relievo. The instruments used in this graving in relievo, which are much the same as those wherewith the finishing of the work in creux is effected, are of steel. The principal are gravers of divers kinds, chisels, flatters, &c. When the punch is finished, they give it a very high temper, that it may the better bear the blows of the hammer, wherewith it is struck, to give the impression to the matrice.

What they call matrice, or matrix, is a piece of good steel of a cubic form, called also a die; whereon the relievo of the punch is struck in creux. It is called matrix, because, in the cavities or indentures thereof, the coins, or medals, seem formed, or generated, as animals are in the matrix of their mother. To soften this steel, that it may more easily take the impressions of the punch, they make it red hot; and, after striking the punch thereon in this state, they proceed to touch up or finish the strokes and lines, where, by reason of their fineness, or the too great relievo, they are any thing defective, with some of the tools abovementioned.

The figure thus finished, they proceed to engrave the rest of the medal, as the mouldings of the border, the engrailed ring, letters, &c. all which, particularly the letters and graining (or engrailment) are performed with little steel punches, well tempered and very sharp. And that, as they sometimes make use of punchions to engrave the creux of the matrix, so, on some occasions, they make use of the creux of the matrix to engrave the relievo of the punch.

To see and judge of the engraving in creux, divers means have been devised to take impressions therefrom as the work proceeds. Sometimes they make use of a composition of common wax, turpentine, and lamp black; which, always retaining its softness, easily takes the impression of the part of the graving it is applied to. But, this only serving to shew the work piece-meal, they have had recourse to other ways, to shew the whole figure. The first, by pouring melted lead on a piece of paper, and clapping the matrix thereon: the second, with melted sulphur, managed the same way: and the third, proper only where the graving is shallow, by laying a piece of soft paper on the graving, and over the paper a leaf of lead, when, giving two or three blows with a hammer on the lead, the paper takes the impression of the work.

When the matrix is quite finished, they temper it, rub it well with pumice-stone, and clean out the stone again with a hair-brush; and, lastly, polish it with oil and emery.

INGUICHE, in heraldry, is said of the great mouth of a hunting-horn, when its rim is of a different colour from that of the horn itself.

ENHARMONIC, in the ancient music, one of their genera or kinds of music, so called from its superior excellence; though wherein it consisted, says Mr. Malcolm, is hard to say: it was allowed by all to be so very difficult, that few could ever practise it.

Others say, it is a species of music, the modulation whereof proceeds by intervals less than semitones; as the semitone minor, enharmonic diesis, and third major.

ENIXUM, among chemists, a kind of neutral salt, generated of an acid and an alkali.

The sal enixum of Paracelsus, is the caput mortuum of spirits of nitre with oil of vitriol, or what remains in the retort after the distillation of this spirit, being of a white colour, and pleasing acid taste.

ENMANCHE, in heraldry, is when lines are drawn from the center of the upper-edge of the chief to the sides, to about half the breadth of the chief; signifying sleeved, or resembling a sleeve, from the French *manche*.

ENNEAGON, in geometry, a figure consisting of nine angles, and as many sides.

The word is derived from the Greek *ennea*, nine, and *gonia*, an angle.

ENNEAHÆDRIA, in natural history, the name of a genus of spars.

The word is derived from the Greek *ennea*, nine, and *hædra*, a side.

The bodies of this genus are spars, composed of nine planes, in a triangular column, terminated at each end by a triangular pyramid.

ENNEANDRIA (from *ennea*, nine, and *andros*, male) the name of the ninth class in the Linnæan system of botany, and comprehends those plants whose flowers are hermaphrodite and furnished with nine stamina in each.

To this class belong the flowering rush, Brazilian-plumb, laurel, rhubarb, &c.

ENNERIS, in the naval architecture of the ancients, a galley or vessel with nine tiers of oars. See the article **GALLEY**.

ENS, among metaphysicians, denotes entity, being, or existence: this the schools call *ens reale*, and *ens positivum*, to distinguish it from their *ens rationis*, which is only an imaginary thing, or exists only in the imagination.

ENS, among chemists, imports the power, virtue, and efficacy, which certain substances exert upon our bodies.

ENS VENERIS, the sublimate of equal quantities of dulcified calx of vitriol, and the dried flowers of sal ammoniac, a small proportion of which turns a large one of the infusion of galls black: it is red, saline, and astringent, and said to be an excellent medicine in distempers arising from a weakness of the solids, as the rickets, and the like.

ENSIFORM, in general, something resembling a sword; thus we find mention of ensiform leaves, ensiform cartilage, &c.

The word is compounded of the Latin, *ensis*, a sword, and *forma*, resemblance.

ENSIGN, in the military art, a banner, under which the soldiers are ranged, according to the different companies or parties they belong to.

ENSIGN is also the officer that carries the colours, being the lowest commissioned officer in a company of foot, subordiinate to the captain and lieutenant.

ENSIGN, in naval affairs, a sort of banner or flag hoisted on a pole called the ensign-staff, over the stern of a ship.

It is used to distinguish the ships of different nations from one another, as also the different squadrons of a fleet from each other. See **FLAG** and **SIGNAL**.

ENTABLATURE, or **ENTABLEMENT**, in architecture, is that part of an order of a column, which is over the capital, and comprehends the architrave, frieze, and cornice.

The entablature is also called the trabeation, and seems borrowed from the Latin, *trabs*, a beam; though others derive it from *tabulatum*, a ceiling, because the frieze is supposed to be formed by the ends of the joists which bear upon the architrave.

It is different in different orders; for, notwithstanding it consists of the three before-mentioned divisions in all, yet these parts are made up of more or fewer particular members or subdivisions, according as the order is more or less rich. Vignola makes the entablature a quarter of the height of the whole column in all the orders. In the Tuscan and Doric, the architrave, frieze, and cornice, are all the same height. In the Ionic, Corinthian, and Composite, the whole entablature being of fifteen parts, five of these go the architrave, four to the frieze, and six to the cornice. See the articles **TUSCAN**, **DORIC**, &c.

ENTABLATURE, in masonry, is used sometimes to denote the last row of stones on the top of the wall of a building, on which the timber and covering rest. This is often made to project beyond the naked of the wall, to carry off the rain.

ENTAIL, in law, is a free estate entailed; that is, abridged and limited to certain conditions prescribed by the donor or grantor. See the articles **FEE**, **RECOVERY**, and **TAIL**.

ENTE, in heraldry, a method of marshalling more frequent abroad than with us, and signifying grafted or ingrafted.

ENTELECHIA, *εντελεχεια*, a word used by Aristotle to express the soul, and which, not occurring in any other author, has given the commentators upon that philosopher great trouble to discover its true meaning.

ENTEROCELE, in surgery, is a kind of swelling, in which the intestine falls into the groin or scrotum.

The word is Greek, and derived from *εντερον*, an intestine, and *κηλη*, a hernia, tumour, or rupture.

ENTERO-EPIPOCELE, in surgery, is a kind of rupture in which the intestines and omentum, or caul, fall down together into the scrotum.

The word is derived from the Greek *εντερον*, an intestine, and *επιπλοον*, the caul.

ENTERO-EPILOMPHALUS, in surgery, is a rupture caused by the intestine and caul falling down through the navel.

The word is formed from the Greek *εντερον*, a gut, *επιπλοον*, the caul, and *ομφαλος*, the navel.

This is a disorder common to women with child.

ENTERO-HYDROMPHALUS, in surgery, is when the tumour is caused by the gut and water swelling out at the navel.

The word is formed from the Greek *εντερον*, a gut, *υδωρ*, water, and *ομφαλος*, the navel.

ENTEROLOGY, a treatise on the bowels, which generally includes the contents of the three cavities, the head, breast, and belly.

The word is Greek, and derived from *εντερον*, a gut, and *λογος*, a discourse.

ENTERPLEADER, in law, signifies the discussing or trial of point, incidentally falling out, before the principal cause can be determined.

ENTERSOLE, in architecture, a kind of little story, sometimes called a mezzanine, contrived occasionally at the top of the first story, for the convenience of a ward-robe, &c.

ENTERTAINMENT, in a theatrical sense. See the article *FACE*.

ENTHUSIASM, a transport of the mind, whereby it is led to think and imagine things in a sublime, surprising, and yet probable manner.

The word is Greek, *ενθουσιασμος*, and derived from *ενθουσιαζω*, to be agitated with divine raptures.

ENTHUSIASM, in a religious sense, implies a transport of the mind, whereby it fancies itself inspired with some revelation, impulse, &c. from heaven.

ENTHUSIAST, a person possessed with enthusiasm.

ENTHYMEME, *ενθυμημα*, among logicians, denotes a syllogism, perfect in mind, but imperfect in the expression, by reason one of the propositions is suppressed, as being easily supplied by the understanding of those with whom we discourse: as for example, *Every man is mortal; therefore every king is mortal*; where the minor proposition, *every king is a man*, is omitted, as being sufficiently known.

There is a particular elegance in the enthymeme form of arguing, as leaving somewhat to the exercise and invention of the mind; for which reason it is very frequent, as well in common conversation, as in the most polite writers. It not only shortens

discourse, and adds a certain strength and liveliness to our reasoning, but also gives the reader a pleasure not unlike that the author himself feels in composing. By this means we are put upon exerting ourselves, and seem to share in the discovery of what is proposed to us.

ENTIER, in the manege, a resty horse that not only refuses to turn, but also resists the hand.

ENTIERTY, or ENTIERTIE, among lawyers, implies the whole of a thing, in contradistinction to a moiety: thus a bond, damages, &c. are said to be intire, when they cannot be apportioned.

ENTIRE TENANCY, in law, is when the sole possession is in one person, in contradistinction to several tenancy, which is a joint, or common possession of two or more.

ENTITIVELY, and ENTIETY, among metaphysicians. See *ENS*.

ENTOYER, in heraldry, denotes a border charged wholly with things without life: it seems to be a corruption of the French *entour*, round about.

ENTREPAS, in the manege, a broken pace or going that is neither walk nor trot, but has somewhat of an amble.

ENTROCHUS, in natural history, the name of a genus of fossils, of a very regular figure and structure, supposed, by many authors, to be lapides sui generis, and stones in their native state. They are, however, in reality, the fossil remains of some marine animal, probably either of the echinus, or of the star-fish kind, filled, like the fossil species of the echini, with a plated spar.

ENTRY, in law, signifies taking possession of lands or tenements, where a person has a right so to do. It is also used for a writ of possession.

Bill of ENTRY, in commerce. See *BILL*.

ENVELOPE, in fortification, a work of earth, sometimes in form of a simple parapet, and at others, like a small rampart with a parapet; it is raised sometimes on the ditch, and sometimes beyond it.

Envelopes are often made to enclose a weak ground, where that is practicable, with single lines, to save the great charge of horn-works and tenails, or where there is not room for such large works. Some give the name of fillon, counterguard, conserve, and lunette, to envelopes raised in the moat.

ENVIRONNE, in heraldry, signifies surrounded with other things: thus, they say, a lion environné with so many bezants. See the article *BEZANT*.

ENUMERATION, an account of several things, in which mention is made of every particular article.

ENUMERATION, in rhetoric, a part of peroration, in which the orator, collecting the scattered heads of what has been delivered throughout the whole, makes a brief and artful relation, or recapitulation thereof.

K k

ENVOY, a person deputed to negotiate some affair with any foreign prince or state.

ENURNY, in heraldry, is applied to a border charged with beasts.

ENVY, in ethics, is defined to be an uneasiness of the mind, caused by the consideration of a good we desire, obtained by one we think less worthy of it than ourselves. See the article PASSION.

EPACTS, in chronology, the excesses of the solar month above the lunar synodical month, or of the solar year above the lunar year of 12 synodical months.

The common lunar year of 12 synodical lunations consists of but 354 days, 8 hours, 48 min. 57 sec. whereas the solar or tropical year consists of 365 days, 5 hours, 48 min. 57 sec. it is plain therefore that the solar year exceeds the lunar by 10 days, 21 hours, 00 min. 19 sec. and in the space of about 33 years, the beginning of the lunar year will have moved through all the variety of seasons, whence it is called the moveable lunar year; and this form of the year is at this time used by the Turks and Arabs.

Hence, as the Julian year is 365 days, 6 hours, and the lunar year, as above, only 354 days, 8 hours, 48 min. 57 sec. the annual epact will be 10 days, 21^h 11^m 22^s; that is, nearly 11 days. Consequently, the epact of 2 years is 22 days; of 3 years, 33 days; or rather 3, since 30 days is an embolismic, or intercalary month.

Thus, the epact of 4 years is 14 days, and so of the rest; and at the end of every 19th year, the epact becomes 30 or 0; consequently the 20th year the epact is 11 again; and so the cycle of epacts expires with the golden number, or lunar cycle of 19 years, and begins again with the same.

Again, as the new moons are the same, that is, as they fall on the same day every 19 years, so the difference between the lunar and solar years is the same every 19 years: and because the said difference is always to be added to the lunar year, in order to adjust, or make it equal to the solar year, hence the said difference respectively belonging to each year of the moon's cycle is called the epact of the said year, that is, the number to be added to the said year, to make it equal to the solar, the word being formed from the Greek *επαγω, induco, intercalo*.

Upon this mutual respect between the cycle of the moon, and the cycle of the epacts, is founded this rule for finding the epact belonging to any year of the moon's cycle. Multiply the year given of the moon's cycle into 11, and if the product be less than 30, it is the epact sought; if the product be greater than 30, divide it by 30, and the remainder of the dividend is the epact according to the Julian account.

But as a synodical month or space of time contained between the moon's parting from the sun, at a conjunction. and returning to him again, is 29

days, 12 hours, 44 min. and 6 sec. it follows, that 235 lunations are made in 6939 days, 16 hours, 43 min. 30 sec. but in 19 Julian years are 6939 days, 18 hours; and, consequently, the new moons, after 19 Julian years, will not return to the same hour of the day, but will happen 1 hour, 16 min. 30 sec. sooner.

And therefore, because the new moons do not return at the same time of the day that they did 19 years before; but in 312 years they will anticipate one day; we must, in order to find the epact according to the Gregorian calendar, make proper allowance for the anticipation since the Nicene council, which was held in 325.

To do this, divide the centuries of the proposed year by 4; let the quotient be multiplied by 43, and the remainder by 17; to the sum of these products add 86, and divide the whole by 25. Let the quotient (neglecting fractions) be subtracted from 11 times the prime or golden number, then will the remainder, rejecting thirties, be the epact required.

To find the epact until the year 1900, the following rule will serve:

Subtract 1 from the prime or golden number, multiply the remainder by 11, and, rejecting thirties as before, the remainder will give the epact.

Example. Let it be required to find the epact for the year 1765.

$$\begin{array}{r} \text{By the first rule} \quad 4) \frac{17}{4} \left(\begin{array}{l} 17 \\ 43 \\ 172 \\ 17 \\ 86 \end{array} \right. \\ \hline 25) 275 \mid 11 \end{array}$$

$$\begin{array}{r} \text{G N}^{\circ} = 18 \\ \hline 11 \\ 18 \\ \hline 18 \\ 198 \\ \hline 11 \\ 30) 187 \mid 6 \\ \hline 180 \\ \hline \therefore 7 = \text{the epact.} \end{array}$$

By the second rule

$$\begin{array}{r} \text{G N}^{\circ} = 18 \\ \hline 11 \\ 17 \\ \hline 11 \\ 17 \\ \hline 17 \\ 30) 187 \mid 6 \\ \hline 180 \\ \hline 7 = \text{the epact as before.} \end{array}$$

EPANORTHOSIS, in rhetoric, a figure by which a person corrects, or ingeniously revokes, what he just before alledged, as being too weakly expressed, in order to add something stronger and more conformable to the passion with which he is agitated.

EPARER, in the manege, signifies the flinging of a horse, or his jerking and striking with his hind legs. See **YERK**.

EPAULE, in fortification, denotes the shoulder of a bastion, or the place where its face and flank meet, and form the angle called the angle of the shoulder. See the article **BASTION**.

EPAULEMENT, in fortification, a work raised to cover sidewise, is either of earth, gabions, or fascines, loaded with earth. The epaulements of the places of arms for the cavalry, at the entrance of the trenches, are generally of fascines mixed with earth.

EPAULEMENT also denotes a mass of earth, called, likewise, a square orillon, from its figure, raised to cover the cannon of a cazemate, and faced with a wall.

It is likewise used for any work, thrown up to defend the flank of a post, or other place.

EPEMBOLE, in rhetoric, the same with **parembole**. See the article **PAREMBOLE**.

EPENTHESIS, in grammar, the interposition or insertion of a letter or syllable in the middle of a word, as *alutium*, for *alutim*; *relligio*, for *religio*; *induperator*, for *imperator*, &c.

EPHA, or **EPHAE**, in Jewish antiquity, a measure for things dry, containing 1.0961 of a bushel. See **MEASURE**.

EPHEDRA, sea-horse-tail, in botany, a low shrubby plant, which sends forth a few short branches, rising about two feet high, with many protuberant joints, from whence come out several narrow rusty leaves, which continue green throughout the year. It is of the diœcia class, bearing male and female flowers on different plants; the male are amentaceous, destitute of a corolla, but the perianthium contains seven stamina, coalescing in a subulated column; the female flower is also apetalous, but consists of a quintuplex calyx, with two ovated germina, which afterwards becomes two baccated seeds acutely oval, convex on one side and plain on the other.

EPHEMERA, in medicine, the name of a species of fever, continuing the space of one day, or sometimes more; for the medical writers express themselves by *ephemera simplex*, *vel plurium dierum*.

This species of fever has this peculiar to it, that the pulse is at first large, but as it becomes afterwards moderately quick and frequent, so it is equal, soft, and regular, as in a natural state. The urine undergoes little or no change, nor is the disorder preceded by a loathing of food, a spontaneous lassitude

of the body, disturbed sleep, preternatural yawning, or horror; but it seizes the patient suddenly, and afflicts him with no other symptoms than a pain of the head and stomach, a nausea, heat, and restlessness. The persons most subject to this fever, are young men who have much blood, and feed heartily, and such as have had any habitual discharge of blood stopped upon them, whether natural, as in the hæmorrhoidal or menstrual discharges, or artificial, such as frequent bleeding, cupping, and the like; and those who have thrown their blood into violent emotions by the too free use of spirituous liquors, too violent exercise, unusual watchings, long stay by large fires, a sudden repression of sweats by cold water, or by violent passions, particularly anger. In the treatment of this fever, the proper course is to temperate the violent motions of the blood with nitrous and the fixed antimonial medicines, and occasionally with gentle acids. Sweat is to be promoted. Nitre, crabs-eyes, &c. may be prescribed in small doses every three or four hours; and towards night, sodorifics should be joined to these, such as the contrayerva-root, or the like. The ephemera, properly so called, differs in nothing, except the time of its duration, from that which commonly lasts four days.

EPHEMERA MALIGNA is also a term by which some authors have called the fudor anglicanus, or malignant diary fever, which generally destroyed the patient in twenty-four hours. See the article **SUDOR ANGLICANUS**.

EPHEMERA, the day-fly, in zoology, a genus of flies belonging to the neuroptera order, and so called from their living only one day and a night: they are about the size of the lesser house-flies, and have two gibbous protuberances on the top of the head, resembling eyes; add to this, that the tail is furnished with hairs, and the antennæ are short.

Of this genus there are several species, distinguished by their different colours, and the number of hairs in their tail; some have two, and others three.

EPHEMERIDES, in astronomy and chronology, an appellation given to such books that contain the longitudes and latitudes of the planets, their passages over the meridian, and their declination; their conjunction among themselves, and with the fixt stars; the occultations of the principal fixt stars by the moon; the eclipses of Jupiter's satellites, and, in general, all the calculations which are necessary for a knowledge of the actual state of the heavens, and for facilitating astronomical observations.

In France there are several ephemerides published, but those calculated by De la Caille and De la Land are in the greatest esteem, and mostly used by astronomers in England, being the best that have appeared of the kind in any nation. However, in

a short time, we may expect to see one far superior to these, which will be published in England for the year 1767.

The honourable commissioners of the Board of Longitude, from various reports that have been made to them by persons well skilled in navigation and astronomy, of the great usefulness of such a book, have taken it into consideration, and have come to a resolution to employ five persons, at the government's expence, to calculate a nautical ephemerides for the use of sailors in general, and by which (with the help of the general table, discovered and now making by Mr. Witchell) they may with ease determine the longitude of a ship at sea by only observing the distance of the moon from a fixed star, or from the sun, with a Hadley's quadrant.

EPHIPPUIM, in anatomy, the same with the cella turcica, being a part of the os sphenoides. See the article SPHENOIDES.

EPHOD, in Jewish antiquity, one part of the priestly habit; being a kind of girdle which, brought from behind the neck over the two shoulders, and hanging down before, was put cross the stomach, then carried round the waist, and made use of as a girdle to the tunic.

There were two sorts of ephods, one of plain linen for the priests, and the other embroidered for the high-priest: of this last Moses gives an ample description. It was composed of gold, blue, purple, crimson, and twisted cotton. Upon part of it, which passed over the shoulders, were two large precious stones, one on each shoulder: upon these were engraven the names of the twelve tribes, six upon each stone.

The ephod was peculiar to the priesthood, and thought essential to their character; it being the opinion of the Jews, that no worship, true or false, could subsist without a priesthood and ephod.

EPHORI, *εφοροι*, in Grecian antiquity, magistrates established in ancient Sparta to balance the regal power.

EPIC, or HEROIC POEM, a discourse formed upon a story partly real and partly feigned, representing some glorious and fortunate action, that is distinguished by a variety of wonderful, yet probable and pleasing events, and delivered in verse by way of narration, in a sublime and flowing style; to form the manners, and inflame the mind with the love of virtue.

What distinguishes an epic from a dramatic poem, is, its being a narration that comes immediately from the poet, and is not represented as a tragedy by persons introduced for that purpose.

The chief things to be considered in an epic poem are, first, the fable, that is, the form, and artful representation of the action, which is the matter of the poem; and as the action is more or less perfect, so is the fable. The action in an epic poem, as well

as in tragedy, must be one, not all the actions of a person's life; because the mind is better satisfied with the contemplation of a single object that is easily understood, than when it is perplexed with a variety, and lost in confusion. And on this principal action must all the episodes or under-actions so depend, as to become different, yet useful, members of the same body, and contribute to its support. It must likewise be entire, that is, complete in all its parts, or, as Aristotle describes it, have a beginning, a middle, and an end. Nothing should go before, be intermixed with, or follow after this main action, but what is related to it: nor should any single step be omitted in that just and regular process, which it must be supposed to take from its origin to its consummation. The epic action ought also to be great, that it may strike us with awe, and be suitable to the dignity of the princes, heroes, and illustrious persons, who are supposed to be speaking and acting in the poem. It should likewise be interesting, that it may engage our passions and affections; and entire, that the mind may be wholly satisfied. As to its duration, it is not circumscribed within any limited time; but the warmer and more violent the action is, the shorter must be its continuance. Thus the Iliad, whose subject is the anger of Achilles, contains only forty-seven days: but the Æneid, whose hero is of a quite different character, takes up a much longer time.

The manners and sentiments fall under the same rule as those of tragedy: and as to the diction, it ought to be perspicuous, but at the same time figurative, noble, and sublime. See TRAGEDY.

The moderns seem to mistake that part of the epic and tragedy which contain the wonderful, confounding it with improbable, and using the two words promiscuously. If it was really so, the wonderful would be always faulty; for that is always so which is improbable. The great art is a just temperament and mixture of both, to make it natural and probable. Scarce any of the poets but Virgil had the art, by the preparation of incidents, to manage the probability in all the circumstances of an epic poem. Homer is not altogether so scrupulous and regular in his contrivances: his machines are less just, and all his measures, to save the probability, are less exact. Lastly, the sovereign perfection of an epic poem, in the opinion of Aristotle, consists in the just proportion and perfect connection of all the parts. It is not sufficient that all be grand and magnificent in an epic poem, but all must be just, uniform, and proportionable, in the different parts that compose it.

This is all that can be observed most essential to an epic poem: little need be said about the machinery, which, among the ancient heathens, was the agency of their false gods, and of angels and demons among us christians: its beauty and magnificence is well known. The dignity of an epic poem would scarce be kept up without it, especially since the

the marvellous depends on it. The versification of epic poetry, among the Greeks and Romans, consisted of hexameters, a sort of verse peculiar to the epic, that when it is used upon other occasions, it is called heroic verse. Our English verse comes nearest to it both in gravity and majesty, but at how great a distance? See the article **HEXAMETER**.

An epic or heroic poem is the best and most perfect kind of poetry; it is the greatest work which the soul of man is capable of performing; and here it is the utmost bounds are set to human composition. All the nobleness and the elevation of the most perfect genius can hardly suffice to form such a one as is requisite for an heroic poet, the difficulty of finding together fancy and judgment, heat of imagination and sobriety of reason, precipitation of spirit and solidity of mind, renders this character so very rare: it requires great images, and yet a greater wit to form them. There must be a judgment so solid, a discernment so exquisite, such perfect knowledge of the language in which he writes, such obstinate study, profound meditations, and vast capacity, that scarce whole ages can produce one genius fit for an epic poet: even among the ancients themselves, if we except Homer and Virgil, we shall scarce find one that is truly an epic poet.

EPICARPIUM, in ancient pharmacy, denotes a remedy applied in form of a plaster to the wrists: it consisted of penetrating ingredients, as garlic, onion, camphor, &c.

EPICEDIUM, *επιτάφιος*, in ancient poetry, a poem rehearsed during the funeral solemnity of persons of distinction. See the article **NENIA**.

EPICERASTICA, *επικραστικά* from *μερᾶννυμι*, to mix or temperate. Medicines which temperate or obtund the acrimony of the humours, and mitigate the uneasy sensation of the parts thence arising.

EPICHIREMA, *επιχρημα*, in logic, a mode of reasoning, which comprehends the proof of one or both the premises of a syllogism, before the conclusion is drawn.

EPICOENE, in grammar, a term applied to nouns, under the same gender and termination, mark indifferently the male and female species.

EPICUREAN PHILOSOPHY, the doctrine or system of philosophy maintained by Epicurus and his followers.

Epicurus, the Athenian, one of the greatest philosophers of his age, was obliged to Democritus for almost his whole system, notwithstanding he picked himself upon deriving every thing from his own fund. He wrote a great number of books, which are made to amount to above 300. Though none of them are come down to us, no ancient philosopher's system is better known than his, for which we are most indebted to the great Lucretius, Diogenes Laertius, and Tully.

His philosophy consisted of three parts, canonical, physical, and ethereal. The first was about the canons, or rules of judging. The censure which Tully passes upon him for his despising logic, will hold true only with regard to the logic of the stoics, which he could not approve of, as being too full of nicety and quirk. Epicurus was not acquainted with the analytical method of division and argumentation, nor was he so curious in modes and formation as the stoics. Soundness and simplicity of sense, assisted with some natural reflections, was all his art. His search after truth proceeded only by the senses, to the evidence of which he gave so great a certainty, that he considered them as an infallible rule of truth, and termed them the first natural light of mankind.

In the second part of his philosophy, he laid down atoms, space, and gravity, as the first principles of all things: he did not deny the existence of a God, but thought it beneath his majesty to concern himself with human affairs: he held him a blessed, immortal being, having no affairs of his own to take care of, and above meddling with those of others. See **ATOMICAL PHILOSOPHY**.

As to his ethics, he made the supreme good of man to consist in pleasure, and consequently supreme evil in pain. Nature itself, says he, teaches us this truth, and prompts us from our birth to procure whatever gives us pleasure, and avoid what gives us pain. To this end he proposes a remedy against the sharpness of pain: this was to divert the mind from it, by turning our whole attention upon the pleasures we have formerly enjoyed: he held that the wife man must be happy, as long as he is wise; that pain, not depriving him of his wisdom, cannot deprive him of his happiness.

There is nothing that has a fairer shew of honesty than the moral doctrine of Epicurus. Gassendus pretends, that the pleasure in which this philosopher has fixed the sovereign good, was nothing else but the highest tranquility of mind in conjunction with the most perfect health of body: but Tully, Horace, and Plutarch, as well as almost all the fathers of the church, give us a very different representation: indeed the nature of this pleasure, in which the chief happiness is supposed to be seated, is a grand problem in the morals of Epicurus. Hence there were two kinds of Epicureans, the rigid and the remiss: the first were those who understood Epicurus's notion of pleasure in the best sense, and placed all their happiness in the pure pleasures of the mind, resulting from the practice of virtue. The loose or remiss Epicureans, taking the words of that philosopher in a gross sense, placed all their happiness in bodily pleasures, or debauchery. Thus we have the whole mystery of this celebrated doctrine. It was innocent in expression, but criminal in thought; it had a beautiful outside, but it was all corruption within. These loose philosophers

took up a seeming austerity to disguise their secret indulgence, and all their schemes of morality were but for many veils for their immoral behaviour.

EPICYCLE, is a small circle whose center is in the circumference of a greater or a small orb, which being fixed in the large orb of a planet, is carried along with its motion, and yet by its own peculiar motion carries the body of the planet round its proper axis. The epicycle was of great use in the Ptolemaic astronomy for solving the different phases and phenomena that happen among the planets, but it is quite omitted in the copernican system.

EPICYCLOID, is a curve generated by a point taken in the periphery of a circle that rolls or revolves upon the periphery of another circle either within or without.

Case I. If the circle ABC remains immoveable while AMDP (plate LIII. fig. 2.) runs on its circumference, then every epicycloid, as $AeQgb$, is called simple or ordinary, and its following properties are evident.

1°. Let the velocities of that circle be ever so unequal, the arc AB (which call the base of the epicycloid) is equal to the circumference AMDP.

2°. If the arc OI, similar to the arc AB, be divided into four equal parts, at the points E, F, G, the center O will have come to the point E, when the point A has described a fourth part of its track in returning to the circle ABC: the same happens at the points F, G, I, where the center of the circle AMDP is found at the end of each fourth part of its return to the circumference ABC. Therefore, if through the point F be drawn a radius prolonged, it will give the point Q for the vertex of the epicycloid; and the part QT of this radius will be its axis, which is equal to the diameter of the circle AMDP. And if from the point E as a center, with a radius equal to OA, an arc of a circle be described towards O, it meets the epicycloid in the point e, where the point A was when the center O was in E. In the same manner the point A will also be found to have been in g, when the center was in G; whence it follows, that the arc Ae was described while the point A retrograded in describing a part of its inferior semi-circle; and the arc eQg was described while the point A described its upper semi-circle with a direct motion: lastly, the arc gB was described while the point A retrograded in the other part of its inferior semi-circle.

3°. The epicycloid is bisected in the vertex Q; and the legs QeA, QgB, of the curve are equal, and similarly posited with respect to the axis TQ.

4°. The arcs Ae, gB, bend towards the axis TQ; because the retrograde motion of the point A carries them in that direction: but they do not return into themselves, as in fig. 3, because the path OI of the center A being in every revolution greater than the arc AB, which is equal to the circumference AMDP, the motion of that center in the di-

rection OI draws the point A towards K, more than its retrograde motion about the center O carries it an opposite direction.

5°. The describing point A, in passing from the leg QgB to the leg BK of the next epicycloid, makes an angle at B: for the point describing the last leg of the epicycloid AQB, the instant it comes to B, immediately rises again into the first leg of the other epicycloid BKC, and describes no space between the legs.

6°. The point A viewed from S, appears always direct, but the velocity seems to accelerate all along the leg AQ, to be greatest at the vertex Q, and then to diminish along the leg QgB, so as to become nothing in the point B; then again it accelerates in the leg BK.

Case II. If, while the circle AMDP rolls on ABC, the latter should also turn on its center S, in the same direction ABC: (fig. 4.) or in general, if the center of the circle AMDP advances in the circle QI, with a greater velocity than the point A has in revolving in the circle AMPD; then the epicycloid described during the revolution of the point A, would be lengthened; and evidently have the following properties:

1°. Since all the points of a simple epicycloid would advance towards C, although the circle ABC was at rest; then, if ABC advances also in the same direction, the velocity of the describing point must be greater in that direction, and consequently make those spaces longer; so that the base AB of the epicycloid must be equal to the sum of the circumference AMDP, and that arc the circle ABC has described during a return.

2°. If the motions of the two circles are uniform, the points E, F, G, dividing OI into four equal parts, will determine, as above, the epicycloidal arcs Ae, eQ, Qg, gB, answering to the motion of the point A in the inferior and superior parts of its circle; the axis TQ will be equal to the diameter AD, and the legs QeA, QgB, are equal, and similarly posited in respect to the axis.

3°. The greater the velocity of the circle ABC, the less the arcs Ae, gB, bend towards TQ.

4°. The describing point does not form an angle in passing from the leg QgB into the leg BK, but makes a curve in B, which is more obtuse as the velocity of the circle ABC is greater: for this velocity makes the point A descend more obliquely along the leg QgB; and when arrived at B, makes it describe a small space on ACB, before it ascends into the leg BK, so that the passage is through a curve gBK.

5°. The point A viewed from the point S, is always direct; and its velocity accelerates from A to Q; then diminishes from Q to B; where it appears to be nothing, or only equal to the velocity of the circle ABC.

Case III. If, during the time of the return of A

to the circle ABC, this circle should also turn on its center in an opposite direction; or in general, if the center of the circle AMPD advances in the circle OFI, with less velocity than that wherewith the point A moves in the circle AMPD; then the epicycloid would become shortened. This case might be subdivided into several others, but not to make this theory needlessly complex, let only the retrograde velocity of the circle ABC be supposed less than that of the point A in its circle AMPD. Now on this hypothesis,

1°. If the circle ABC (fig. 3.) had remained immoveable, none of the points of the epicycloid would have retrograded; but as ABC retrogrades, its motion must augment the velocity of the point A in the inferior semi-circle where it retrogrades, and diminish it in the upper semi-circle where it is direct. Hence it follows, that the extent of the epicycloid will be diminished in the direction ABC, its basis becoming equal to the difference between the circumference of the circle AMPD, and the arc which the circle ABC has described during the return of the point A.

2°. These two motions being uniform, the arcs Ae , eQ , Qg , gB , will, as above, be found answering to the upper and inferior parts of the circle AMPD; the axis $TQ=AD$, and the legs QeA , QgB , equal and in similar positions in respect of the axis TQ .

3°. The arcs Ae , gB , answering to the retrograde motion of the point A, are more curved towards the axis TQ , in proportion as the velocity of the circle ABC is greater; and at the point B the arc must turn inwards; because then the point A moves contrary to the tendency towards C, by the sum of both motions.

4°. The passage of the point A through the point B is made by a curve gBm , returning towards itself: for when the point A has described the leg QgB , and arrives at B, the retrograde velocity of the circle ABC causes it to describe a small space before the point A ascends by the leg BmK .

5°. The point A viewed from the point S, appears sometimes direct, sometimes retrograde, and sometimes immoveable, or stationary. For the tangents Sm , Sn , SA , Sy , being drawn from the point S, shew that the point A appears direct in describing the arc $nQgt$, all the points of that arc being directed towards C: when the point A is in the tangent St , it must appear stationary, that is, tending neither towards C nor O, during the time of describing the arc of the curve which coincides with the tangent: afterwards the point A seems retrograding in the arc tBm , that is, in the arc comprehended between the two tangents; and in the point m it again seems stationary: lastly, it appears direct in the arc mKy , till it becomes stationary in y ; then retrogrades as before, and so on. Therefore the point A during every revolution in its circle, ap-

pears twice stationary, once direct, and twice retrograde.

6°. The velocity of the point A must appear equal to nothing in the stationary points; then it appears accelerated until A comes to the vertex of the curve, where the velocity seems greatest; because the arcs then described are directly exposed to the eye; then it diminishes from these points to the next stationary point.

7°. The greater the velocity of the circle ABC, the greater is the arc of retrogradation tBm .

Corol. Therefore in these sorts of motions, the nature of the epicycloid generally depends on the relation of its base AB to the circumference of the circle where the describing point is.

Schol. If, in the second and third cases, the motion of these circles had not been uniform, the epicycloid would then have been less regular, and the axis TQ not in the middle between the legs QeA , QgB ; nor the legs equal or in like positions; one would be longer than the other, according as the combination of the velocities urged more on one side than on the other: but the epicycloid would retain nearly the same figure; that is, it would always have a curvature towards B, disposed in the same manner as in fig. 3 and 4.

From this general theory such conclusions may be drawn as are applicable to the phenomena of the motions of the planets, according to the order in which they are ranged in the solar system.

EPIDEMIA, *επιδημία*, in Grecian antiquity, festivals kept in honour of Apollo and Diana, at the stated seasons when these deities, who could not be present every where, were supposed to visit different places, in order to receive the vows of their adorers.

The festival took its name *epidemia*, from *επι*, among, and *δημος*, people; on account of the imaginary presence of those deities among the people.

EPIDEMIA is also used for the private feasts, or rejoicings, on account of the safe return of a friend from a voyage or journey.

EPIDEMIC, among physicians, an epithet of diseases, which, at certain times, are popular; attacking great numbers at or near the same time.

EPIDEMIC diseases differ from those called endemic. See the article ENDEMIC.

We must remark, says the celebrated Boerhaave, that though every particular disease of the fluids; in various epidemical constitutions, appear, to inattentive observers, the same with regard to their names, signs, and their consequences in some measure, yet the same diseases, appearing in one epidemical constitution, differ exceedingly from those produced in another, with respect to their obscure natures; their appearances not observable, except by the judicious; the various times of their increase, state, coction, crisis, effect, event, and method to be pursued for the cure. Hence it is evident, that they require a different administration of the non-naturals.

naturals, different treatment and medicines: this variety, however, in epidemical distempers, is so obscure, that physicians have not yet been able to deduce it from any abuse of the non-naturals: and yet there are many circumstances which make it highly probable, that the causes reside in the air, but depend more upon the inexplicable variety of exhalations contained therein, which, by their mixture with the fluids of the body, or their stimulus, injure the human machine, than upon any change in the sensible qualities thereof. But it is very surprising, that these epidemical disorders should be principally propagated by contagion, received from one by another person unaffected.

Upon the invasion of any unknown epidemical distemper, the physician will receive some information with respect to the cure, first, by reducing the distemper to some more known species, which it most resembles.

Secondly, by observing its tendency at the vernal and autumnal equinoxes, at which season it is generally most prevalent.

Thirdly, by attending to the spontaneous phenomena which precede, accompany, or follow, the death or recovery of the patient, and the better or worse state of the disorder.

Fourthly, by diligently remarking the benefit or injury received, from whatever the patients are unavoidably obliged to do; whatever is taken into, or discharged out of the body.

Fifthly, by comparing the cases of a great many patients labouring under the distemper at the same time.

Sixthly, by abstaining from all remedies which are dubious, which exagitate and induce a considerable change in the humours, and thereby obscure the genus of the disease.

From these circumstances, duly attended to, the curative indication arises.

EPIDERMIS, in anatomy, the same with the cuticle. See the article **CUTICLE**.

EPIDIDYMUS, in anatomy, the name by which some call the two bodies more usually known by that of parastatæ. See the article **PARASTATÆ**.

EPIGASTRIC REGION, a part or subdivision of the abdomen. See **ABDOMEN**.

EPIGASTRIC VESSELS, the arteries and veins belonging to the epigastric region; the former being branches of the coeliac artery, and the latter of the iliac veins. See **ARTERY** and **VEIN**.

EPIGLOTTIS, in anatomy, one of the cartilages of the larynx, or wind-pipe. It is often of the shape of an ivy-leaf, and joined to the thyroide cartilage; over which it appears erect, immediately behind the root of the tongue; to which it is also connected by its middle ligament by two lateral ones to the cornua of the os hyoides, and by two posterior ones to the arytenoide cartilage. In the act of

swallowing it covers the glottis, or aperture of the larynx, and prevents any thing getting into it. See the articles **LARYNX** and **GLOTTIS**.

EPIGRAM, in poetry, a short poem, or composition in verse, treating of one thing only, and whose distinguishing characters are brevity, beauty, and point.

The word epigram signifies inscription; for epigrams derive their origin from those inscriptions placed by the ancients on their statues, temples, pillars, triumphal arches, and the like; which, at first, were very short, being sometimes no more than a single word, but afterwards, increasing their length, they made them in verse, to be the better retained by the memory. This short way of writing came at last to be used upon any occasion or subject; and hence the name of epigram has been given to any little copy of verses, without regard to the original application of such poems.

Its usual limits are from two to twenty verses, though sometimes it extends to fifty; but the shorter the better it is, and the more perfect, as it partakes more of the nature and character of this kind of poem: besides, the epigram, being only a single thought, ought to be expressed in a little compass, or else it loses its force and strength.

The beauty required in an epigram, is an harmony and apt agreement of all its parts, a sweet simplicity, and polite language.

The point is a sharp, lively, unexpected turn of wit, with which an epigram ought to be concluded. There are some critics, indeed, who will not admit the point in an epigram, but require the thought to be equally diffused through the whole poem, which is usually the practice of Catullus, as the former is that of Martial. It is allowed, there is more delicacy in the manner of Catullus, but the point is more agreeable to the general taste, and seems to be the chief characteristic of the epigram.

This sort of poem admits of all manner of subjects, provided that brevity, beauty, and point, are preserved; but it is generally employed either in praise or satire.

Though the best epigrams are said to be such as are comprised in two or four verses, we are not to understand it as if none can be perfect which exceed those limits. Neither the ancients or moderns have been so scrupulous with respect to the length of their epigrams; but, however, brevity in general is always to be studied in these compositions.

EPILEPSY, *επιληψία*, in medicine, the same with what is called the falling-sickness, from the patient's falling suddenly to the ground.

Sometimes this disease comes upon the patient unawares; but it more frequently gives notice of its approach, by a lassitude of the whole body, a heavy pain in the head, with some disturbance of the senses, unquiet sleep, unusual dread, dimness of sight, and a noise in the ears: in some there is a
vio-

violent palpitation of the heart, a puffing or inflation of the breast, difficult respiration, a murmuring noise in the belly, foetid stools, a flux of the urine, and refrigeration of the joints: in others, there is a sensation as it were of cold air, ascending from the extreme parts towards the brain and heart. At length, falling senseless to the ground, the thumbs are shut up close in the palms of the hands, and are with difficulty taken out; the eyes are distorted or inverted, so as nothing but the whites appear: all sensation is suspended, inasmuch that no smell, no noise, nor even pinching of the body, is able to bring them to themselves: they froth at the mouth with a hissing kind of noise; the tongue is lacerated, or torn by the teeth, and there is a shaking or trembling of the joints. However, in different patients the symptoms vary; for sometimes, instead of convulsive motions, the limbs are all stiff, and the patient is as immoveable as a statue: in infants the penis is erected; and in young men, there is an emission of the semen, and the urine sometimes streams out to a great distance. At last there is a remission of the symptoms, and the patients come to themselves after a longer or shorter interval; then they complain of a pain and heaviness of the head, and a lassitude of all their joints.

These fits usually return on certain days, or age of the moon, but especially about the new or full moon; in women, chiefly about the time of menstruation; and as to the prognostics, they generally leave the patient about the time of puberty.

As to the cure, in adults, or grown persons, it is extremely difficult; but in children, it is just the reverse. Blisters laid on the back part of the head are of great use a little before the fit is expected; which may the more certainly be foreknown, as this disease is influenced by the moon. The most proper medicines to correct the juices seem to be native cinnabar, and wild valerian root; a dram of which may be taken morning and evening for three or four months, and afterwards two or three days before the new and full moon. Or, two scruples of the powder of wild valerian root, mixed with one of that of native cinnabar, may be taken morning and evening. Ambergris and musk are also accounted excellent.

It must not however be forgot, that this disease owes its origin to so many different causes, and is bred in so many different constitutions of the body, that the same remedy which succeeds in one case, often fails in another; and, therefore, different medicines are to be tried, especially in adults. In case of a plethora, bleeding in the ankles will be proper. If the humours be in fault, cathartics, issues, cauteries, and blisters must be used. If in children it proceeds from gripes, or the breeding of teeth, nothing is better than to cleanse the belly by milk clysters, with a little Venice-soap dissolved in them.

Some epileptic powder with cinnabar, or extract of rhubarb, and made into an electuary with syrup of roses and manna, may likewise be given in proper doses.

During the fit, too free an use of volatiles, spirituous liquors, and strong smells, are hurtful, as causing the humours to flow too much to the head. The best method is to place the patient in an erect posture, and to rub the hands and feet pretty briskly; and the best drink is pure water, which will mitigate, if not cure, the symptoms.

When the disease is caused by external violence, or extravasations of humours in the head, cinnabar reduced into an impalpable powder, and given in large doses with other cephalics and diaphoretics, has a kind of specific virtue.

According to Dr. Cheyne, a milk-diet will cure the most inveterate epilepsy. Milletoe is also said to cure it, as sure as the bark does an intermitting fever: its dose, to grown people, is half a dram or more, in powder, to be taken every sixth hour, drinking after it a draught of a strong infusion of the same plant; and if to every ounce of the powder, a dram of asa-foetida be added, the medicine will be still more effectual. Cinnabar of antimony is also greatly celebrated for the cure of this disease, and may be taken from four grains to a scruple, in conserve of rosemary-flowers. If the disease is inveterate, some advise to give the following pills for a month, viz. Take castor and gum ammoniac, of each eight grains; wild valerian-root, half a scruple; salt of tartar, seven grains; and as much of the tincture of castor as is sufficient to form them into pills, one of which makes a dose. On every seventh day, a cathartic should be given; and sometimes, instead of the castor and gum, filings of steel may be substituted.

A decoction of guaiacum, or sassafras, taken twice a day, six or eight ounces at a time, and continued for thirty or forty days, is also said to cure the epilepsy; especially if male piony-root, or the like, be added.

EPILOBIUM, French willow, in botany, a genus of plants whose flower consists of four roundish patent petals somewhat emarginated, with eight filaments which are subulated and alternately shorter, these are topped with oval compressed obtuse antheræ; the fruit is a very long, cylindraceous, striated capsule, with four cells, and contains a number of oblong seeds crowned with down.

This genus includes the chamænerion of Tournefort.

EPILOGUE, in oratory, the end or conclusion of a discourse, ordinarily containing a recapitulation of the principal matters delivered. See **PERORATION**.

EPILOGUE, in dramatic poetry, a speech addressed to the audience after the play is over, by one of the principal actors therein, usually containing

taining some reflections on certain incidents in the play, especially those in the part of the person that speaks it.

EPIEDIUM, barren-wort, in botany, a plant with a creeping root, from which arise many stalks about nine inches high, each of which is divided into three branches, which are again subdivided into three lesser, upon each of these are a stiff cordated leaf ending in a point, of a pale green on the upper side but grey underneath; below the first division of the stalk come out the flowers, which are cruciform of a redish colour with yellow stripes on the border, the stamina are four subulated filaments topped with oblong erect bivalvular antheræ. The fruit is an oblong acuminate pod of one cell, containing many oblong seeds.

EPINICION, in the Greek and Latin poetry, denotes a poem or composition on occasion of a victory obtained. It also signifies a rejoicing, or festival, on account of a victory.

EPIPHANY, a Christian festival, otherwise called the Manifestation of Christ to the Gentiles, observed on the sixth of January, in honour of the appearance of our Saviour to the three magi, or wise men, who came to adore him and bring him presents. The feast of Epiphany was not originally a distinct festival, but made a part of that of the nativity of Christ, which being celebrated twelve days, the first and last of which were high or chief days of solemnity, either of these might be called Epiphany, as that word signifies the appearance of Christ in the world.

EPIPHONEMA, in rhetoric, a sententious exclamation, containing a lively remark placed at the end of a discourse; such is that of Virgil:

*Fas omne abrupit, Polydorum obtruncat, & auro
Vi potitur. Quid non mortalia pectora cogis
Auri sacra fames?*

And that of Lucretius, lib. i.

Tantum religio potuit suadere malorum!

This figure closes a narration in a very advantageous manner, deeply impresses the thing related upon the memory of the reader, and leaves him well pleased with the sense and sagacity of his author.

EPIPHORA, in medicine, a preternatural de-fluxion of the eyes, when they continually discharge a sharp serous humour, which excoriates the cheeks. The cure is performed by a derivation of the offending humour elsewhere, by bleeding, cupping, blisters, purges, &c. The acrimony is likewise to be corrected by bitter chalybeate wine: sometimes wine drank alone will perform the cure; after which, astringent topics are to be made use of. See the article **RHEUM**.

If an epiphora has been of long standing, it is difficult to be cured, and often degenerates into a

fistula lachrymalis. See the article **FISTULA LACHRYMALIS**.

EPIPHYLOSPERMOUS, from *φυλλον*, a leaf, and *σπερμα*, seed, among botanists, are those plants which bear their seeds on the back of their leaves, such as maidenhair, fern, &c. and are the same as capillary plants.

EPIPHYSIS, in anatomy, a bony substance, or as it were a lesser bone affixed to a larger or principal bone, by the intervention of a cartilage. In young people these epiphyses are not continuous to the principal bone, but are only connected by the intermediate cartilage, and hence they are called appendages to the bones. It is to be observed of epiphyses, 1. That they are all cartilaginous in infants; and though they afterwards grow hard, yet they never arrive at the true density of a bone. 2. That most of them degenerate into apophyses in adults. 3. That they do not grow along the plain surface of the bone, but unequally, or by a mutual ingress with the body of it.

The use of the epiphyses is very different in adults and in infants: 1. In adults they seem to serve the bones which contain large quantities of marrow, by way of operculum, that this soft matter may not run out. 2. They are of service to the articulators, rendering the motions more easy, as well as more determinate. 3. They make the whole bone lighter than it would be, if their place were supplied by absolute bony matter. 4. They increase the power of the muscles along the tendons, by means of their prominences. 5. They add to the size of the places destined for receiving the insertions of the muscles. 6. They give a firmer cohesion to the ligaments which serve in the articulations, and allow an entrance to the blood-vessels. The uses of the epiphyses in infants are, 1. That by means of their yielding softness, they may give way to the compression in the uterus, and suffer the whole bulk to be more folded together than otherwise it could, so that it may lie in a smaller compass. 2. That they may give way to the elongation and growth of the bones. 3. That they may prevent the frequent fractures, which would otherwise unquestionably happen to children from their falls, and the other accidents they are liable to.

EPIPOCELE, in medicine, is a kind of hernia, or rupture, in which the omentum subsides into the scrotum. The cure consists principally in a reduction of the tumour, by returning the omentum again into the abdomen, and in securing the parts from a relapse by a truss or bandage. See **HERNIA** and **ENTEROCÉLE**.

EPIPLOIS, in anatomy, a term applied to the arteries and veins distributed through the substance of the epiploon or caul: thus, the dextera epiplois is a branch of the right side of the cæliac artery, and the sinistra epiplois and gastro-epiplois are terms by which anatomists call branches from the left side of the

the cæliac artery. See the articles *CÆLIAC* and *ARTERY*.

EPIPLOOMPHALON, *ἐπιπλομφαλον*, in medicine, a hernia umbilicalis, proceeding from the omentum falling into the region of the umbilicus or navel. See the article *EXOMPHALUS*.

EPIPLOON, the same with what is otherwise called omentum. See *OMENTUM*.

EPIPHLOSARCOMPHALUS, in surgery, a kind of exomphalus. See the article *EXOMPHALUS*.

EPISCOPACY, the quality of episcopal government, or that form of church discipline, wherein diocesan bishops are established distinct form, and superior to, priests or presbyters. See *BISHOP*.

EPISCOPAL, something belonging to bishops. See the articles *BISHOP* and *EPISCOPACY*.

EPISCOPALIANS, in church history, an appellation given to those who prefer the episcopal government and discipline to all others.

EPISODE, *ἐπεισοδιον*, in poetry, a separate incident, story, or action, which a poet invents, and connects with his principal action, that his work may abound with a greater diversity of events: though, in a more limited sense, all the particular incidents whereof the action or narration is compounded, are called episodes. See the articles *EPIC* and *TRAGEDY*.

The episode, in its original, was only something rehearsed between the parts of the chorus, or ancient tragedy, for the diversion of the audience. Episodes serve to promote the action, to illustrate, embellish, and adorn it, and carry it to its proper period. Episodes are either absolutely necessary, or very requisite. All episodes are incidents, though all incidents are not episodes; because some incidents are not adventitious to the action, but make up the very form and series of it. Examples will clear up this distinction: the storm in the first *Æneid* of Virgil, driving the fleet on the coast of Carthage, is an incident, not an episode, because the hero himself and the whole body of his forces are concerned in it; and so it is a direct and not a collateral part of the main action. The adventures of Nisus and Euryalus, in the ninth *Æneid*, are episodes, not incidents, i. e. not direct parts of the main action.

It is particularly by the art of episodes that the great variety of matter which adorns a poem is brought into the principal action: but though the episodes are a kind of digression from the subject, yet they ought to have a natural relation to the principal action, never be far fetched, and must be handled with judgment, to avoid confusion and burdening the subject with too much action. Without this restriction the episode is no longer probable, and there appears an air of affectation which becomes ridiculous. Aristotle calls all those fables episodic, which abound in episodes not necessarily nor properly connected with each other.

The most natural episodes are the properest to circumstantiate the principal actions, namely, the causes, the effects, the beginnings, and the consequences of it. Homer and Virgil have shewn their principal art in this particular: the action of the *Iliad* and that of the *Æneid* were in themselves exceeding short, but are so beautifully lengthened and diversified by the intervention of episodes, that they make up an agreeable story, sufficient to employ the memory without overcharging it. See the article *EPIC*.

Our noble poet Milton has excelled in this art; he has no other episodes than what naturally arise from the subject, and yet his poem of *Paradise Lost* is filled with a multitude of astonishing incidents. Those great actions, the battle of the angels, and the creation of the world, are by way of episode to this noble poem. With the like art, and in the same manner, in that part of it which regards the fall of man, he has related the fall of those angels who are his professed enemies; besides the many other beauties of such an episode, its running parallel with the great action of the poem, hinders it from breaking unity so much as another episode would have done, that had not so great an affinity with the principal subject.

EPISPASTIC, in medicine, a topical remedy, which being applied to the external parts of the body, attracts the humours to that part.

EPISTLE, *ἐπιστολή*, denotes the same with a missive letter; but is now chiefly used in speaking of ancient writings, as the epistles of St. Paul, epistles of Cicero, epistles of Pliny, &c. See the article *LETTER*.

EPISTOLARY, something belonging to an epistle.

EPISTROPHE, in rhetoric, a figure wherein that which is supposed of one thing is strongly affirmed of another: thus, "Are they Hebrews? so am I. Are they Israelites? so am I. Are they of the seed of Abraham? so am I," &c.

EPISTYLE, in the ancient architecture, a term used by the Greeks for what we call architrave, viz. a massive piece of stone or wood, laid immediately over the capital of a column. See *ARCHITRAVE* and *COLUMN*.

EPITAPH, a monumental inscription, which generally contains some eulogium of the virtues and good qualities of the deceased, and has a turn of seriousness and gravity adapted to the nature of the subject. The elegance of epitaphs consists in a nervous and expressive brevity; and sometimes are closed with an epigrammatic point. In these compositions no mere epithet, properly so called, should be admitted; for here illustration would impair the strength, and render the sentiment too diffuse and languid. Words that are synonymous are also to be rejected.

Though

Though the true characteristic of the epitaph is seriousness and gravity, yet we find many that are jocose and ludicrous; some likewise have true metre and rhyme, while others are between prose and verse, without any certain measure, though the words are truly poetical, and the beauty of this last sort is generally heightened by an apt and judicious antithesis.

EPITASIS, in ancient poetry, the second part or division of a dramatic poem, wherein the plot, entered upon in the first part, or protasis, was carried on, heightened and worked up till it arrived at its state or height, called catastasis.

In the epitalis, accidents, as they are called by the moderns, arise; all things are in confusion, and involved in doubts and difficulties. Vossius says, the epitalis is contained in the second, sometimes in the third and fourth, but very rarely any part of it in the fifth act: but Dr. Trapp says, that there is no act to which the epitalis is not suitable; nay, that some of it ought always to be in the fifth act.

It is the epitalis that supports the weight and burden of the poem; upon it the crisis of the action chiefly turns. This division of tragedy is laid aside in the modern drama, instead of which plays are divided into acts.

EPITASIS, in medicine, the increase of a disease, or beginning of a paroxysm, particularly in a fever. See FEVER.

EPITHALAMIUM, in poetry, a nuptial song, or composition, in praise of the bride and bridegroom, praying for their prosperity, for a happy offspring, &c.

EPITHEM, in pharmacy, a kind of fomentation, or remedy of a spirituous aromatic kind, applied externally to the regions of the heart, liver, &c. to strengthen and comfort the same, or to correct some intemperature thereof.

EPITHET, in poetry and rhetoric, an adjective expressing some quality of a substantive to which it is joined; or such an adjective as is annexed to substantives by way of ornament and illustration, not to make up an essential part of the description. Nothing, says Aristotle, tires the reader more than too great a redundancy of epithets, or epithets placed improperly; and yet nothing is so essential in poetry as a proper use of them. The writings of the best poets are full of them, especially Virgil.

EPITOME, in literary history, an abridgement, or summary of any book, particularly of a history. See ABRIDGEMENT.

EPITRITUS, in prosody, a foot consisting of three long syllables and one short. Of these, grammarians reckon four kinds: the first consisting of an iambus and spondee, as *salūtātes*: the second, of a trocheus and spondee, as *conciātes*: the third, of a spondee and an iambus, as *cōmūnicātes*: and the fourth, of a spondee and trocheus, as *incantātes*. See the articles SPONDEUS, TROCHEUS, &c.

EPITROPE, in rhetoric, a Greek term for the same figure which the Latins call *concessio*. See the article CONCESSION.

EPIZEUXIS, in rhetoric, a figure which repeats the same word, without any other intervening: such is that of Virgil, *nunc, nunc, insurgite remis*.

EPOCHA, or EPOCHE, in chronology, signifies some remarkable occurrence from whence some nations date and measure their computation of time.

As in the heavens there are certain points from which the astronomers begin their computations of the planets motions, so also there must be certain points, or instants of time, from which, as from roots, all calculations must begin: and all memorable actions are disposed and recorded according to the series of years which follow from that root. These roots are called Epochs, or *Æras*, from which we generally count our years and times. The most famous, best known, and most used by us, is that which is reckoned from the nativity of our Lord Jesus, which begins at the kalends of January that immediately followed his birth.

The epocha of the creation, which is much noted, yet about it there are great controversies among chronologists; some affirming that the world was created 3950 years before the birth of Christ; others again say, that at the birth of Christ the age of the world was 3983 years. The Greek church, and the emperors of the East, used an epocha of the creation which was much more ancient, and makes the world to have been created 5509 years before the coming of Christ.

Among the prophane authors, the most ancient epocha is that of the Olympiads, which begun at the summer of the year 777 preceding the birth of Christ, and on the kalends of July.

The epoch of Rome, or of the building of the city, is not long after the Olympiads, and there are two of them, the Varronian, and Capitoline; according to the first, the city was built the year before Christ 753; according to the other, it was in the year 752.

The æra of Nabonassar has always been famous among the astronomers, and began on the sixth of February of the Julian year carried backward, and before Christ 747. And because that day was then the first of the Egyptian year, Ptolomy, and after him Copernicus, computed the motion of the stars according to that æra by Egyptian years; for the Egyptian year is very convenient for astronomical calculations, it being interrupted by no intercalary days.

After this we have another epocha of the death of Alexander the Great, the 324th year before Christ, on the twelfth of November; which was then the first day of the Egyptian year. Theon, Albategnius, and some others, have computed from thence according to the Egyptian year. Between the two æras of Nabonassar and of the death of Alexander, there

Fig. 7. Equation of Time.

Fig. 8. Equation of Time.

Fig. 10.

there are precisely 424 Egyptian years. The Abifines reckon by another æra, which is called the Æra of the Martyrs, or of Dioclesian. The Turks and Arabians reckon by an æra, which they call the Hegira, which takes its beginning from the flight of Mahomet. The Persians have likewise an epoch which they call Isfdegird; all which are explained by the chronologists. But the Julian period seems to be the most useful and convenient of all, it including almost all other æras within it, and it is a period of 7980 years; which number is composed by the multiplication of the three numbers, 15, 19, and 28. The first is the cycle of the indiction; the second is the Metonic cycle of the moon; and the third is the cycle of the sun. And the first year of this period was that wherein all these three cycles began together.

The following table gives the year of the several æras, and reduces them to the years of the Julian period, and to the years before or after the birth of Christ.

	Years before Christ.	Years of the Julian Period.
The creation of the world according to the Greek emperors	5508	
The common æra of the creation	3950	765
The beginning of the Olympiads	776	3938

EPODE, in lyric poetry, the third or last part of the ode, the ancient ode being divided into strophe, antistrophe, and epode. See ODE, &c.

The epode was sung by the priests, standing still before the altar, after all the turns and returns of the strophe and antistrophe, and was not confined to any precise number or kind of verses.

The epode is now a general name for all kinds of little verses that follow one or more great ones, of what kind soever they be; and in this sense a pentameter is an epode after an hexameter. And as every little verse, which being put after another, closes the period, is called epode; hence the sixth book of Horace's Odes is entitled, *Liber Epodon*, Book of Epodes, because the verses are all alternately long and short, and the short ones generally, though not always, close the sense of the long one.

EFOMIS, in anatomy, a muscle, otherwise called deltoides. See DELTOIDES.

EPOPOEIA, in poetry, the story, fable, or subject treated of in an epic poem. See FABLE.

The word is commonly used for the epic poem itself. See EPIC POEM.

EPULONES, in Roman antiquity, ministers who assisted at the sacrifices, and had the care of the sacred banquet committed to them.

EQUABLE, an appellation given to such motions as always continue the same in degree of velocity, without being either accelerated or retarded.

EQUAL, a term of relation between two or more things of the same magnitude, quantity, or quality.

EQUALITY, that agreement between two or more things, whereby they are denominated equal.

The equality of two quantities, in algebra, is denoted by two parallel lines placed between them: thus, $4+2=6$, that is, 4 added to 2, is equal to 6.

EQUANITY, in ethics, denotes that even and calm frame of mind and temper, under good or bad fortune, whereby a man appears to be neither puffed up, or overjoyed with prosperity; nor dispirited, soured, or rendered uneasy by adversity.

EQUANT, ÆQUANT, or Circle of EQUALITY, in astronomy, is a circle used in the Ptolemaic system to account for the eccentricity of the planets, &c.

EQUATION, in algebra, is a proposition wherein one quantity is declared equal to another, or where one expression of any quantity is declared equal to another expression of the same quantity: as when we say $\frac{2}{3}=\frac{4}{6}$; where $\frac{2}{3}$ is said to possess one side of the equation, and $\frac{4}{6}$ the other.

An affected quadratic equation is an equation consisting of three different sorts of quantities; one wherein the square of the unknown quantity is concerned, another wherein the unknown quantity is simply concerned, and a third wherein it is not concerned at all: as if $xx-2x=3$; supposing x to be an unknown quantity.

If either the term wherein the simple power of x is concerned, as $-2x$, or that which is called the absolute term, to wit, 3, be wanting, the equation is still a quadratic equation, though incomplete. Some indeed there are, who rank this latter sort of equations under the denomination of simple equations; and so shall we, upon account of their easy resolution; though properly speaking, a simple equation is that wherein some simple power of the unknown quantity is concerned, all others being excluded: as if $3x=6$; $2x+3=4x-5$, &c.

The use of these equations is for representing more conveniently and more distinctly the conditions of problems, when translated out of common language into that of algebra. As for example; let it be proposed to find a number with the following

N n

pro-

property, to wit, that $\frac{2}{3}$ of it with 4 over, may amount to the same as $\frac{7}{12}$ of it with 9 over: here, putting x for the unknown quantity, the condition of this problem, when translated out of common language into that of algebra, will be represented by the following equation, to wit, $\frac{2x}{3} + 4 = \frac{7x}{12}$

+ 9: for $\frac{2}{3}$ of x , that is, $\frac{2}{3}$ of $\frac{x}{1}$ is $\frac{2x}{3}$; therefore $\frac{2x}{3} + 4$ signifies $\frac{2}{3}$ of x with 4 over; and since this expression according to the problem, amounts to the same with the other, to wit, $\frac{7x}{12} + 9$; hence it is that we pronounce them equal to one another.

Now since in the foregoing equation, as well as in almost all others arising immediately from the conditions of problems themselves, the unknown quantity is embarrassed and entangled with such as are known, the way to disengage it from such known quantities, so that itself alone possessing one side of the equation, may be found equal to such as are entirely known on the other, that is, in the present case, to determine the value of the unknown quantity x , is what is commonly called the resolution of an equation: for the effecting of which, several axioms and processes are required; some whereof, namely such as most frequently occur, I shall here put down; the rest I shall take notice of occasionally, as they offer themselves.

Of the resolution of simple EQUATIONS.

Axiom I. Whenever a fraction is to be multiplied by a whole number, it will be sufficient to multiply only the numerator by that number, retaining the denominator the same as before. Thus $\frac{4}{3}$ multiplied into 2, gives $\frac{8}{3}$, for the same reason that 4 shillings multiplied into 2 gives 8 shillings: thus in the first example following, $\frac{7x}{12}$ multiplied into

3, gives $\frac{21x}{12}$.

Axiom II. But if the whole number into which the fraction is to be multiplied, be equal to the denominator of the fraction, then throw away the denominator, and the numerator alone will be the product. Thus the fraction $\frac{a}{b}$ multiplied into b ,

gives $\frac{ab}{b}$ or a : thus in the first example, $\frac{2x}{3}$ multiplied into 3, gives $2x$; and $\frac{21x}{12}$ multiplied into 12 gives $21x$.

Axiom III. If the two sides of an equation be multiplied or divided by the same number, the two products, or quotients, will still be equal to each other. Thus in the first example, where $\frac{2x}{3} + 4$

$= \frac{7x}{12} + 9$; if both sides of the equation be multiplied into 3, we shall have $2x + 12 = \frac{21x}{12} + 27$;

and if again this last equation be multiplied into 12, we shall have $24x + 144 = 21x + 324$.

Axiom IV. If a quantity be taken from either side of an equation, and placed on the other with a contrary sign, which is commonly called transposition, the two sides will still be equal to each other. Thus if $7 + 3 = 10$, transpose + 3, and you will have $7 = 10 - 3$; thus if $7 - 3 = 4$, transpose - 3, and you will have $7 = 4 + 3$; thus if (as in the first example) $24x + 144 = 21x + 324$, transpose $21x$, and you will have $24x - 21x + 144 = 324$, that is, $3x + 144 = 324$; and if again in this last equation you transpose 144, you will have $3x = 324 - 144 = 180$.

Transposition therefore, as it is here delivered, is nothing but a general name for adding or subtracting equal quantities from the two sides of an equation; in which case it is no wonder, if the sums or differences still continue equal to each other. As for instance, in this equation $a - b = c$, transposing $-b$ we have $a = c + b$: and what is this after all, but adding b to both sides of the equation? for if b be added to $a - b$, the sum will be a ; and if b be added to c , the sum will be $c + b$; therefore $a = c + b$: again, in the equation $a + b = c$, transposing $+b$ we have $a = c - b$, which is nothing else but subtracting b from both sides of the equation.

The 1st process. If, when an equation is to be resolved, fractions be found on one, or both sides, it must be freed from them by multiplying the whole equation into the denominators of those fractions successively.

The 2d process. After the equation is thus reduced to integral terms, if the unknown quantity be found on both sides the equation, let it be brought by transposition to one and the same side, viz. to that side, which after reduction will exhibit it affirmatively.

The third process. After this, if any loose known quantities be found on the same side with the unknown, let them also be brought by transposition to the other side of the equation.

The 4th process. If now the unknown quantity has any coefficient before it, divide all by that coefficient, and the equation will be resolved.

The 5th process. If the whole equation can be divided by the unknown quantity, let such a division be made, and the equation will be reduced to a more simple one. Thus in the 16th example you have $615x - 7xx = 48x$; divide the whole equation by x , and you will have $615 - 7x = 48$. In the 13th example you have $\frac{42x}{x-2} = \frac{35x}{x-3}$; divide the whole

by x , which is done by dividing only the numerators of

of the two fractions, and you will have $\frac{42}{x-2} = \frac{35}{x-3}$.

The 6th process. If at last the square of the unknown quantity, and not the unknown quantity itself, appears to be equal to some known quantity on the other side of the equation, then the unknown quantity must be made equal to the square root of that which is known. Thus in the 14th example we have $x = 36$; therefore $x = 6$, and not 18: in the 15th, we have $x = 64$; therefore $x = 8$, the square root of 64, and not 32, its half.

Examples of the resolutions of simple EQUATIONS.

This preparation being made, I shall now give some examples of the resolution of simple equations; and my first example shall be the equation given in the last article, in order to trace out the number there described.

Example 1.

$$\frac{2x}{3} + 4 = \frac{7x}{12} + 9.$$

In this equation it is plain, that there are two fractions, $\frac{2x}{3}$, and $\frac{7x}{12}$, which must be taken off at two several operations, thus: as 3 is the denominator of the first fraction, multiply the whole equation by 3, and you will have $2x + 12 = \frac{21x}{12} + 27$:

again, as the denominator of the remaining fraction is 12, multiply all by 12, and you will have $24x + 144 = 21x + 324$; which is an equation free from fractions.

2dly. It must in the next place be considered, that in this last equation $24x + 144 = 21x + 324$, the unknown quantity is concerned on both sides, to wit, $24x$ on one side, and $21x$ on the other; transpose therefore $21x$, and you will have $24x - 21x + 144 = 324$, that is, $3x + 144 = 324$. If it be asked why I chuse to transpose $21x$ rather than $24x$; my answer is, that had $24x$ been transposed, the unknown quantity, or its coefficient at least, after reduction, would have been negative, contrary to the rule in the second process; for resuming the equation $24x + 144 = 21x + 324$, if $24x$ be transposed, we shall have $144 = 21x - 24x + 324$, that is, $144 = -3x + 324$: but even in this case, another transposition will set all right; for if $-3x$ be transposed in this last equation, we shall then have $3x + 144 = 324$ as before: all that can be said then against this last way is, that it creates unnecessary transpositions, which an artist would always endeavour to avoid.

3dly. Having now reduced the equation to a much greater degree of simplicity than before, to wit, $3x + 144 = 324$; because the unknown quantity $3x$ has still a loose quantity, viz. 144 joined with it, transpose that quantity 144 to the

other side of the equation, and you will have $3x = 324 - 144$, that is, $3x = 180$.

N. B. By a loose quantity I mean such a one as is joined with the unknown by the sign $+$ or $-$, and not by way of multiplication, as is the coefficient 3 in the last equation.

4thly. By this time the quantity x is very near being discovered; for if $3x = 180$, it is but dividing all by 3, and we shall have $x = 60$: 60 therefore is the number described in the last article by this property, to wit, that $\frac{2}{3}$ of it with 4 over, will amount to the same as $\frac{7}{12}$ of it with 9 over: and that 60 has this property, will now be easily made to appear synthetically; for $\frac{2}{3}$ of 60 is 40, and this with 4 over is 44; moreover $\frac{7}{12}$ of 60 is 35, and this with 9 over is also 44.

N. B. A demonstration that proves the connection between any number and the property ascribed to it, is either analytical or synthetical; if this connection is shewn by tracing the number from the property, the demonstration of it is called an analytical demonstration; but if it is shewn by tracing the property from the number, the demonstration is then said to be synthetical.

Example 2.

$$\frac{2x}{3} + 12 = \frac{4x}{5} + 6$$

Here multiply by 3, and you will have $2x + 36 = \frac{12x}{5} + 18$; multiply again by 5, and you will

have $10x + 180 = 12x + 90$; transpose $10x$, and you will have $180 = 12x - 10x + 90$, that is, $180 = 2x + 90$, or rather $2x + 90 = 180$, for I generally chuse to have the unknown quantity on the first side of the equation; transpose 90, and you will have $2x = 180 - 90$, that is, $2x = 90$; divide by 2, and you will have $x = 45$.

Proof. The original equation was $\frac{2x}{3} + 12 = \frac{4x}{5} + 6$: now if $x = 45$, we have $\frac{2x}{3} = 30$, and $\frac{4x}{5} = 36$; therefore $30 + 12 = 42$: again we have $\frac{4x}{5} = 36$, and $\frac{4x}{5} + 6 = 42$: therefore $\frac{2x}{3} + 12 = \frac{4x}{5} + 6$, because the amount of both is 42.

Of EQUATIONS in general, and their Roots.

Definitions — Equations are usually denominated from the highest power of the unknown quantity that is alone concerned in them. Thus, if the unknown quantity arises to the third power, the equation is called a cubic equation; if to the fourth, a biquadratic; if to the fifth, a quadrato-cubic; if to the

the sixth, a bicubic, &c. but if an equation can (by a bare reduction of the powers of the unknown quantity) be brought down to a lower form, it then receives its denomination from that form. Thus the equation $x^6 - ax^3 + b = 0$, where x is the unknown quantity, is called a quadratic, because, by substituting y for x^3 , it may be reduced to one: thus again, the equation $x^6 - ax^4 + bxx - c = 0$ is called a cubic equation, because it may be reduced to one by substituting y for xx .

The root of an equation is such a quantity, as being substituted for the unknown quantity, will make the two sides equal one to the other; or, which is the same thing, if all the parts of an equation be thrown to one side, and so be made equal to nothing on the other, then that is said to be the root of the equation, which being substituted for the unknown quantity, will make the whole equation to vanish. Thus the roots of the equation $xx - 8x + 15 = 0$ are 3 and 5, because either of these numbers being put for x will make the whole equation to vanish; and there are no others besides in the whole scale of numbers that will have that effect.

Every equation hath as many roots, possible and impossible, as there are dimensions in the highest power of the unknown quantity. Thus every cubic equation has three roots, every biquadratic four, &c. But it often happens that some of these roots are impossible, and sometimes that they are all so, if the index of the highest power of the unknown quantity be an even number; for if it be otherwise, the equation will always have one root at least possible, as will be evident from what will be said hereafter when we come to treat of the constitution of equations. Thus the equation $x^3 = 1$ hath indeed three roots, but it hath but one real root, to wit, unity, the other two being impossible, to wit, $\frac{-1 + \sqrt{-3}}{2}$ and $\frac{-1 - \sqrt{-3}}{2}$. Let us see, however,

how these impossible numbers, being substituted for x , will make $x^3 = 1$: and first let us make $x = \frac{-1 + \sqrt{-3}}{2}$. Make $-1 = a$, and $\sqrt{-3} = b$; then you will have $x^3 = \frac{a^3 + 3a^2b + 3ab^2 + b^3}{8}$, whereof $a^3 = -1$; $3a^2b = 3 \times \sqrt{-3} = 3\sqrt{-3}$; again, as $b = \sqrt{-3}$, we shall have $b^2 = -3$, and $3ab^2 = -3x - 3 = 9$; lastly, b^3 , or $b^2b = -3\sqrt{-3}$; therefore $x^3 = \frac{-1 + 3\sqrt{-3} + 9 - 3\sqrt{-3}}{8} = \frac{-1 + 9}{8} = 1$.

Let us now put $\frac{-1 - \sqrt{-3}}{2}$ for x ; and making $-1 = a$, and $-\sqrt{-3} = b$. we shall have the first term of x^3 , wherein b is not concerned, the same as before; but the second and fourth terms, wherein b and b^3 are concerned, will have their signs changed: therefore in this case $x^3 = \frac{-1 - 3\sqrt{-3} + 9 + 3\sqrt{-3}}{8} = 1$.

Of the generation of EQUATIONS.

To form an equation that has any number of given roots. This is easily done, first by changing the signs of all the roots given, and then joining them severally to some indeterminate quantity; for if the quantities thus constituted be multiplied all together, and the product be made equal to nothing, you will have the equation desired. As for instance, let it be required to form an equation that shall have these three roots and no more, to wit, 1, 2, and 3; now, if the signs of these roots be changed, and they be severally joined with the indeterminate quantity x , they will constitute the quantities $x-1$, $x-2$, $x-3$; multiply all these together, and making their product equal to nothing, you will have the equation desired, to wit, $x^3 - 6xx + 11x - 6 = 0$, whose roots are the numbers first proposed, to wit, 1, 2, and 3.

This may easily be tried by substituting these numbers (one after another) for x in the equation: but the reason of this method will best be perceived by resolving again the equations into its first factors, thus, $x-1 \times x-2 \times x-3 = 0$; I say then, that the roots of this equation are these three and no more, to wit, 1, 2, and 3. For first, if 1 be substituted for x in the equation $x-1 \times x-2 \times x-3 = 0$, you will have $1-1 \times 1-2 \times 1-3 = 0$; which must necessarily be so, because one of the factors, to wit, $1-1$, equals 0. Make now x equal to 2 in the foregoing equation, and you will have $2-1 \times 2-2 \times 2-3 = 0$, because $2-2$ is so. Lastly, make x equal to 3, and you will have $3-1 \times 3-2 \times 3-3 = 0$, because $3-3$ is so: therefore the three roots of this equation are the numbers 1, 2, and 3, from the very definition of a root.

Let us now see whether this equation can have any other roots besides those already mentioned; and, if possible, let r be a fourth root different from any of these: then if r be substituted for x in the equation, we should have $r-1 \times r-2 \times r-3 = 0$; but now, as r is different from any of the numbers 1, 2, and 3, by the supposition, it follows that every one of the factors, $r-1$, $r-2$, $r-3$, must be something; and if so, it will be impossible for these, when multiplied together, to produce nothing; therefore the foregoing equation admits of no other roots but those already mentioned.

If I would add a fourth root to the foregoing equation, to wit, -5 , I might either put it thus, $x-1 \times x-2 \times x-3 \times x+5 = 0$, or I might multiply the cubic equation before found, to wit, $x^3 - 6xx + 11x - 6$ by $x+5$, and so make the product $x^4 - 19xx + 49x - 30 = 0$.

Whenever an equation may be wholly divided by the simple power, or by the square, or the cube of the unknown quantity without a remainder, it is an infallible argument that one or two or three of the

roots of such an equation are equal to nothing. Thus the equation $x^4 - 6x^3 + 11x^2 - 6x = 0$ may be divided by x without a remainder; whence I conclude that one of its roots is equal to nothing, as will be evident, either by substituting nothing for x in the equation, or by considering the equation as resolved into its constituent factors thus, $x \times x - 1 \times x - 2 \times x - 3 = 0$; as if I had said $x - 0 \times x - 1 \times x - 2 \times x - 3 = 0$; whence it is evident that 0 has as good a title to be a root of this equation as any of the rest.

From what has been laid down in the last article, it appears, that if any number of equations whose parts on one side are all equal to nothing on the other, be multiplied together, they will produce an equation of a superior form, whose roots will be the same with theirs. Thus, if the following equations be multiplied together, viz. $x - 1 = 0$, whose root is 1, $x - 2 = 0$, whose root is 2, and $x - 3 = 0$, whose root is 3, they will produce the equation $x - 1 \times x - 2 \times x - 3 = 0$, whose roots are 1, 2, and 3, by the last article. Again, let these equations be multiplied together, viz. $2x - 3 = 0$, whose root is $\frac{3}{2}$, $4x - 5 = 0$, whose root is $\frac{5}{4}$, and $6x - 7 = 0$, whose root is $\frac{7}{6}$, and they will produce the equation $2x - 3 \times 4x - 5 \times 6x - 7 = 0$, whose roots are $\frac{3}{2}$, $\frac{5}{4}$, and $\frac{7}{6}$: for if $2x - 3 \times 4x - 5 \times 6x - 7 = 0$, we shall have by division $x - \frac{3}{2} \times x - \frac{5}{4} \times x - \frac{7}{6} = 0$, and the roots of this equation are $\frac{3}{2}$, $\frac{5}{4}$, and $\frac{7}{6}$, by the last article. Lastly, let these two equations be multiplied together, to wit, $xx - ax + b = 0$, whose roots we will call p and q , and $xx - cx + d = 0$, whose roots we will suppose to be r and s ; I say then that the roots of the equation $xx - ax + b \times xx - cx + d = 0$, will be p, q, r, s . For first, as p is one of the roots of the equation $xx - ax + b = 0$, it follows, from the nature of a root, that if x be put equal to p , the quantity $xx - ax + b$ must vanish; but if $xx - ax + b = 0$, then $xx - ax + b \times xx - cx + d$ must be equal to nothing; therefore p is one of the roots of the equation $xx - ax + b \times xx - cx + d = 0$: and the same may be observed in all the other roots q, r, s .

Hence it is that impossible roots creep into equations of all orders and degrees whatever: for if the roots of one or more quadratic equations that enter into the composition of an equation of a superior form, be impossible, the equation so formed must necessarily have the same impossible roots. And this is the reason why, in every equation, the number of impossible roots is always even; because the roots of a quadratic equation must always be both possible, or both impossible: but if the index of the highest term of an equation be an odd number, it must have at least one root possible, because such an equation cannot be formed wholly of quadratics;

it must have a simple equation in its composition, over and above; and the root of a simple equation is always possible.

Of the coefficients of the terms of EQUATIONS.

If the roots of an equation have all their signs changed, and the equation itself be so ordered as that all its terms on one side may be equal to nothing on the other, having unity for the coefficient of its first term; I say then, that the coefficient of the second term will be the sum of all the roots thus changed, the coefficient of the third term will be the sum of all the different products that can be made out of them by multiplying them two and two together, the coefficient of the fourth term will be the sum of all the different products that can be obtained from them by multiplying them three and three together, the coefficient of the fifth term will be the sum of all the different products that can arise by multiplying them four and four together, &c. and thus may an equation be formed that shall have any number of given roots without continual multiplication. As for instance, suppose I would form an equation that shall have these four roots, 1, 2, 3, and -5: now these roots, when their signs are changed, will be -1, -2, -3, +5, whose sum is -1; therefore -1 will be the coefficient of the second term. Again, all the different products that can be made out of them by multiplying them two and two together, are -1 $\times$ -2, -1 $\times$ -3, -1 $\times$ +5, -2 $\times$ -3, -2 $\times$ +5, -3 $\times$ +5, = +2, +3, -5, +6, -10, -15, = -19; therefore the coefficient of the third term will be -19. All the different products that can arise by multiplying them three and three together, are -1 $\times$ -2 $\times$ -3, -1 $\times$ -2 $\times$ +5, -1 $\times$ -3 $\times$ +5, -2 $\times$ -3 $\times$ +5, = -6, +10, +15, +30, = 49; therefore 49 will be the coefficient of the fourth term. Lastly, there will be but one product obtainable by multiplying them all four together, that is -1 $\times$ -2 $\times$ -3 $\times$ +5 = -30; therefore -30 will be the last term of the equation, and the whole equation will now be formed, to wit, $x^4 - x^3 - 19x^2 + 49x - 30 = 0$.

Of the number of affirmative and negative roots in an EQUATION.

When the roots of an equation are all possible, and all its parts are thrown to one side so as to be made equal to nothing on the other, the number of affirmative and negative roots may be thus determined: as often as the signs change in passing from the highest term to the lowest, just so many roots of the equation will be affirmative; and as often as like signs follow one another, so many will be negative. As for instance, in the equation $x^4 - x^3 - 19x^2 + 49x - 30 = 0$, where the order of the signs is +, -, -, +, -; + in the first term being followed by - in the second, argues one affirmative root; - in the second term followed by - in the third, argues

argues one root to be negative; — in the third term followed by + in the fourth, discovers another affirmative root; and + in the fourth term followed by — in the fifth, a third: so that if all the roots of this equation be possible, there will be three affirmative roots, and one negative, which is true; for the roots of this equation are +1, +2, +3, and —5, as was shewn in the last article.

This rule is usually ascribed to our countryman Harriott, who was undoubtedly the first discoverer of most of those general properties of equations hitherto delivered, or to be delivered. But whosoever it was that first hit upon it, this is certain, that he left no demonstration of it; nor have I ever met with one in any treatise of algebra that has hitherto fallen into my hands, though most of them make mention of the rule. And, indeed, whoever considers the immense number of cases that must necessarily come under consideration in a demonstration of this nature, will not be very ready to attempt it universally; I say universally, for equations of lower degrees are less embarrassed, as I have shewn already in the case of quadratic equations, and shall farther shew when I come more distinctly to consider cubics. On the other hand, it seems much more probable, that this rule was found out by experience than from any regular investigation of it; for let all the roots of an equation be affirmative, as $+a, +b, +c$; then the equation will be $x-a \times x-b \times x-c = 0$, that is,

$$\begin{array}{r} -a \\ x^3 - b \times x \\ -c \end{array} + \begin{array}{r} +ab \\ +ac \times \\ +bc \end{array} - abc = 0,$$

where there are as many changes of signs as there are roots. Let us now suppose all the roots of an equation to be negative, as $-a, -b, -c$; then the equation will be $x+a \times x+b \times x+c=0$, that is,

$$\begin{array}{r} +a \\ x^3 + b \times x \\ +c \end{array} + \begin{array}{r} +ab \\ +ac \times \\ +bc \end{array} + abc = 0,$$

where there are no changes of signs at all: and from the formation of equations in the last article it is very visible, that these two extreme cases will be the same, how high soever the equation rises; that is, when all the roots are affirmative, there will be as many changes of signs as there are roots; and when none are affirmative, there will be no change at all. Now the question is, whether an ingenious artifice would not take the hint, which could not well escape his observation, and immediately set himself to try, whether in all other cases the number of affirmative roots be not equal to the number of variations in the signs as they follow one another.

But here the reader ought to be put in mind, that it is very often happens, especially in geometrical problems, that the roots of equations are possible, and yet the schemes to which they relate may exhibit them impossible, upon the account of some limitation or other in the problem which does not enter

the equation. An instance or two will clear up this matter.

Let ABC (plate LIII. fig. 5.) be a circle whose diameter is AC, and let AB be any chord inscribed in it; from B, the end of the chord, draw the line BD perpendicular to the diameter AC; and let it be required, having given the lines AB and AC, to compute AD, the segment of the diameter intercepted between the point A and D the foot of the perpendicular. Join BC, and call AD x : then will the similar triangles ADB and ABC give the following proportion, viz. AC is to

AB as AB is to AD or x ; whence $x = \frac{AB^2}{AC}$;

therefore x , the root of this equation, will be equally possible, whether AB be greater or less than AC; but the problem will not be possible unless the chord AB be less than the diameter AC. Here then we have an instance of a problem's producing an equation whose root continues to be possible, even when the problem ceases to be so, on account of the limitation abovementioned, to wit, that in the problem, AB must be less than AC. To explain this mystery, let AC and AB be any two given lines, and let it be required to assign a third proportional to them, which we will call x : since then AC is to AB as AB is to x , we have again

$x = \frac{AB^2}{AC}$: but this problem is as unlimited as the

equation it produces; for it is certain the two quantities AC and AB will admit of a third proportional, whether AB be greater or less than AC. The case then stands thus: here is an equation arising from a limited problem; but this equation is also intended to solve another problem that is absolutely unlimited; therefore it ought not to be expected that the equation should be liable to any restriction, whatever may be the case of the problem that produced it.

Of the transformation of EQUATIONS.

In order to fit and prepare equations for a more easy resolution, it will be proper that the analyst be well acquainted with all the various ways of transforming equations one into another, most whereof he will meet with in the following articles:

1st. When there are fractions in any equation, they must be taken away after the same manner as in simple equations, to wit, by multiplying the whole equation into all the denominators successively: and if after this, the highest power of the unknown quantity is affected with any coefficient but unity, that coefficient must also be taken off in the following manner: let the equation, when reduced to integral terms, be $ax^3 + bxx + cx - d = 0$, where the coefficient of the highest power of the unknown quantity is a ; then assuming any indeterminate quantity, as y , make $\frac{y}{a} = x$, and substituting $\frac{y}{a}$ in-

stead

stead of x in the equation, it will stand thus, $\frac{y^3}{aa} + \frac{by}{aa} + \frac{cy}{a} - d = 0$; multiply the whole equation by aa , and you will then have an equation wherein the coefficient of the highest power of the unknown quantity is unity, to wit, $y^3 + by + acy - aad = 0$; and when, by the resolution of this equation, the value of y is discovered, that of $\frac{y}{a}$ or x , the root of the primitive equation, will also be known. Since then every equation may be reduced to another, wherein the coefficient of the highest power of the unknown quantity is unity, I shall hereafter consider all equations in that form.

2dly. After the same manner may surd quantities be sometimes also thrown out of an equation. As for instance, let the equation be $x^3 + qx - \sqrt{r} = 0$. Now, to get rid of the surd quantity $\sqrt{r}$, substitute $\frac{y}{\sqrt{r}}$ instead of x in the equation, and it will stand thus, $\frac{y^3}{r\sqrt{r}} + \frac{qy}{\sqrt{r}} - \sqrt{r} = 0$; multiply the whole equation by $r\sqrt{r}$, and you will have $y^3 + qy - r = 0$; and when in this equation the value of y is known, that of $\frac{y}{\sqrt{r}}$ or x will also be known.

3dly. Thus also may the roots of any equation be multiplied or divided by any given number whatever. As for instance, let the equation be $x^3 + qx - r = 0$, and let it be required to multiply the roots of this equation by 3; that is, let it be required to find an equation whose roots shall be triple of the roots of this, each of each; and it may be thus done: because 3 is the multiplicator, make $3x = y$, and then substituting $\frac{y}{3}$ instead of x in the equation, you will have $\frac{y^3}{27} + \frac{qy}{3} - r = 0$; multiply all by 27, and you will have $y^3 + 9qy - 27r = 0$. In like manner may the roots of an equation be divided by 3 when occasion requires it, to wit, by making $\frac{x}{3} = y$, and so substituting $3y$ instead of x in the equation. *Sanderson's Algebra.*

EQUATION of Time, in astronomy, the reduction of the apparent time or motion of the sun to

equable, mean, or true time. Because we know no body in nature which preserves constantly a perfect uniform motion; and yet such a motion is only proper to measure equal days and hours; it is convenient to imagine some body or star which moves in the equator eastward, and which never quickens or slackens its pace, but goes through the equator in precisely the same time as the sun finishes his period in the ecliptic. The motion of such a star will rightly represent equal time, and its diurnal motion in the equator will be daily $59' 8''$, the same as is the mean motion of the sun in the ecliptic: and therefore the equal and middle day is to be determined by the arrival of this star to the meridian, and is equal to the time in which the whole circumference of the equator or 360 degrees pass the meridian; and besides that $59' 8''$: and because this addition of $59' 8''$ always remains the same, all these mean days will be constantly equal to each other.

Since the sun goes unequally eastward according to the equator, sometimes it will come to the meridian sooner than this imaginary star, and sometimes he will touch it later than it does, and the difference is that which is between the true and apparent time. And this difference is known by having the place of the imaginary star in the equator, and the point of the equator which comes to the meridian with the sun; for the arch intercepted between them being converted into time, shews the difference between equal and apparent time, which is called the equation of time. And it is the time that flows, while the arch of the equator intercepted between the point determining the right-ascension of the sun, and the place of the imaginary star passes the meridian.

Let ÆQ (Plate LIII. fig. 6.) be a portion of the equinoctial, EC of the ecliptic, in which imagine S to be the place of the sun, SA a circle of declination passing through the sun, and meeting with the equator in A , which will be the point which comes to the meridian with the sun. Suppose m to be the place of the imaginary star which performs its period in the equator with an equal motion: and when the sun has arrived at the meridian our imaginary star will be distant from it, by the arch $m\text{A}$; and if the point m be eastward of the point A , it will come later to the meridian than it, and the apparent time will be faster than the mean; but if the place of the star m be more westerly than A , it will sooner arrive at the meridian, and the apparent time is slower than the mean. And the arch of the equator Am converted into time is the equation, which being added to, or subtracted from the apparent time gives the true, according to the point m is to the east or west of the point A ; and then we have the true time. For to know the position of the point A in respect of m , and the quantity of the arch Am , take in the equator the arch φS or $\angle\text{S}$ equal to the φS or $\angle\text{S}$ in the ecliptic; and then the

the arch sm will be the distance between the true and mean place of the sun, which therefore is given by the sun's anomaly; but the arch AS is the difference between the hypothenusa rS of the right-angled triangle rSA , and its side or base rA , which may be found by trigonometry. Moreover, the arch Am is equal to either the sum or difference of the arches As and sm ; and therefore when they are known, the arch Am will be likewise known.

Moreover we must observe, that in the first and third quadrant of the ecliptic, the point s falls upon the east-side of the point A : and therefore the arch As being turned into time, is to be subtracted; because the point S comes later to the meridian than the point A does. But in the second and fourth quadrants the point s is more westerly than A , and arrives at the meridian before it: and therefore the arch As turned into time is to be added, for to get the time when the point S arrives at the meridian. Suppose for example As be two degrees, as it is when the sun is in the 20th degree of r ; this arch turned into time is 8 minutes: and therefore we must add 8' to the apparent time, for to have the time when the point S comes to the meridian.

Moreover in the first semicircle of anomaly, that is, while the sun in this present age goes from the seventh degree of ϖ to the seventh of φ , the mean motion of the sun is greater than its true motion; therefore then the middle place precedes the true place. And therefore in all that semicircle the point m will be to the east of the point s ; and the arch ms turned into time, is to be subtracted from the time that the point S reaches the meridian: but in

the other semicircle of anomaly, after the sun has left the perigæon, or rather the earth the perihelion, the mean motion is less than the true, and then the mean place follows the true; and consequently the point m is to the west of the point S , and comes sooner to the meridian than it does: and therefore the arch ms turned into time, is to be added to the time in which S touches the meridian. Having now the distance of time between the coming of the point m to the meridian, and the coming of the point S to the same; as also the distance of time between the arrivals of the points s and A to the meridian; we shall have the distance of time between the coming of the point m to the meridian, and of the point A 's arrival to the same; that is, we shall have the difference between the apparent and true time, which is the equation of time.

For the equating of time the astronomers compose two tables, one for the arch sm , which is to be entered into with the anomaly of the sun: and if the point m be westward of the point s , they mark it with $+$ or the sign of addition; but if it be on the other side, they place $-$ or of subtraction. The other table is for the arch sA , which is the difference between the place of the sun in the ecliptic and his right-ascension. And the equations of this table are likewise marked with the signs of addition or subtraction, as the point s is to the west or east of the point A . The sum of these two equations, if they be of the same kind, that is, both to be added or both to be subtracted; or their difference, if their affections be of different kinds, make up the absolute equation of time.

Add to the apparent Time.									

The artists likewise make a table composed of both the former; but it will only serve for a time: yet it may be used for a whole age without any sensible error; for the same degree of anomaly keeps nearly in the same degree of the ecliptic the space of an age: and therefore for the space of 50 years these two equations may be joined in one. But because of the precession of the equinoxes, the sun's apogee in process of time changes its place in the ecliptic, and goes easterly with the fixed stars: and therefore in different ages the same degrees of anomaly will fall upon different degrees of the ecliptic: and therefore one table will not serve for all ages.

In the present age wherein we live, when the sun is in the 10th degree of Scorpio, the point A is at its farthest distance from *m* to the west of it; and its distance then amounts to $4^{\circ} 2' 45''$, and therefore the greatest equation in time is $16' 11''$. From thence the days begin to increase, till the sun comes to $22\frac{1}{2}$ degree of Aquarius, where it has gone to its farthest distance from *m* eastward, it being there removed 3 degrees $42\frac{1}{2}$ minutes; whence the greatest equation of time is $14' 50''$: and from thence the relative motion of the point A begins again to be westward, till the sun comes to the 24th degree of Taurus or the Bull; and there the point A is removed from *m* 1 degree $1\frac{1}{2}$ minute to the west of the star *m*, and the greatest equation of time is $4' 6''$. Thence it returns again to *m*, and moves easterly, till the sun comes into the $3\frac{1}{2}$ degrees of the Lion, where A is distant from *m* 1 degree $28\frac{1}{2}$ minutes, and the greatest equation of time is $5' 53''$: and from thence its motion begins to be to the west, till the sun arrives at the 10th of the Scorpion; and thereabouts it changes its course and goes eastward. It is plain, that when the points A and *m* coincide, that there the mean and apparent time must likewise coincide. Hence if we have a pendulum clock accurately and nicely fitted, and the motion of the hand set to equal or true time, the hand of this clock will always point out the time different from the solar time shewed by a sun-dial; except four times a year, which is about the 4th of April, the 6th of June, the 20th of August, and the 13th of December. At all other times the hour by the sun-dial will either be before or later than that shewed by the hand of the clock: and about the 23d of October the clock will differ most of all from the sun, where its motion is slower than the solar time by $16' 11''$.

If you inquire in what points the equations are the greatest, the eminent Dr. Edmund Halley, who for his great inventions is never to be mentioned by astronomers without honour, has given us the solution of this problem. But to understand it we must first lay down the following lemma.

LEMMA.

If any plain figure be projected orthographically on a plane; which is done by letting fall from every point of it perpendiculars on the plane of projection; the area of that projection of the figure will be to the figure projected, as the co-sine of the inclination of the planes is to the radius.

For any figure can always be resolved into parallelograms or triangles, whose bases are parallel to the common section of the planes; and therefore they will be parallel to the plane on which they are projected: wherefore the bases of these parallelograms or triangles, and their projections on the plane, are always equal to each other, and parallel. But the perpendiculars let fall from the summits or tops of the triangles and parallelograms upon the bases,

bases, are also perpendicular to the common section of the planes, by the 29th to the first el. And therefore the inclination of the perpendiculars to the plane is equal to the inclination of the planes to each other. And consequently the projections of these perpendiculars will be to the perpendiculars themselves, as the co-sine of the inclination of the plane is to the radius. Wherefore every parallelogram or triangle is projected into another, whose base is equal to the base of the triangle or parallelogram projected; and its height is to the height of the figure projected as the co-sine of the inclination of the planes is to the radius. But triangles and parallelograms whose bases are equal are as the perpendiculars let fall from the tops upon the bases. The projection therefore of each triangle is to the triangle projected in a constant and given proportion; consequently all the projections of all the triangles or parallelograms are to the figures projected in the same proportion; that is, the projection is to the figure projected as the co-sine of the inclination is to the radius.

If the orbit of the earth be orthographically projected on the plane of the equator, by letting fall from each of its points perpendiculars, the projection will be an ellipse, in whose perimeter the extremity of a right line let fall from the earth, perpendicular to the plane of the equator, will constantly move: and this point by its motion will mark out the right ascension of the earth, or its motion according to the equator, as it is to be seen from the sun; to which the right ascension of the sun seen from the earth is always equal. Let $\varphi A \triangleq C$ (fig. 7.) be the ellipse in which the orbit of the earth is projected, S the point of projection of the sun's center, $\varphi S \triangleq$ the common intersection of the equator and the ecliptic, A any point, where a perpendicular from the earth meets with the projection: the angle φSA will measure the right ascension of the sun. Now I say, that this point A which marks out the motion of right ascension, will so proceed in the ellipse $\varphi A \triangleq C$, that it will describe about the point S elliptic areas proportional to the times. For in a given time let A move through the elliptic arch AB ; draw the lines AS and BS ; and the trilineal figure ASB will be the projection of the correspondent area which the earth describes in the plane of the ecliptic, in the same time, round the sun: and therefore the projection ASB will be to the correspondent area in the earth's elliptic orbit, as the co-sine of the inclination of the equator and the ecliptic is to the radius. But in the same proportion is the whole elliptic area $\varphi A \triangleq C$ to the whole area of the earth's orbit: therefore by permutation of proportion, the trilineal figure ASB will be to the whole elliptic area $\varphi A \triangleq C$, as the area described in the earth's orbit round the sun is the whole area of the earth's orbit; that is, as the time in which that area in the orbit of the earth, or the area ASB

in the projection, as described, is to the whole periodical time. Therefore the point A moves in the perimeter of the ellipse at such a rate, that it describes about S area's that are continually proportional to the times.

The same things being laid down; at the center S and distance SA , which is a mean proportional between half the greater and half the lesser axis of the ellipse, describe a circle; this circle will be equal to the whole elliptic area; as it is easy to demonstrate from the doctrine of the conick sections; this circle will cut the ellipse in four points E , F , G , H , (fig. 8.) the points of intersection shew the right ascensions of the sun, where the equations are greatest. Imagine a point M to move uniformly in the periphery of the circle; its motion will then represent the motion of our imaginary star m , and will describe about the point S circular sectors that are proportional to the time; and because the area of the whole circle and the area of the ellipse are equal, the areas of the elliptic sectors and of the circular sectors, described in the same time, will be constantly equal. Let us now suppose that the point M in the periphery of the circle, and the point that marks out the sun's right ascension in the ellipse, be placed at the same time both in the right-line SLM . Let these points afterwards be in m and A , then the elliptic area LSA will be equal to the circular sector MSm ; and because the arch Mm is without the ellipse, the angle MSm will be less than the angle MSA , and the difference of the angles measured by the arch mA , which is the equation of time. When the point which marks out the right ascension of the sun comes to the intersection F of the circle and ellipse, there its angular motion round the sun will be equal to the angular motion of the point m ; for the areas mSn and ASF are equal, they being both described in the same moment of time, and at the same distance from S ; and consequently the arch qF is equal to the arch mn . In the point therefore F , the motion of right ascension is equal to the motion of the imaginary star, or equal to the mean motion. The same thing may be shewed at G , H and E : but it was shewed before, that where the motion of right ascension was equal to the motion of the point m , that there the equations are greatest. Wherefore in the points F , G , H and E , are the equations greatest.

EQUATOR, in geography, a great circle of the terrestrial globe, equidistant from its poles, and dividing it into two equal hemispheres; one north, and the other south. See the article **GLOBE**.

It passes through the east and west points of the horizon, and at the meridian is raised as much above the horizon as is the complement of the latitude of the place. From this circle, the latitude of places, whether north or south, begin to be reckoned, in degrees of the meridian. See **LATITUDE** and **MERIDIAN**.

EQU

All people living on this circle, called by geographers and navigators the line, have their days and nights constantly equal.

It is in degrees of the equator that the longitude of places are reckoned; and as the natural day is measured by one revolution of the equator, it follows that one hour answers to $\frac{360}{24} = 15$ degrees: hence one degree of the equator will contain four minutes of time, fifteen minutes of degree will make a minute of an hour; and, consequently, four seconds answer to one minute of a degree.

EQUERRY, in the British customs, an officer of state, under the master of the horse.

There are five equeries, who ride abroad with his majesty; for which purpose they give their attendance monthly, one at a time, and are allowed a table.

As to the equeries of the crown stable, they have this distinct appellation, as being employed in mounting, managing, and breaking the saddle-horses for his majesty's use, and holding his stirrup.

EQUESTRIAN STATUE signifies the statue of a person mounted on horseback.

EQUESTRIAN ORDER, among the Romans, signified their knights, or equites; as also their troopers, or horsemen in the field; the first of which orders stood in contradistinction to the senators, as the last did to the foot, military, or infantry: each of these distinctions was introduced into the state by Romulus.

EQUIANGULAR, in geometry, an epithet given to figures whose angles are all equal: such are a square, an equilateral triangle, &c.

EQUICRURAL, in geometry, the same with isosceles. See the article **ISOSCELES**.

EQUICULUS, or **EQULEUS**. See the article **EQULEUS**.

EQUIDIFFERENT NUMBERS, in arithmetic, are of two kinds, 1. Continually equidifferent is when, in a series of three numbers, there is the same difference between the first and second, as there is between the second and third; as 3, 6, 9. And, 2. Discretely equi-different, is when in a series of four numbers or quantities, there is the same difference between the first and second, as there is between the third and fourth: such are 3, 6, 7, 10.

EQUIDISTANT, an appellation given to things placed at equal distance from some fixed point, or place, to which they are referred.

EQUILATERAL, in general, something that hath equal sides, as an equilateral angle.

EQUILATERAL HYPERBOLA, one whose transverse diameter is equal to its parameter, and so all the other diameters equal to their parameters: in such an hyperbola, the asymptotes always cut one another at right-angles in the center. Its most simple equation, with regard to the transverse axis, is $y^2 = x^2 - a^2$; and, with regard to the conjugate, $y^2 = x^2 + a^2$, when a is the semi-transverse, or semi-conjugate.

EQU

The length of the curve cannot be found by means of the quadrature of any space, of which a conic section is any part of the perimeter. See the article **HYPERBOLA**.

EQUILIBRIUM, in mechanics, is when the two ends of a lever or balance hang so exactly even and level, that neither doth ascend or descend, but keep in a position parallel to the horizon; which is occasioned by their both being charged with an equal weight.

EQUIMULTIPLES, in arithmetic and geometry, are numbers or quantities multiplied by one and the same number or quantity. Hence, equimultiples are always in the same ratio to each other, as the simple quantities before multiplication: thus, if 6 and 8 are multiplied by 4, the equimultiples 24 and 32 will be to each other as 6 to 8.

EQUINOCTIAL, in astronomy, a great circle of the celestial globe, whose poles are the poles of the world.

It is so called, because whenever the sun comes to this circle, the days and nights are equal all over the globe; being the same with that which the sun seems to describe at the time of the two equinoxes of spring and autumn. See the article **EQUINOX**.

All stars, directly under this circle, have no declination, and always rise due east, and set full west. The hour circles are drawn at right angles to it, passing through every fifteenth degree; and the parallels to it are called parallels of declination. See the articles **DECLINATION** and **CIRCLE**.

EQUINOCTIAL Colure. See **COLURE**.

EQUINOCTIAL Dial. See **DIAL**.

EQUINOCTIAL Hour. See **Hour**.

EQUINOCTIAL Line. See **LINE**.

EQUINOCTIAL Occident. See **OCCIDENT**.

EQUINOCTIAL Orient. See **ORIENT**.

EQUINOCTIAL Point, &c. See **POINT**, &c.

EQUINOX, the time when the sun enters either of the equinoctial points, where the ecliptic intersects the equinoctial. See the preceding article.

It is so called, because when the sun is in these points, the days and nights are of an equal length all the world over. As the sun is in one of them, in the spring, viz. March 20, it is called the vernal equinox; and in the other, in autumn, viz. September 23, it is called the autumnal equinox.

Precession of the EQUINOXES. See the article **PRECESSION**.

EQUIPOLLENCE, in logic, is when there is an equivalence, or agreement, either as to the nature of things, or as to the grammatical sense of any two propositions; that is, when two propositions signify one and the same thing, though they express it after different manners.

EQUISETUM, horsetail, in botany, a genus of cryptogamous plants, of the order of the selices, or ferns, the fructifications of which are disposed on an oblong spike, and are of an orbicular figure, dit-

ditches,

viding into various angles from the base. The plant itself grows in shady woods, and on the sides of ditches, in several parts of England; and consists of jointed stalks, in some species simple, in others branched, producing setæ, or small divisions, of the same structure of the larger ones. Horsetail is accounted vulnerary and astringent, and therefore prescribed in hæmorrhages, and injuries of the kidneys and bladder.

EQUITY, in a general sense, the virtue of treating all other men according to common reason and justice, or as we would be gladly treated ourselves, when we understand aright what is our due. See the article **JUSTICE**.

EQUITY of Redemption, in our law, is applied to mortgages, as where money being due on a mortgage, the mortgagee is desirous to bar the mortgagor's equity of redemption, that is, his right to redeem the mortgage. In this case the mortgagee may oblige the mortgagor, either to pay the money, or to be foreclosed of his equity of redemption. The practice is to exhibit a bill, to which answer being put in, and a decree obtained, a master of that court certifies what is due for principal, interest, and costs, which is to be paid within the time limited by the decree; and thereupon, the estate mortgaged is to be reconveyed to the mortgagor, otherwise, for default of payment, the mortgagor is decreed to be foreclosed from all equity of redemption, and absolutely to convey the mortgaged premises to the mortgagee. See **MORTGAGE**.

EQUITY also frequently signifies the court of chancery, where controversies are determined according to the exact rules of equity and conscience, by mitigating the rigour of the common law; though even by the common and statute law there is also an equity. See the article **CHANCERY**.

EQUIVALENT, an appellation given to things which agree in nature, or other circumstances, as force, nature, &c.

EQUIVOCAL TERMS, or *Words*, among logicians, are those which have a doubtful, or double meaning.

According to Mr. Locke, the doubtfulness and uncertainty of words has its cause more in the ideas themselves, than in any incapacity of the words to signify them; and might be avoided, would people always use the same term to denote the same idea, or collection of ideas: but, adds that great man, it is hard to find a discourse on any subject where this is the case; a practice which can only be imputed to folly, or great dishonesty; since a man, in making up his accounts, might, with as much fairness, use the numerical character sometimes for one, sometimes for another collection of unities.

EQUIVOCAL ACTION is, where the effect is of a different kind from the cause producing it.

EQUIVOCAL CAUSE. See **CAUSE**.

EQUIVOCAL GENERATION, the production of

animals, without the intercourse between the sexes, by the influence of the sun or stars, &c.

The equivocal generation of plants, is their production without seed, in the ordinary course of nature. See the article **GENERATION**.

This kind of generation is now quite exploded by the learned.

EQUIVOCATION, in ethics, the crime of wilfully using equivocal terms.

EQUULEUS, or **ECUULEUS**, in antiquity, a kind of rack used for extorting a confession, at first chiefly practised on slaves, but afterwards made use of against the christians.

The equuleus was made of wood, having holes at certain distances, with a screw, by which the criminal was stretched to the third, sometimes to the fourth, or fifth holes, his arms and legs being fastened on the equuleus with cords: and thus was hoisted aloft, and extended in such a manner, that all his bones were dislocated. In this state red-hot plates were applied to his body, and he was goaded in the sides with an instrument called ungula.

EQUULEI, or **EQUICULUS**, the little horse. historians are not well agreed how this constellation obtained its name or place amongst the others, nor can it be said with certainty that it was any other than the famous Paculett, so often mentioned in the renowned history of the Seven Champions, who, after performing such great actions, was by Jupiter, at the request of St. George, and the fair Sabra, translated to the heavens, and made a constellation, containing, according to the following calculation, 10 stars, whose right ascension, declination, and variation is here settled for the year 1770.

Order.	Mag.	Name.	ayer Let.	Right Ascension	Distance from Nor. Pole.	Var. in Right Ascen.	Var. in Declination
1	5			311.33.0	86.36.53	43.2	14.2
2	6			312.35.3	83.45.5	43.6	14.2

9	6			317.17.37	83.39.10	43.2	14.6
10	4		β	317.44.26	84.12.25	44.5	14.8

EQUUS, the HORSE, in zoology. See **HORSE**.

EQUUS MARINUS, in ichthyology, the same with the morse. See **MORSE**.

ERASED, in heraldry, the same with arrache. See the article **ARRACHE**.

ERECT FLOWERS, such as grow upright without hanging or reclining the head. See the article **FLOWER**.

Q q

ERECT DIAL. See the article DIAL.

ERECT VISION. See the article VISION.

ERECTOR CLITORIS, in anatomy, one of the two muscles of the clitoris that serve for its erection.

The erectors of the clitoris arise from the ossa ischii, and are inserted into the corpora cavernosa.

ERECTOR PENIS, one of the two muscles of the penis, that serve for its erection.

These arise on each side, from the ossa ischii between the tubercle of this bone and the beginning of the corpus cavernosum, and each of them is inserted into the corpus cavernosum of its own side. These muscles, when they act together, press the veins of the back of the penis against the ossa pubis, by which they prevent the reflux of blood from the penis; and consequently, when at the same time the blood flows impetuously into the parts by the arteries, and cannot get back this way, the penis becomes erected.

ERICA, heath, in botany, a genus of plants, whose flower consists of a monopetalous campanulated corolla, containing eight capillary filaments topped with bifid antheræ; the fruit is a roundish quadrilocular capsule containing a great number of very small seeds. These plants grow wild upon barren and uncultivated places in several parts of England, and are much used for brooms, as the pliability of the branches, which are also tough and fine, makes them very fit for that purpose. The distilled waters of heath flowers is by some recommended for sore eyes, as also for the cholick; and fomentations of them are said to be good in the gout and paralytic disorders.

ERIDANUS, or FLUMEN, in astronomy, a constellation of the southern hemisphere, which was originally supposed to be the Nile, though the Romans turned it into Eridanus: and it is represented on the globe to wander several different ways. It runs up north to one of the Pisces, and according to the ancient Farnese globe, should certainly go to the other, and by Andromeda's head; but the line in that part is defaced by time, or some accident or other.

Its chief course is by the Sea-monster, from which it goes to Orion's legs in one stream; as it falls from it in another very serpentine one toward the Antarctic-pole: the chief thing to be observed is, that it is very irregular and winding.

The fabulous stories of the poets concerning this river are various. Some call it Padus, and say that it was placed in heaven in remembrance of Phaeton, who set fire to the whole world by reason of his misguiding the chariot of his father Phæbus, and was slain with a thunder bolt by Jupiter, and tumbling headlong down from heaven fell into the river Eridanus or Padus, which the Italians call Po. Others call it Flumen Orionis, or the flood of Orion, and say it was placed there to betoken the

offspring from whence he came: for according to the poets, it is thus reported concerning his birth or origin.

Jupiter, Neptune, and Mercury, once being in a frolicsome humour, travelled together on the earth in the likeness of men, and being overtaken with night, were requested by one Hyreus, a farmer and grazier, to take a lodging at his house: to whose request the gods readily yielded. The good old Hyreus, who was of a hospitable and friendly disposition, killed an ox, that he might the better entertain his new guests, and make them welcome. The gods seeing the good heart of the old gentleman and his wife, ordered him to demand whatever he thought proper in recompence for his friendly cheer. Hyreus and his wife being old, requested of the gods to gratify them with a son. The gods, to fulfill their desire, called for the hide of the ox that was slain, which being brought, they put it into the earth, and all three of them made water into it together, and then covered it up, and ordered Hyreus to dig it up in nine months afterwards, which he did, and found therein a man child, whom he called Ourion ab Urina, of piss; though afterwards omitting the second letter he was named Orion. Therefore at the time he was placed in heaven, this flood was joined hard to his heels; and the ox hide, wherein the gods did piss, was placed in his hand in memorial of his offspring. The stars in this constellation are sixty-nine, whose right ascension, declination, &c. are as follow:

ERIGERON, in botany, a genus of plants producing compound radiated flowers, composed of hermaphrodite and female corollulæ; the hermaphrodite are funnel-shaped, and cut at the top into five parts, with five hairy stamina; the female florets are ligulated, linear, and subulated, and com-

pose the rays: the fruit has no pericarpium, but the cup, which is connivent, contains the seeds, which are oblong, small, and crowned with a long down. This genus includes the conyzoides and conyzella of Dillenius.

ERINUS, in botany, a genus of plants whose flower is of the ringent kind, and contains four short didynamous stamina. The fruit is an ovate bilocular capsule, covered by the cup, and contains a great number of small seeds. This genus includes the ageratum of Tournefort.

ERIOCEPHALUS, in botany, an evergreen plant with a shrubby stalk, furnished with white woolly leaves, which are digitated, and are of a strong smell when bruised; the flowers, which are compound and radiated, are produced in small clusters at the extremity of the branches, and are composed of hermaphrodite and female corollulæ; the hermaphrodite, which compose the disk, are funnel-shaped, and the female ones, being five in number, are ligulated in the radius; the hermaphrodite florets are barren, but each of the female are succeeded by a single, roundish, naked seed, resting on a plain receptacle.

ERIPHORUM, in botany, a genus of triandrious plants, whose flower is destitute of a corolla, the calyx is an imbricated spike, with oval oblong squamæ, the seed is trigetrous, sharp-pointed, and furnished with hairs longer than the spike.

ERITHALIS, in botany, a genus of plants whose flower is monopetalous, and contains five subulated filaments, topped with oblong antheræ; the fruit is a globose coronated berry, with ten cells, containing a number of small seeds.

ERMIN, *Erminium*, in zoology, a creature whose skin is the ermin, so much esteemed as a fine fur.

This creature is properly a species of weasel, and is called by Mr. Ray, and other authors, mustela candida, the white weasel, and is in all respects like the common weasel, and is all over of a pure snow-white, except the tip of the tail, which is of as beautiful a black; and it has a little yellowish grey about the eyes, and a mark, or spot, of the same colour, on the head, another on the shoulders, and a third near the tail. Its colour is, however, very different in degree and elegance, according to the season of the year. It is frequent about rivers, and in meadows, in those countries which produce it, and feeds on moles, mice, and other small animals.

ERMIN, in heraldry, is always argent and sable, that is, a white field, or fur, with black spots. These spots are not of any determinate number, but may be more or less, at the pleasure of the painter, as the skins are thought not to be naturally so spotted; but serving for lining the garments of great persons, the furriers were wont, in order to add to their beauty, to sow bits of the black tails of the creatures.

creatures that produced them, upon the white of their skin, to render them the more conspicuous, which alteration was introduced into armory.

ERMIN, or EARS OF CORN, an order of knights in France, instituted by Francis the last of that name, duke of Brittany.

ERMINE, or cross erminé, is one composed of four ermin spots.

It is to be observed, that the colours in these arms, are not to be expressed, because neither this cross, nor these arms, can be of any other colour but white and black.

ERMINES are, by some English writers, held to be the reverse of erminé, that is, white spots on a black field, and yet the French use no such word, but call this black powdered with white *contre ermin*, which is very proper, as it denotes the reverse of ermin. See the article ERMIN.

ERMINITES should signify little ermines, but it is otherwise; for it expresses a white field powdered with black, only that every such spot hath a little red hair on each.

Erminites also signify a yellow field powdered with black, which the French express much better by *or semée d'ermine de sable*.

EROSION, among physicians, denotes much the same with corrosion, only in a stranger degree. See the articles CORROSION and CORROSIVES.

ERRATA, a list of the errors or faults in the impression of a book, generally placed at the beginning thereof.

ERRATIC, in general, something that wanders, or is not regular: hence it is, the planets are called erratic stars; as those fevers, which observe no regular periods, are denominated erratic fevers.

ERRHINES, *errhina*, in pharmacy, medicines which, when snuffed up the nose, promote a discharge of mucus from that part.

The excretion of the mucus lymph is excellently promoted by errhines and sternutatories, the former of which stimulate the pituitary coats but gently, whereas the latter more forcibly stimulate them to an excretory motion. See the article STERNUTATORY.

ERROUR, ERROR, in philosophy, a mistake of our judgment, giving assent to that which is not true.

Mr. Locke reduces the causes of error to these four; first, want of proofs; secondly, want of ability to use them; and, thirdly, want of will to use them; and fourthly, wrong measures of probability.

ERUCA ROCKET, in botany, a plant with a white, woody, slender, root, and hairy stalks. The leaves are pinnated and lacinated. The flowers are cruciform and striped: and the seed are roundish.

The smell of this plant is strong and ungrateful; as is also the taste. It is said to excite the appetite,

and help digestion, to strengthen the stomach, and to promote urine.

This plant is classed by Linnæus among the brassicas or cabbages, which see.

ERVUM, bitter vetch, in botany, a genus of plants producing papilionaceous flowers. The vexillum plane, roundish and slightly reflexed. The alæ are obtuse, and shorter by half than the vexillum: and the carina is shorter than the alæ, and acuminate.

The fruit is a thick, knotty, obtuse and oblong pod, containing four roundish seeds.

The ground seeds of a species of this genus abounds with a diuretic salt, and is therefore recommended for the stone.

ERUCTATIONS, in medicine, are the effects of flatulent foods, and the crudities thence arising. See FLATULENCY.

ERUDITION, *eruditio*, denotes an extensive acquaintance with books, especially such as treat of the Belles Lettres.

ERUPTION, in medicine, a sudden and copious excretion of humours, as pus or blood: it signifies also the same with exanthema, any breaking-out, as the pustules of the plague, small-pox, measles, &c.

ERYNGIUM, ERYNGO, or sea-holly, in botany, a genus of plants whose flowers are placed on one common receptacle. The general corolla is uniform and roundish: and the floscule, which composes it, consists each of five oblong petals knotted together by a longitudinal line, including five capillary stamina.

The fruit is of an oval figure, divided into two parts, each having one oblong taper seed.

The common eryngium grows in plenty on sandy and gravelly shores in several parts of England; the roots of which are used in medicine; and are reckoned hepatic, rephretic and alexipharmic. Their whole virtue consists in the external or cortical parts,

ERYSIMUM, hedge-mustard, in botany, a genus of plants whose flower consists of a tubulous cup, containing four oblong cruciform petals, with very obtuse points, and six stamina.

The fruit is a long, linear, four cornered pod, with two cells, filled with small round seeds.

The common erysimum, which is used in medicine, grows in great plenty in many parts of England, and flowers in July or August. It is biting and pungent, not much unlike common mustard; and in like manner, it is aperient and discutient. It is prescribed chiefly in asthma, in fæctions of the lungs and chronical coughs: for it not only dissolves the viscid matter in the lungs, but also in the stomach and intestines; whence it is good in cholics proceeding therefrom. It is also said to expel poison, destroy worms, and cure ulcers in the mouth.

ERYSIPELAS,

ERYSIPELAS, otherwise called St. Anthony's fire, is that species of inflammation, which arising in the skin, and its subjacent fat, sometimes spreads itself very far, and is accompanied with redness, heat, and pain. The part affected, when pressed with the finger, becomes remarkably white; but soon after its removal, resumes its former redness.

The word is Greek, *ερυσίπτελος*, and derived from *ερυθρος*, red, and *πελος*, livid; because of the colours it induces on the affected part.

ERYTHRINA, coral tree, in botany, a genus of plants whose flower consists of a papilionaceous pentapetalous corolla; the fruit is a very long pod, protuberant by the seeds terminating in a small point, and consisting of one cell, which is filled with kidney-shaped seeds.

This genus includes the coralodendrum of Tournefort, and the coral of Dillierius; but being somewhat tender, they require a hot-house in this country, particularly to produce their flowers, which grow in spikes, and are of a beautiful scarlet colour.

These plants are best propagated by sowing their seeds in the spring on a hot-bed, and afterwards transplanted singly into pots, and plunged into the bark-bed in the stove.

ERYTHROIDES, in anatomy, the first part of the proper tunics or coats which cover the testicles. See **TESTICLE**.

ERYTHRONIUM, dog's-tooth violet, in botany, a genus of plants whose flower consists of six oblong lanceolated reflexed petals, spreading open at their base with six filaments topped with oblong erect furrowed antheræ, the fruit is a subglobose capsule, with three cells, including a number of ovate acuminate seeds.

The root is recommended against the cholic, epilepsy, and worms; it is also reckoned a provocative to venery.

This genus comprehends the *dens canis* of Tournefort.

ERYTHROXYLON, in botany, a genus of plants, whose flower consists of five ovate concave patent petals, with ten filaments topped with heart-shaped antheræ; the fruit is an egg-shaped unilocular drupe, containing an oblong quadrangular nut.

ESCALADE, or **SCALADE**, in the art of war. See the article **SCALADE**.

ESCAPE, in law, a violent or privy evasion out of some lawful restraint, without being delivered by due course of law.

ESCAPE-WARRANT, a process which issues out against a person committed in the King's-bench or Fleet-prisons, that, without being duly discharged, takes upon him to go at large.

Upon this warrant, which is obtained on oath, a person may be apprehended on a Sunday.

ESCHALOT, or **SHALLOT**, a species of the onion, much used in cookery. See **ONION**.

ESCHEAT, in law, signifies any lands or tenements that casually fall to a lord within his manor, by way of forfeiture, or by the death of his tenant, without heirs general or special.

ESCHRAKITES, in matters of religion, a sect of Mahometans, who believe that man's sovereign good consists in the contemplation of God. They avoid all manner of vice, and appear always in good humour, despising the sensual paradise of Mahomet. The most able preachers in the royal mosques are of this sect.

ESCLATTE, in heraldry, signifies a thing forcibly broken; or rather a shield that has been broken and shattered with the stroke of a battle-ax.

ESCORT, in the art of war, the same with convey. See the article **CONVOY**.

ESCULENT, an appellation given to such plants or the roots of them, as may be eaten as food; such are cabbages, onions, carrots, turnips, parsnips, potatoes, radishes, &c.

ESCULUS, or **ÆSCULUS**, the horse-chestnut, in botany. See the article **HORSE-CHESNUT**.

ESCUTCHEON, or **SCUTCHEON**, in heraldry, is derived from the French *escuillon*, and that from the Latin *scutum*, and signifies the shield whereon coats of arms are represented.

Most nations, of the remotest antiquity, were wont to have their shields distinguished by certain marks painted on them; and to have such on their shields was a token of honour, none being permitted to have them till they had performed some honourable action.

The escutcheon, as used at present, is square, only rounded off at the bottom.

As to the bearings on shields, they might at first be arbitrary, according to the fancy of the bearer, but, in process of time, they came to be the gift of kings and generals, as the reward of honourable actions.

ESCUTCHEON of Pretence, that on which a man carries his wife's coat of arms, being an heiress, and having issue by her. It is placed over the coat of the husband, who thereby shows forth his pretensions to her lands.

ESDRAS, the name of two apocryphal books, usually bound up with the scriptures. They were always excluded the Jewish canon, and are too absurd to be admitted as canonical by the papists themselves. The first book is chiefly historical, giving an account of the return of the Jews from the Babylonish captivity, and the building of the second temple; the second is written in the prophetic way, pretending to visions and revelations, but such as are extremely ridiculous.

ESLIRASS, in law, persons particularly appointed or chosen to impanel juries.

ESNECY, in law, a private prerogative allowed to the eldest coparcener, where an estate is descend-

ed to daughters for want of an heir male, to choose first, after the estate of inheritance is divided.

ESPALIERS, in gardening, are rows of trees planted in gardens, either to enclose particular quarters of a garden, or the whole; the trees are most commonly fruit bearing, as apples, pears, or plumbs, these are trailed flat either to stakes or lattice work, and answers the purposes of breaking the winds from tender plants, hiding from the eye those crops which appear unsightly, and producing handsome fruit; their distance to be planted may be ten or twelve feet, but this depends on the fort and the richness of the soil: while the trees are young, it will be sufficient to drive a few stakes into the ground, to which the branches should be trained in an horizontal direction, as they are produced; afterward the espalier should be made for good, and the trees regularly pruned, trained, and fastened to it. Hardy fruit-trees, well managed by this method, are much preferable to those trained up in any other figure, upon several accounts, as these take up but little room in a garden, so as to be hurtful to the plants which grow in the quarters; likewise, the fruit upon these are better tasted than those which grow upon dwarfs, the sun and air having freer access to every part of the tree, whereby the damps arising from the ground is sooner dissipated, which is of singular advantage to fruit trees (as hath been shewn under the article **BLIGHT**). Also trees against an espalier, by being kept low and the branches fastened, the fruit is not so liable to be blown off by the wind, therefore it must be allowed that espaliers are of considerable use as well as beauty.

ESPLANADE, in fortification, the sloping of the parapet of the covert-way towards the campaign.

ESPOUSALS, in law, signify a contract or promise made between a man and a woman, to marry each other.

ESQUIRE, *Armiger*, was anciently the person that attended a knight in time of war, and carried his shield.

ESSAY, in coinage, See the article **ASSAY**.

ESSAY, in literature, a peculiar kind of composition, the character of which is to be free, easy, and natural; not tied to strict order or method, nor worked up and finished like a formal system.

ESSAY-HATCH is the miner's term for a little trench or hole, which they dig to search for shod or ore.

ESSENCE is that which constitutes the peculiar nature of any thing, and makes it to be what it is.

In philosophy, the essence of a thing is that which is the primary conception which one has of it, and is distinguished from its act, which is called its existence. Thus the essence of a rectilinear triangle consists in its being bounded by three straight lines; of a circle, in that its radii or semi-diameters

are all equal; and the essence of a square is, that it hath four right angles and four equal right-lined sides.

ESSENCE, in chemistry, is the most pure, balsamic, and subtil parts, which have been extracted from any body by means of fire.

ESSENEES, or **ESSENIANS**, in Jewish antiquity, one of the three ancient sects among that people, who outdid the pharisees in their most rigorous observances. They allowed a future state, but denied a resurrection from the dead. Their way of life was very singular: they did not marry, but adopted the children of others, whom they bred up in the institutions of their sect: they despised riches, and had all things in common; and never changed their cloaths, till they were entirely worn out. When initiated, they were strictly bound not to communicate the mysteries of their sect to others; and if any of their members were found guilty of any enormous crimes, they were expelled.

Pliny tells us, that they dwelt on the west side of the lake of Asphaltites; that they were a solitary kind of men, living without women or money, and feeding upon the fruit of the palm-tree: he adds, that they were continually recruited by new comers, whom the surges of ill fortune had made weary of the world; in which manner the sect was kept up for several thousands of years, without any being born among them. The reason why we find no mention made of them in the New Testament, may be their reclusive and retired way of life, no less than their great simplicity and honesty, whereby they lay open to no censure or reproof.

ESSENTIA, **ESSENCE**, See the article **ESSENCE**.

ESSENTIAL, something necessarily belonging to the essence or nature of a thing; from which it cannot be conceived distinct: thus the primary qualities of bodies, as extension, figure, number, &c. are essential or inseparable from them in all their changes and alterations. See the article **QUALITY**.

ESSOIN, in law, an excuse for a person summoned to appear and answer to an action on account of sickness or other just cause of his absence.

ESSOIN-DAY is regularly the first day of every term, though the fourth day after is also allowed by way of indulgence.

ESSORANT, in heraldry, denotes a bird standing on the ground with its wings expanded, as if it had been wet, and were drying itself.

ESTABLISHMENT of Dower, in law, an assurance of dower made to the wife by the husband, or some friend of his, on marriage.

ESTATE, in law, signifies the title or interest that a person has in lands, tenements, or other effects; comprehending the whole in which a person hath any property, and will pass the same.

ESTATES, in a political sense, is used either to denote

denote the dominions of some prince, or the general classes into which the people are divided.

ESTETE, in heraldry, denotes the heads of beasts torn off by main force.

ESTHER, a canonical book of the Old Testament, containing the history of a Jewish virgin, dwelling with her uncle Mordecai at Shushan, in the reign of Ahasuerus, one of the kings of Persia.

ESTOILEE, or **CROSS-ESTOILEE**, in heraldry, a star with only four long rays in form of a cross; and accordingly, broad in the center, and terminating in sharp points.

ESTOPPEL, in law, an impediment or bar to an action, which arises from a person's own fact; or rather, where he is forbid by law to speak against his deed, which he may not do, even to plead the truth.

ESTOVERS, in law, is most generally taken for certain allowances of wood made to tenants, as house-bote, hedge-bote, and plough-bote; which three are comprehended under reasonable estovers.

ESTRANGEL, **ESTRANGELUS CHARACTER**, in the Syriac grammar, a particular species or form of Syriac letters, serving as the majuscule letters of that language, and by several supposed to be the true ancient Chaldee character.

ESTRAY, in law, any beast, not wild, that is found within a lordship, and owned by no-body: in which case, being cried according to law in the two next market towns adjacent, and not claimed in a year and a day by the owner, it becomes the property of the lord of the manor or liberty wherein it was found.

ESTREAT, in law, a true copy, note, or duplicate of an original writing or record, especially fines, amercements, penalties, &c. set down and imposed in the rolls of a court, to be levied by the bailiff, or other officer.

ESTREPEMENT, in law, any spoil made by tenants for life on any lands, &c. to the prejudice of the reversioner: it is also taken to signify the making land barren, by continual ploughing and sowing, and thereby drawing out the heart of the ground without manuring, or rather good husbandry, by which means it is impaired.

It may likewise be applied to the cutting down of trees, or lopping them farther than the law allows.

ESURINE SALTS, such as are of a corroding, fretting, and eating nature; abounding chiefly in places near the sea-side, and where great quantities of coals are burnt, as appears from the speedy rusting of iron bars in the windows of houses built in such places.

ETAPPE, a term used in the French armies, for the provisions and forage allowed an army in their route through a kingdom, whether going into winter quarters, or returning to take the field. Hence, *etapier* is the undertaker or person who con-

tracts with the country or territory for furnishing the said provisions.

ETCHING, a method of engraving on copper, in which the lines or strokes, instead of being cut with a tool, or graver, are eaten in with aquafortis.

ETERNITY, an attribute of God, expressing his infinite or endless duration. See the article **GOD**.

ETHICS, or **MORALITY**, the science of manners or duty, which it traces from man's nature and condition, and shews to terminate in his happiness; or, in other words, it is the knowledge of our duty and felicity, or the art of being virtuous and happy.

ETHIOPIE YEAR. See the article **YEAR**.

ETHMOIDAL, in anatomy, is applied to one of the common sutures of the skull, which goes round the os ethmoides, from which it derives its name, and which separates it from the bones in contact with it.

ETHMOIDES, is an epithet applied to a bone at the root of the nose, called also os ethmoides. See **CRANIUM**.

The word is Greek, *ἠμοειδής*, which is derived from *ἡμος*, a strainer, and *εἶδος*, form or likeness.

ETHNOPHRONES, in church history, heretics of the seventh century, who, professing Christianity, joined thereto all the ceremonies and follies of paganism, such as judicial astrology, divinations of all kinds, &c. and who observed all the feasts, times, and seasons of the Gentiles.

ETHOPOEIA, or **ETHOLOGY**, in rhetoric, a draught, or description, expressing the manners, passions, genius, tempers, aims, &c. of any person.

ETYMOLOGY, that part of grammar which explains the derivation of words, in order to arrive at their first and primary signification.

The word is formed of the Greek, *ετυμος*, true, and *λογια*, to say. Hence Cicero calls it *notatio* and *verilogium*. Quintilian calls it *originatio*.

EVACUANTS, in medicine, are properly such things as diminish the animal fluids by throwing out some morbid or redundant humour; or such as thin, attenuate, and promote the motion and circulation thereof.

The word is Latin, from *evacuo*, to empty or clean.

EVACUATION, in physic, the art of diminishing, emptying, or attenuating the humours of the body.

EVANGELISTS, at present, is confined to the writers of the four gospels, St. Matthew, St. Mark, St. Luke, and St. John. The apostle Paul, enumerating the several orders of Christians, according to the gifts bestowed on them, reckons evangelists in the third place, after apostles and prophets, and before pastors, and teachers.

The word is derived from the Greek *εὐαγγελος*, which is derived from *eu*, well, and *αγγελος*, an angel, or messenger.

EVANID

EVANID, a name given by some authors to such colours as are of no long duration, as those in the rainbow, in clouds before and after sunset, &c.

Evavid colours are also called fantastical and empirical colours.

EVANTES, in antiquity, the priestesses of Bacchus; thus called, by reason that in celebrating the orgia, they ran about as if distracted, crying, *evan, evan, ohé evan*.

EVAPORATION, in philosophy, is the act by which the moisture in any body is exhaled or evaporated, either by the heat of the sun, or by means of fire.

The word is Latin, *evaporatio*, and derived from *e*, out of, and *vapor*, a vapour.

EVAPORATION, in chemistry, is that operation whereby the more aqueous and volatile parts of fluids are evaporated or drove away in vapours, in order to render the remaining part of a higher consistence than before.

EVASION, among lawyers, denotes a cunning or subtle endeavouring to set aside, or escape the punishment of, the law.

EVATES, a branch or division of the druids, or ancient Celtic philosophers. Strabo divides the British and Gaulish philosophers into three sects, bards, evates, and druids; but Marcellus and Hornius reduce them all to two sects, viz. the bards and druids. See the articles **BARDS** and **DRUIDS**.

EUBAGES, an order of priests, or philosophers, among the ancient Celts, or Gauls: some will have the eubages to be the same with the druids, and saronides of Diodorus; and others, that they were the same with what Strabo calls evates.

EUCHARIST, the sacrament of the Lord's supper.

The word is Greek *ευχαριστια*, derived from *eu*, well, and *χαρις*, favour or thanks.

In the beginning of Christianity the whole church met together at the Lord's table, generally at their public assemblies, on Sundays always, besides other days, especially Saturday; on which day all the churches in the world, except Rome and Alexandria, used to celebrate their sacrament. At first they administered the eucharist every day; afterwards four times a week: but as the power of religion declined, it fell to thrice a year, as Christmas, Easter, and Whitsuntide.

EUDISTS, a congregation of missionary priests, in France, associated under the name and title of Jesus and Mary.

EUDOXIANS, in church history, a branch of Arians. See **ARIANS**.

EVE, the same with vigil. See **VIGIL**.

EVECTION of the Moon, the same with libration. See the article **LIBRATION**.

EVERARD's Sliding-Rule. See **SLIDING-RULE**.

EVERGREENS, in gardening, a term given to those plants which continue their verdure or foliage all the year; such are pines, firs, cedars, hollies, bays, phillyreas, laurels, with many others.

EVERLASTING FLOWER, in botany. See the article **XERANTHEMUM**.

EVERLASTING PEA, in botany, a species of **LATHYRUS**, which see.

EVEDROPPERS, in law, persons who stand under the eves, walls, or windows of a house by day or by night, to listen after news, and carry it to others, thereby raising strife and contention in the neighbourhood. They are punishable in the court-leet, or quarter-sessions.

EUGENIA, in botany, a genus of plants, whose flower consists of four oblong, obtuse, concave petals, with a number of stamina inserted in the cup. The fruit is a coronated quadrangular drupe, with one cell, containing a smooth roundish nut.

EVICTION, in law, signifies a recovery of lands, or tenements by law.

EVIDENCE. See **CERTITUDE**.

EVIDENCE, in law, is the testimony a person gives in court upon any fact of which he has a personal knowledge.

EVIL, *Malum*, in philosophy, &c. is either moral or natural.

Moral evil is the disagreement between the actions of a moral agent and the rule of those actions, whatever it be.

Moral good and evil coincide with right and wrong, since that cannot be good which is wrong, nor that evil which is right.

Natural **EVIL**, whatever destroys, or any way disturbs the perfection of natural beings: such as blindness, diseases, death, &c.

Kings **EVIL**, in medicine, the same with the scrophula. See the article **SCROPHULA**.

EUMENIDES, furies, in antiquity. See the article **FURIES**.

EUNOMIANS, in church history, Christian heretics in the fourth century. They were a branch of Arians, and took their name from Eunomius, bishop of Cyzicus, who was instructed by Arius in the points which were then controverted in the church, after having at first followed the profession of arms. Eunomius so well answered the designs of his master, and declaimed so vehemently against the divinity of the Word, that the people had recourse to the authority of the prince, and had him banished; but the Arians obtained his recall, and elected him bishop of Cyzicus. The manners and doctrines of the Eunomians were the same with those of the Arians.

EUNUCHS, in church history, a sect of heretics in the third century, who were mad enough to calculate, not only those of their own persuasion, but even all others that they could lay hold of: they took

took their rise from the example of Origen, who, misunderstanding the following words of our Saviour, — "And eunuchs who made themselves eunuchs for the kingdom of heaven," castrated himself.

EVOLUTE, EVOLUTA, in the higher geometry, a curve, first proposed by Mr. Huygens, and since much studied by the later mathematicians.

The evolute is a curve, supposed to be evolved or opened, and which, in opening describes other curves.

If a thread FCM (plate LIII. fig. 9.) be wrapped or wound about the curve BCF, and then unwound again, the point M will describe the curve AMM, which Mr. Huygens, the inventor, calls a curve described from evolution; and the curve BCF is the evolute, the part MC of the thread being called the radius of the evolute. 1. When the point B falls in A, the radius MC of the evolute is equal to the arch BC; but, if not, to AB + the arch BC. 2. The radius of the evolute CM is perpendicular to the curve AM. 3. Because the radius MC of the evolute continually touches it, it is evident, from the generation of the curve described from the evolution, that it may be described through innumerable points, if the tangents in the parts of the evolute are produced until they become equal to their corresponding arches. 4. The evolute of the common parabola is a parabola of the second kind, whose parameter is $\frac{2}{3}$ of the common parabola. 5. The evolute of a cycloid is another cycloid equal and similar thereto. 6. All the arches of evolute curves are rectifiable, if the radii of the evolute can be expressed geometrically.

EVOLUTION, in arithmetic and algebra, implies the extraction of the roots or powers. See EXTRACTION.

The word is Latin, *evolutio*, formed of the preposition *e*, out; and *volvo*, I roll, or wind: q. d. an unwinding, or unrolling.

EVOLUTION, in the art of war, the motion made by a body of troops, when they are obliged to change their form and disposition, in order to preserve a post, occupy another, to attack an enemy with more advantage, or to be in a condition of defending themselves the better.

Naval EVOLUTIONS, the divers movements performed by fleets or squadrons at sea, in ranging or forming into such lines or positions as may be thought most proper or expedient, either by engaging, defending, or retreating, to the greatest advantage. This term seems to have been first applied to the manœuvres of fleets by P. L'Hôpital.

The different expeditions an admiral may be ordered upon, as well as the various circumstances that occur in conducting a fleet, first gave rise to the several lines or orders of which it is formed, whose motions form what is called evolutions. See the articles LINE, DIVISION, and SQUADRON.

Those who have any knowledge of the marine will undoubtedly allow, that the art of naval evolution is absolutely necessary; since this art consists only in the manner of regulating the several movements of a naval armament. Without this art it resembles that of the most barbarous nations who have not the least knowledge of war, who act without any other rule or order than what their wild ungoverned imaginations suggest to them, or chance throws in their way. Without a proper knowledge of the art of evolutions, an admiral will dispose of his fleet very imperfectly, whether in opposing the enemy, cutting them off, doubling upon, avoiding or chasing them to the greatest advantage; for all these things require that an admiral should move each part of his fleet, as the mind moves the different members of the human body.

EVOLVULUS, in botany, a genus of plants whose corolla is monopetalous, with five capillary stamina. The fruit is a subglobose capsule, having four cells, each containing a roundish seed.

EUONYMUS, the spindle-tree, in botany, a genus of plants whose flower consists of a monophyllous cup, with four or five ovated plane and patent petals; the stamina are five subulated erect filaments topped with twin antheræ. The fruit is a succulent, four or five cornered, coloured capsule, with the same number of cells and angles, each containing one oval seed.

A species of this genus grows naturally in England, in hedges and woods; it hath a strong woody stem, dividing into many branches which are furnished with spear-shaped leaves about three inches long, of a deep green colour, and placed opposite: it flowers the latter end of May and the beginning of June, and the fruit ripens in October.

The wood of this tree is used by the musical instrument makers for tooting of organs and virginal keys; the branches are cut for making skewers, and spindles are made of the wood, from whence came the English name, Spindle-tree; but in some countries it is called dog-wood: the other species are natives of foreign countries.

EUPATORIUM, hemp-agrimony, in botany, a genus of plants whose flowers are compound, uniform, and tubulose; the corollæ are funnel-shaped and hermaphrodite, each having five short hairy filaments topped with cylindrical antheræ: on the calyx (which is oblong and imbricated) are placed the seeds, which are oblong, and crowned with a long hairy down.

The common eupatorium, which grows naturally in most parts of England, is of a purplish green colour, and full of white pith; the leaves grow thick upon the stalks and are like those of hemp, they have a very bitter taste, with a great degree of pungency, and are said to be hepatic, aperient, and vulnerary; also good against agues and obstructions of the viscera.

S f

EUPHEMISM,

EUPHEMISM, *ευφημισμός*, in rhetoric, a figure which expresses things in themselves disagreeable and shocking, in terms implying the contrary quality.

EUPHONY, *ευφωνία*, in grammar, an easiness, smoothness, and elegance in pronunciation.

Euphony is properly a figure, whereby we suppress a letter that is too harsh, and convert it into a smoother, contrary to the ordinary rules: of this there are abundance of examples in all languages.

EUPHORBIA, or **EUPHORBUM**, in botany, a genus of plants whose flower consists of four or five petals, which are thick, gibbous, turbinated, and truncate; the fruit is a roundish trilocular capsule, containing three roundish seeds.

There are many different species of the euphorbium, several of which are natives of Africa, and preserved in Europe in the hot-houses of the curious. Whether the official gummy resin of that name is extracted from one particular species, or from several promiscuously, is uncertain. It is commonly supposed to be the produce chiefly of that called by Breynius *Euphorbium cerei effigie*, &c. euphorbium resembling the cereus or torch-thistle, with thicker stalks armed with long spines. What Ray calls the true euphorbium of the ancients is the species described in the *Hortus Malabaricus*, there named *Schadidacalli*, and by Breynius *Euphorbium Indicum*, &c. that is, Indian euphorbium, resembling the opuntia or prickly pear, with a triangular jointed stalk.

The juice is extracted by wounding the stem in different parts, pieces of sheep-skin being previously tied round near the bottom, to prevent its running down upon the ground: the incisions are made with a long handled instrument, that the operator may receive no injury from the caustic liquor spurting upon the face, &c. The juice concretes into roundish, semi-transparent whitish tears, which for the most part are internally hollow: these are the euphorbium brought to us. We commonly find bits of the stalk, prickles, and seeds of the plant intermixed, and not unfrequently small stones and sand. The whitish or pale-yellowish tears are preferred, as being the freshest; the browner or darker coloured they appear, the longer they have been kept.

Euphorbium is in taste extremely acrimonious: the slightest touch burns and corrodes the tongue: a small quantity received into the nose, occasions violent sneezing: the utmost caution is requisite in pulverizing it, to guard the eyes, nose, and mouth from the pernicious effects of the fine dust that flies off.

The acrimony of euphorbium seems to reside in the more subtle parts of the resin, which are extracted wholly by spirit of wine, and almost wholly by water, the resin and gum being nearly in equal proportions.

The extreme acrimony of this drug renders it absolutely unfit for any internal use: several correctors have, indeed, been proposed for abating its virulence, but the best of them are not to be trusted to. It is employed only, and that but seldom, for external purposes; in stimulating unguents and plasters for paralytic limbs, carious bones, and beginning scirrhus tumours. Some have ventured on a minute portion of it, mixed with other powders, as an emrhine, in obstructions of the nostrils, and mucous disorders of the head; a practice by no means advisable, as we are in no want of medicines for these purposes, equally effectual, and far more safe.

EUPHRASIA, eye-bright, in botany, a genus of plants, the corolla of which consists of a single ringent petal; the tube is of the length of the cup; the upper lip is concave and emarginated; the lower one is patent, and divided into three segments: the fruit is an ovato-oblong, compressed capsule, forming two cells: the seeds are numerous, very small, and of a roundish figure.

This plant is celebrated for curing disorders of the eyes; the leaves powdered and snuffed up the nose, is said to dissolve those thick gross humours which sometime happen in the brain.

EURYTHMY, in architecture, sculpture, painting, &c. is a kind of majestic appearance, an inexpressible elegance and easiness in the composition of all the members of a body, building, or picture, that results from their fine proportion and correspondence with each other.

The word is Greek, *ευ*, easily, and *ρυθμος*, number, order.

EUSEBIANS, a name given to Arians. See the article **ARIANS**.

EUSTATHIANS, the same with the catholics of Antioch, in the fourth century, so called from their refusing to acknowledge any other bishop beside St. Eustathius, who was depozed by the Arians.

EUSTYLE, in architecture, is a sort of building in which the pillars are placed at the most convenient distance one from another, the intercolumniations being all just two diameters and a quarter of the column, except those in the middle of the face, before and behind, which are three diameters distant.

The word is Greek, *ευςτος*, and derived from *ευ*, proper, and *στυλος*, a column.

EUTYCHIANS, in church history, heretics in the fifth century, who embraced the errors of the monk Eutyches, maintaining that there was only one nature in Christ. The divine nature, according to them, had so entirely swallowed up the human, that the latter could not be distinguished; inasmuch that Jesus was merely God, and had nothing of humanity but the appearance. This heresy was condemned in a council held at Constantinople in 448, which sentence was confirmed by a general council of Chalcedon, in 451.

EXC

EWE, the English name of a female sheep. See the article **SHEEP**.

EWRY, in the British customs, an office in the king's household, which has the care of the table linen, of laying the cloth, and serving up water, in silver ewers, after dinner.

EXACERBATION, the same with **PAROXYSM**. See the article **PAROXYSM**.

EXACTION, in law, a wrong done by an officer, or a person in pretended authority, in taking a reward or fee that is not allowed by law.

EXÆRESIS, in surgery, is the removing any thing hurtful or superfluous out of the body.

The word is Greek, from *ἐξ*, out of, and *αἵματι*, to take.

EXAGGERATION, in rhetoric, is a kind of hyperbole, whereby things are augmented or amplified, by saying more than the truth, either as to good or bad.

The word is Latin, *exaggeratio*, and derived from *ex* and *agger*, a bank.

EXALTATION, in astrology, is a dignity which a planet acquires in certain signs or parts of the zodiac, which dignity is supposed to give it an extraordinary efficacy and influence. Thus the 15° of Cancer is the exaltation of Jupiter, according to Abulmazar; that of the sun is the 19° of Aries, and that of the moon is in Taurus.

EXAMINATION, in sea affairs, a sort of naval catechism, composed of various questions put by a committee of veteran sea-captains to the midshipmen, to discover whether they are sufficiently qualified in the knowledge of their profession to become a lieutenant.

EXAMINERS, in chancery, two officers of that court, who examine, upon oath, witnesses produced in causes depending there, by either the complainant or defendant, where the witnesses live in London, or near it. Sometimes parties themselves, by particular order, are examined.

EXANTHEMA, in medicine, is a pustule or eruption on the skin, as the measles, small-pox, &c. and is generally attended with a fever, and terminates in a rash.

The word is Greek, *ἐκάνθημα*, which is derived from *ἐξ*, out of, and *αἵματι*, to flower.

EXARCH, *ἐξάρχος*, in antiquity, an officer sent by the emperors of the East, into Italy, in quality of vicar, or rather præfect, to defend that part of Italy which still continued under their obedience, and particularly the city of Ravenna, against the Lombards.

EXCELLENCY, a title anciently given to kings and emperors, but now to ambassadors, and other persons, who are not qualified for that of Highness, and yet are to be elevated above the other inferior dignities.

EXCENTRIC, or **ECCENTRIC**, in geometry, are circles that have not the same center.

EXC

The word is Latin, *excentricus*, and is derived from *ex*, out of, and *centrum*, a center.

The **excentric circle** in the Ptolemaic system is also called **deferent**, because it seems to carry the planet round in its circumference. The orbit of the sun is excentric with regard to the terrestrial globe; that is, it does not revolve round the same center.

EXCENTRIC, in the new astronomy; instead of the **excentric circles** in the Ptolemaic system, the moderns have supposed oval or elliptic ones, in order to explain the apparent irregularity of the planets, and their different distances with regard to the earth.

EXCENTRIC Equation, in the old astronomy, is an angle made by a line drawn from the center of the earth, and another drawn from the center of the excentric to the body or place of any planet; it is the same with the **prosthaphæresis**, and is equal to the difference, accounted in an arch of the ecliptic, between the sun's or planet's real and apparent place.

ECCENTRIC Place of a Planet, is the true point of the orbit upon which the circle of inclination coming from the place of a planet in its orbit, falls thereon at right-angles. Mars is very eccentric with regard to the sun.

Anomaly of the ECCENTRIC. See the article **ANOMALY**.

EXCENTRICITY, or **ECCENTRICITY**, in the Ptolemaic astronomy, is that part of the lineæ apsidium lying between the center of the earth and of the excentric; or it is that circle which the sun is supposed to move in about our earth, and which has not the earth exactly for its center. And this the ancients found must be supposed, because the sun sometimes appeared large, and then it is nearest to us; and sometimes smaller, and then it is farther off.

ECCENTRICITY of the Earth, in the new astronomy, is the distance between the focus and the center of the earth's elliptic orbit.

Mr. Whiston, in his *Prælect. Astron.* page 90, shews the method of finding this from the apparent motion of the sun, compared with the two extremes of the apsidæ: for since the true velocity of the earth in her aphelion and perihelion is in a reciprocal ratio of her distances from the sun, and that the apparent and angular velocity is in a duplicate ratio of her distances reciprocally; from the apparent difference of these two velocities, the difference of the distances, or the double excentricity, will easily be known. The excentricity of the whole distance is, at a mean, about a sixtieth part, or more accurately .01786.

EXCEPTION, in law, denotes a stop or stay to an action, and is either dilatory or peremptory, in proceedings at common law; but in chancery it is what

E X C

what the plaintiff alleges against the sufficiency of an answer, &c.

EXCEPTION to Evidence, is where a demurrer is offered in any civil cause, for the insufficiency of the evidence given, and the court does not agree to it; in such case, the court, upon request, is to seal a bill of exceptions to the evidence, which may be heard on a writ of error.

EXCEPTIONS in Deeds and Writings, is the saving a particular thing out of a general one granted by deed; as a room, shop, or cellar, out of a house; a field, or timber trees, out of land, &c.

EXCERPTA, in matters of literature. See EXTRACT.

EXCESS, in arithmetic and geometry, is the difference between any two unequal numbers or quantities, or that which is left after the lesser is taken from or out of the greater. See SUBTRACTION.

EXCHANGE, in a general sense, implies a contract or agreement whereby one thing is given or exchanged for another.

EXCHANGE, in commerce, is the trade of money carried on between one place and another, by means of bills of exchange.

The things necessary to be considered in exchange are; 1. The real monies of each country or trading town. 2. Their imaginary monies. 3. The par of exchange.

1. By real money is meant a certain quantity of metal coined by the authority of a state, and current at a certain value, by virtue of that authority.

2. By imaginary money we are to understand all denominations used to express such sums as have no real species, or coin, of the value of these denominations.

1. The real monies of England.

Gold coins.		£.	s.	d.
A guinea, valued at	—	—	1	1 0
A half guinea	—	—	0	10 6
A quarter guinea	—	—	0	5 3
Silver coins.				
A crown, valued at	—	—	0	5 0
A half crown	—	—	0	2 6
A shilling	—	—	0	1 0
A sixpence	—	—	0	0 6

Copper coins.

The half-penny, and the farthing, four of which make a penny.

Imaginary monies.

The pound, equal to twenty shillings.

The mark, equal to thirteen shillings and four pence.

The angel, equal to ten shillings.

E X C

The noble, equal to six shillings and eight pence.
The penny, equal to four farthing.

2. The real monies of Holland.

Gold coins.		Florins
A ducat, or ducatoon, valued at	—	20
A sovereign	—	15
A rose noble	—	11
Silver and copper coins.		Stivers
A ducatoon, valued at	—	63
A drix gulden	—	60
A rix-dollar	—	50
A crown	—	40
A dollar	—	30
A guld florin	—	28
A schilling or shilling	—	06
A stiver	—	01

Imaginary monies.

The guilder, or florin, of twenty stivers, or 240 groots.

The pound Flemish, of twenty shillings, or six guilders.

The groot, or penny Flemish, of half a stiver, or eight pfennicks.

The pfennick, or pfenning, or denier, $\frac{1}{16}$ of a stiver.

At Amsterdam, Rotterdam, Middleburg, &c. they keep their accounts either in guilders, stivers, and pfennicks; or pounds, shillings, and pence Flemish; which are divided as ours, viz. their pound into twenty shillings, and their shillings into twelve pence.

They exchange with London upon the pound sterling, giving for it, when at par, 10 guilders, or, which is the same thing, thirty-three shillings and four pence Flemish.

The course of exchange runs between thirty and thirty-eight shillings Flemish per pound sterling.

In Hamburg and Antwerp, they keep their accounts and exchange with London, in the same manner as with Holland.

London exchanges also with Denmark, Norway, Sweden, Muscovy, Germany, Switzerland, Savoy, &c. but it is commonly done by the way of Hamburg, Amsterdam, or Antwerp.

3. The real monies of France.

Gold coins.		Livres
Double louis d'or	—	22
Louis d'or	—	11
Half louis d'or	—	05½
Silver coins.		
Ecu or crown	—	3
Half ecu	—	1½
They have also a $\frac{1}{2}$ ecu and $\frac{1}{10}$ ecu		

Brafs

EXC

Bras coin.

The only bras coin is the fol, twenty of which make a livre.

Copper coins.

The liard or farthing, four of which make a fol.

The denier, twelve of which make a fol.

The double, which was coined for a double denier, but passes now for a liard.

Imaginary monies.

The pistole, equal to ten livres.

The livre, equal to twenty fols, or $\frac{1}{2}$ of an ecu.

At Paris, Lyons, Rouen, &c. they keep their accounts in livres, fols, and deniers: and exchange upon the ecu, or crown; the par of which, in sterling money, is four shillings and sixpence.

But it is to be observed, that the kings of France often raise the species of the kingdom to rates considerably higher than those for which they were at first coined, and consequently far above their intrinsic value: so that a crown in specie will pass at four, five, or six livres. And three such livres are still named an ecu, or crown, though of a far less value than the ecu blanc, or white crown, that is, a crown in specie. Hence it happens that the exchange is very variable, and falls low in proportion to the rising of the French money above the intrinsic worth of the species.

The course runs between twenty-five and forty pence sterling per crown, or between twenty and thirty livres per pound sterling.

N. B. The French add the term *tournois* to their money, to distinguish it from the money of other nations, in the same manner as the English add the word *sterling* to theirs.

The money of Spain is of two sorts, viz. of plate and of bullion; the plate-money is of good silver, never changes its price, and is reckoned more than twenty per cent better than the money of bullion, which is a mixture of silver and bras, and as often varying in its price. In many places they buy and sell in rials of bullion, but when they state the accounts in their books, they commonly reduce them, by an allowance of so much per cent. to rials of plate.

4. The real and imaginary monies of Spain.

Gold coins.

Mervadies

A pistole, valued at four pesos, or pieces of eight, or at — — 1088

An half pistole, at two pesos, or — — 544

Silver coins.

A peso, or piece of eight, $\frac{3}{4}$ at — — 272

A rial, at — — 34

A mervadie is a small piece of bras or copper, five of which and about $\frac{1}{2}$, are, in value, equal to an English penny.

The imaginary ducat, in exchange, is valued at

EXC

375 mervadies, but in buying and selling it is only accounted 374.

In Madrid, Seville, &c. they keep their accounts in rials and mervadies, and exchange upon the piece of eight, the par of which, with London, is four shillings and sixpence; but the course of exchange runs between fifty-two pence and seventy-two pence sterling.

5. The real monies of Portugal.

Rees.

Broad ducat of gold, valued at — — 1000

Double pistole — — — 4000

Pistole — — — 2000

Half-pistole, or mil-ree — — — 1000

Stamped patacoon — — — 600

Current patacoon — — — 500

Stamped crusade — — — 500

Current crusade — — — 400

Stamped pifo — — — 480

Teston — — — 100

There are also the fractions of a teston, at 80, 60, 40, 20, and 10 rees, which are of a mixed metal, composed of silver and bras.

There are several other species in Portugal; such as the *moidore*, a gold coin, valued at twenty-seven shillings sterling; the *John*, or *Joannes*, which is also gold, worth thirty-six shillings; the half *Joannes* and quarter *Joannes*; as also the double *Joannes*, valued at three pound twelve sterling, &c.

In Lisbon, Oporto, &c. they keep their accounts in rees, and exchange in the half pistole, or mil-ree; the par of which is about six shillings and eight-pence half-penny sterling; but the course of exchange runs commonly betwixt fifty and eighty-pence sterling per mil-ree.

6. The species or coins of Italy are very numerous, and would require more room than can be spared in this place: passing, therefore, the real monies, we shall only shew the manner of exchange between London and Genoa, Leghorn, Milan, Venice, and Rome.

At Genoa, they keep their accounts in liras, soldi, and deniers; reckoning twelve deniers to a soldi, and twenty soldi to a lire; and exchange upon the *pezzo*, of five liras, whose par is about four shillings and six-pence sterling: and the course of exchange is from forty-six to seventy-six and seventy-eight pence per *pezzo*.

At Milan they keep their accounts in the same manner, but exchange upon the ducat, of five liras fifteen soldi. The course of exchange runs from fifty-five to sixty-seven pence sterling per ducat.

At Venice, merchants keep their accounts in liras, soldi, and *pichiol*; reckoning twelve *pichiol* to the soldi, and twenty soldi to the lire. But the bank reckons by ducats and grossies. The ducat consists of twenty-four grossies. They exchange upon the ducat; the par of which is four shillings and eight-pence half-penny sterling, and the course

is from fifty-two to sixty-nine pence sterling per ducat banco.

Rome exchanges with London upon the scudi, whose par is about five shillings and sixpence sterling per scudi.

7. In the plantations of America, they reckon their monies, and keep their accounts, the same way as they do in Britain. But their money is of far less value; for bills upon London from any of the Caribbee-Islands are usually charged with 25 per cent. in favour of London; that is, if St. Christopher's, Montserrat, Antigua, &c. should draw upon London 100*l*. the merchants of London charge the drawer with 125*l*. for the said 100; and for Jamaica, Virginia, Maryland, Pensilvania, New-England, &c. the difference is commonly greater.

London exchanges also with Ireland; but the course of exchange varies according to the demand of money or bills; it is commonly between four and fifteen per cent. loss to Ireland, or in favour of London.

The end and design of exchange is to avoid the risk, and save the expence, of transferring money.

The consequence is, that bills of exchange represent money so effectually, that there is no difference between the one and the other. An example will set these propositions in a clearer light.

Let us suppose Peter of London debtor to Paul of Paris for goods received, and, at the same time, that Anthony of Paris has bought of James of London goods of an equal value: if the two creditors (Paul of Paris and James of London) exchange their debtors, a transfer of money is needless. Let Peter of London pay to James of London the sum he owes to Paul of Paris, and let James for the said sum transfer to him, by an order in writing, that which he has at Paris in the hands of Anthony. Peter, the proprietor of this order, will transfer it to Paul his creditor at Paris, and Paul, on presenting it to Anthony, will receive cash for it.

If no merchant of Paris had owed money in London, Peter would have been under the necessity of sending over money to Paris to pay his debt: or, if James had sold, at Paris, only to half the value that Peter was indebted there, the half of Peter's debt would have been acquitted, the other half by sending over the specie.

It is evident, therefore, that exchange supposes reciprocal debts, that without them it could not exist, and that it consists in the exchange of the debtors.

The example proposed proves also, that the object, end, and design of exchange, is to spare the hazard and expence of transferring money. Let us suppose the debt between the two, 100*l*. and value the risk and charges on merchandize in trade at 40*l*. it is plain each must pay 140*l*. instead of 100*l*. without an exchange of debtors.

The consequence is also completely demonstrated by this example, for the bill of exchange drawn by James of London, or Anthony of Paris, was so effectually the sign of money, that Paul of Paris, to whom it was sent, has actually received 100*l*. on presenting it.

For understanding the par of exchange, it must be observed, that it has been found convenient, in the fabrication of monies, to mix a certain quantity of baser metal, called alloy, with the pure gold and silver; and the proportion of alloy is different in different kingdoms: and accordingly, the coins are said to be of a different degree of fineness; and two coins, though of a different weight, that have an equal quantity of pure gold or silver, are said to be at par. And upon a computation it has been found, that the quantity of pure silver in an English crown is as 9 to 10; and therefore the par of the French crown is, in sterling-money, four shillings and sixpence. In like manner are other coins to be compared, in order to have their par determined.

The causes of the alteration of the par of exchange, are the alteration of public credit, and the abundance or scarcity of credits of one country upon another.

A variation in the current coin is an example of the variation which the loss of public credit makes in the par of exchange: although, at the very instant this change was made in the current coin, a new real par of exchange commenced, yet, the public credit declining, on account of the uncertainty of the property and the specie not circulating, what represents the specie must of course be under its value.

The second cause of the alteration of the par of exchange, is the abundance or scarcity of credits of one country upon another; and this abundance or scarcity proceed in general from two causes.

One is the necessity that obliges the body politic of a state to transport large sums into foreign countries, as in case of a war.

The other lies in the proportion of the current mutual debts of private persons in each state.

The private persons of two nations may contract two kinds of reciprocal debts.

The inequality of reciprocal sales will form a first kind of debts.

If one of the two nations has a great deal of money at lower interest than the other, the rich private persons in the former nation will buy up all the public securities of the other, because they will receive more interest for their money: the product of this interest, which must be paid every year, forms a second species of debts: this may be looked upon as the product of a commerce, because the national funds are negotiated; and, if you observe attentively, this is not a matter of speculation only; in this case and several others, money is the merchandize, and

and thus these two debts belong properly to what is called the balance of trade, and will occasion an abundance or scarcity of the credits of one country upon another.

When two nations would settle the balance of their commerce, that is, pay their reciprocal debts, they have recourse to the exchange of debtors; but if the reciprocal debts are not equal, the exchange of debtors will only pay a part of these debts, the surplage or balance of trade must be paid in specie.

The design and intention of exchange is to save the expence and hazard of transporting money; consequently, every private person, before he determines on this method of trade, will seek credits on the country where he stands indebted.

These credits will be dear in proportion to the difficulty of acquiring them, and consequently, to have the preference, we are obliged to pay above their real value; if the credits are easy to come at, we shall pay under their value.

Let us suppose the merchants of Paris owe the manufacturers of Rouen 20,000 livres, and that the manufacturers of Rouen owe the bankers of Paris 10,000 livres; to satisfy these demands, we must make a bill of exchange for the 10,000 livres, the reciprocal debts between Paris and Rouen, and send the other 10,000 livres from Paris to Rouen.

Let us rate the charge and hazard of sending this sum at five livres per m. Every merchant in Paris will try to save this expence, and will seek to purchase a credit of 1000 livres on Rouen; but as these credits are scarce, and difficult to procure, he will gladly give 1004 livres for a draught of 1000 livres on Rouen, and save one liver per m. Thus the scarcity of bills of exchange on Rouen will lower the price of this exchange four livres per m. under par.

EXCHANGE also signifies a place in most considerable trading cities, wherein the merchants, negociants, agents, bankers, brokers, interpreters, and other persons concerned in commerce, meet on certain days, and at certain times, in order to confer and treat together of matters relating to exchanges, assurances, freightments, and other mercantile negotiations both by sea and land.

These assemblies are held with so much exactness, that the absence of a merchant, &c. makes him suspected of drawing to a failure or bankruptcy, as not being able to stand the change.

EXCHANGERS are such as return money by bills of exchange.

EXCHEQUER, in the British jurisprudence, an ancient court of record, in which all causes concerning the revenues and rights of the crown are heard and determined, and where the crown revenues are received.

It took this name from the cloth that covered the table of the court, which was party-coloured, or chequered.

Black Book of the EXCHEQUER, a book containing a description of the court of England in 1175, and its officers, with their ranks, wages, privileges, perquisites, &c. also the revenues of the crown, both in money and cattle.

EXCISE, a certain duty or impost, charged upon liquors, as beer, ale, cyder, perry, malt, &c. and several other commodities, within the kingdom of Great-Britain, and town of Berwick upon Tweed.

The excise is one of the most considerable branches of the king's revenues. It was formerly farmed out, but is now managed for the king by commissioners in both kingdoms, who receive the whole product of the excise, and pay it into the exchequer. These commissioners are nine in number in England, and four in Scotland. The former have a salary of 1000*l.* a year, the latter 500*l.* They are obliged by oath to take no fee or reward, but from the king himself; and from them there lies an appeal to five other commissioners, called commissioners of appeals.

EXCLAMATION, in rhetoric, is an elevation of the voice which expresses the vehemence of any passion, as surprize, joy, admiration, indignation, grief, fear, desire, &c. In English the interjections O! oh! alas! &c. are generally used in exclamation, in Latin oh! heu! ah! vah! &c.

The word is Latin, and derived from *exclamo*, to cry out.

EXCOMMUNICATION, an ecclesiastical penalty or censure, whereby such persons as are guilty of any notorious crime or offence are separated from the communion of the church, and deprived of all spiritual advantages.

EXCOMMUNICATO CAPIENDO, a writ issued from the chancery upon the bishop's certifying an excommunication.

EXCORIATION, in medicine and surgery, the galling or rubbing off of the cuticle, especially of the parts between the thighs and about the anus.

EXCORTICATION, the same with barking of trees. See the article BARKING.

EXCREMENT, whatever is discharged out of the body of animals, after digestion, or whatever is otherwise superfluous or noxious in them. Urine and the feces are the gross excrements that are discharged out of the bladder or belly. Physicians likewise call excrement the various humours that are secreted from the blood through the various strainers in the body, and which serve for several uses, such as the saliva, sweat, bile, the pancreatic juice, lymph, the semen, nails, the hair, the horns and hoofs of animals.

The word is Latin, *excrementum*, which is derived from *excreo*, to spit or spawl.

EXCRESCENCE, in surgery, is any superfluous matter that grows preternaturally upon the human

human or any other body ; as wens, warfs, or any sort of swelling, particularly a fleshy tumour.

The word is Latin, *excrefcencia*, which is derived from *excrefo*, to shoot or grow out.

EXCRETION, in medicine, is the act of separating excrements, or excrementitious humours, from the aliments or blood.

The word is Latin, *excretio*, which is derived from *ex*, out of, and *creo*, to choofe.

EXCRETORY, in anatomy, is a term applied to certain little ducts or veffels which make part of the ftructure of the glands, being the fmall tubes through which the humours, feparated into the glands, are difcharged out of them into fome convenient receptacle or emunctory.

EXCURSION, in aftronomy, is ufed in a fynonymous fenfe with elongation. See the article **ELONGATION**.

EXECRATION, *excretatio*, in antiquity, a kind of punifhment, confifting of direful curfes and marks of infamy.

EXECUTION, in a general fenfe, the act of accomplifhing, finifhing, or atchieving any thing that is to be done.

EXECUTION, in law, the completing or finifhing fome act, as of judgment, deed, &c. and it ufually fignifies the obtaining poffeffion of any thing recovered by judgment of law.

Military EXECUTION, the pillaging or plundering of a country by the enemy's army.

EXECUTOR, in law, a perfon appointed by another's laft will and teftament to have the execution of the fame after his deceafe, and the difpofing of the teftator's goods and effects according to the intent of the will.

The law accounts an executor one perfon with the party whose executor he is ; having all the advantages of action, and being fubject to the fame actions as the deceafed.

Hence, as an executor derives his power wholly from the will, he may releafe a debt, or do any thing as executor, before probate of the will, provided he afterwards proves it : however, to maintain actions for debts, he muft fhew the teftament proved. He may immediately take the goods, or give power to another to feize them for him.

A perfon capable of making an executor, either makes one, two, three, or more ; and he may appoint that one fhall be his executor for one year, and another for another. If he appoints executors only for a certain number of years, after they are elapfed, the ordinary may grant adminiftration of the goods ; as he may do, till the power of the executors take place. It is alfo obfervable, that where there is no executor, there is properly no will : and where there is no will there can be no executors ; but this only regards goods ; for where lands in fee are devifed, it is a good will, though no executor be named therein.

An executor may either accept or refufe the executorfhip ; but after he has accepted the office, he fhall not refufe the fame, nor take it up after refusal. If any one of the feveral executors prove the will, it will ferve for all ; fo that the reft may at any time after join with him and intermeddle with the eftate. When any action is brought, it muft be in the name of all the executors, notwithstanding fome of them may not act ; but in any action commenced againft them, he only that adminifters is to be fued. The poffeffion of one executor is held to be poffeffion of them all ; and moft acts done by or to one, are deemed done by or to all of them.

EXECUTORY, in law, is where an eftate in fee, that is made by deed or fine, is to be executed afterwards by entry, livery, or writ. Leafes for years, annuities, conditions, &c. are termed inheritances executory.

EXECUTORY DEVISE, is when the fee by devife is vefted in any perfon, and is to be vefted in another upon contingency. In all cafes of executory devifes, the eftates defcend until the contingencies happen.

EXEDRA, in church hiftory, a name fometimes given to the ambo. See **AMBO**.

EXEDRÆ, in antiquity, a general name for fuch buildings as were diftinct from the main body of the churches, and yet within the limits of the church taken in its largeft fenfe.

EXEMPLIFICATION OF LETTERS PATENT, a tranfcript or duplicate of them, made from the inrollment thereof, and fealed with the great feal.

EXEMPTION, in law, a privilege to be free from fome fervice or appearance.

EXERCISE, is fuch an agitation of the body as produces falutary effects in the animal œconomy.

Exercise, Dr. Cheyne obferves, is indifpenfably neceffary to preferve the body in due plight ; without exercife the juices will thicken, the nerves relax, the joints ftiffen ; and, on thefe diforders, chronological difeafes and a crazy old age will enfue. The body may be confidered as a fyftem of tubes and glands admirably adapted throughout, as a proper engine for the foul to work with. Exercife ferments the humours, cafts them into their proper channel, throws off redundancies, and helps nature in thofe fecret diftributions without which the body cannot fubfift in its vigour, nor the foul act with chearfulnefs. Had not exercife been abfolutely neceffary for our well-being, nature would not have given fuch an activity to the limbs of the body, and fuch a pliancy to every part, as neceffarily produce thofe compreffions, extenfions, dilatations, and all other kinds of motions neceffary for the prefervation of fuch a fyftem of tubes and glands. And, that we might not want inducements to fuch an exercife of the body, riches and honour, even food and rai-
ment,

ment, are not to be come at, without the toil of the hands, and sweat of the brow.

He farther observes, that those organs of the body which are most used, always become the strongest. Thus the legs, feet, and thighs of chairmen, the arms and hands of watermen, the backs and shoulders of porters, grow thick and strong by use. Of all the kinds of exercise there is none which conduces so much to the health, and is every way accommodated to the body, as that of riding, which is less laborious and expensive of spirits than any other. Dr. Sydenham is very lavish in its praises. Dr. Mead too recommends it in the conclusion of his *Monita & Præcepta*.

EXERCISE, in military affairs, is the ranging a body of soldiers in form of battle, and making them perform the several motions and military evolutions with different management of their arms, in order to make them expert therein.

EXERCISES are also understood of what young gentlemen learn in the academies and riding schools, such as fencing, dancing, riding the great horse, &c.

EXERGUM, among antiquarians, a little space around or without the figures of a medal, left for the inscription, cypher, device, date, &c.

EXFOLIATION, in surgery, the scaling of a bone, or its separating into laminæ or leaves.

The word is Latin, *exfoliatio*, and derived from *ex*, and *folium*, a leaf.

EX GRAVI QUERELA, in law, is a writ that lies for the person to whom any lands or tenements in fee are devised by will, and the heir of the devise enters thereon, and detains them from the devisee.

EXHALATION, in philosophy, is applied to those dry corpuscles, as also to the pinguious, oleaginous, sulphureous particles or effluvia, that are separated from hard, earthly, fat bodies, particularly the earth itself, either by the heat of the sun, the agitation of the air, or some other causes; and being emitted upwards, to a certain height in the atmosphere, there mix with the vapours, which properly are those moist fumes that are raised from water, and other liquid bodies. and help to form clouds, which return back in dew, mist, rain, snow, hail, &c.

The word is Latin, *exhalatio*, which is derived from *exhalo*, to breathe, or steam out.

The nitrous and sulphureous exhalations are the chief matter of which thunder, lightning, dew, and other meteors are generated in the air. According to Sir Isaac Newton, true and permanent air is formed from the exhalations raised from the hardest and most compact bodies.

EXHAUSTED RECEIVER, a glass, or other vessel, out of which the air hath been drawn by means of the air-pump. See the article **AIR-PUMP**.

EXHAUSTIONS, in mathematics, is a method in frequent use among the ancient mathematicians, Euclid, Archimedes, &c. that proves the equality of two magnitudes, by a deduction ad absurdum, in supposing that, if one be greater or less than the other, there would follow an absurdity: this is founded on what Euclid says in his tenth book, namely, "That those qualities whose difference is less than any assignable one, are equal;" for if they were unequal, be the difference never so small, yet it may be so multiplied, as to become greater than either of them; if not so, then it is really nothing. This he assumes in the proof of the first proposition of book ten, which is, "That if from the greater of two quantities you take more than its half, and from the remainder more than its half, and so continually, there will at length remain a quantity less than either of those proposed."

On this foundation they demonstrate, that if a regular polygon of infinite sides be inscribed in, or circumscribed about a circle, the space that is the difference between the circle and the polygon will, by degrees, be quite exhausted, and the circle be equal to the polygon.

EXHIBIT, in law, is where a deed, or other writing, being produced in a chancery suit, to be proved by witnesses, the examiner, or commissioner appointed after the examination of any such, certifies on the back of the deed, or writing, that the same was shewn to the witness, at the time of his examination, and by him sworn to.

EXHIBITION, a benefaction settled for the benefit of scholars in the universities, that are not on the foundation.

EXHIBITION was anciently an allowance for meat and drink, such as the religious appropriators made to the poor depending vicar.

EXHORTATION, in rhetoric, differs only from suasion, as being more directly addressed to the passions.

EXIGENT, in law, a writ which lies where the defendant in a personal action cannot be found, nor any effects of his within the county, by which he may be attached or distrained.

EXIGENTERS, four officers in the court of Common-Pleas; who make all exigents and proclamations in all actions where process of outlawry lies.

EXILIUM, in law, signifies a spoiling; but seems to be restrained to the injury done to tenants by altering their tenure, ejecting them, &c.

EXISTENCE, that whereby a thing has an actual essence, or is said to exist, or be.

The word is Latin, and derived from *existo*, to be, or exist.

It has been a subject of great dispute, whether eternal bodies have any existence but in the mind; that is, whether they really exist, or exist in idea

U u

only.

only. The former opinion is supported by Mr. Locke, and the latter by Dr. Berkeley.

Those who desire to see the arguments brought by those learned authors, we refer to Locke's *Essay on Human Understanding*, and Berkeley's *Principles of Human Knowledge*.

EXIT, *Exitus*, in law, properly signifies issue, or offspring; but is also applied to issues, annual rents, and profits of lands.

EXIT, in a theatrical sense, the action of a player in going off the stage, after he has played his part.

EXODIUM, in the ancient Greek drama, one of the four parts or divisions of tragedy, being so much of the piece as included the catastrophe and unravelling of the plot, and answering nearly to our fourth and fifth acts. See **EPILOGUE**.

EXODIUM, *ἐξόδιον*, in the Septuagint, signifies the end or conclusion of a feast.

EXODUS, a canonical book in the Old Testament, being the second of the Pentateuch, or five books of Moses.

It is so called from the Greek *ἐξοδος*, going out, or departure of the children of Israel from the land of Egypt; the history of which is delivered in this book, together with the many miracles wrought on that occasion.

EX OFFICIO, among lawyers, signifies the power a person has, by virtue of his office, to do certain acts without being applied to.

EXOMPHALUS, in surgery, is a hernia, or kind of rupture, that exhibits a preternatural tumor or protuberance at the navel.

The word is Greek, *ἐξομφαλος*, and derived from *ἐξ* and *ομφαλος*, the navel.

This rupture is owing to the protrusion of the intestine, or omentum, or both of them, at the navel, and rarely happens to be the subject of an operation; for though the case is common, yet most of them are gradually formed from very small beginnings, and if they do not return into the abdomen upon lying down, in all probability they adhere without any great inconvenience to the patient, until some time or other an inflammation falls upon the intestines, which soon brings on a mortification and death; unless, by great chance, the mortified part separates from the sound one, leaving its extremity to perform the office of an anus: in this emergency, however, I think it advisable to attempt the reduction, if called in at the beginning, though the universal adhesion of the sac and its contents are a great obstacle to the success: the instance in which it is most likely to answer, is when the rupture is owing to any strain, or sudden jerk, and is attended with those disorders which follow upon the strangulation of a gut.

In this case, having tried all other means in vain, the operation is absolutely necessary: which may be thus performed: make the incision somewhat above

the tumour, on the left side of the navel, through the *membrana adiposa*; and then emptying the sac of it water, or mortified omentum, dilate the ring with the same crooked knife, conducted on your finger; after this, return the intestines and omentum into the abdomen, and dress the wound without making any ligature, but of the skin only. *Sharp's Surgery*.

EXORCISM, a ceremony consisting of prayers and conjurations to drive the devil out of persons possessed, or for the removal of any danger or diseases from man or beast, and to destroy vermin and noxious animals.

The word is Greek, *ἐξορκισμός*, and derived from *ἐξ*, out of, and *ορκος*, an oath, or religious ceremony.

The use of exorcism is almost as ancient as the church: it makes a considerable part of the superstition of the Romish church, for which she hath appointed many ridiculous ceremonies in her rituals. The Romanists not only exorcise demons, but likewise houses and other places which are haunted, as it is called; and this is done in the same manner as the exorcism of persons.

The ancient heathens practised exorcisms, but they were performed by the old women only, who, gadding from house to house, used to sprinkle them with lustral water, and lay the spirits by certain forms, some very whimsical and ridiculous ceremonies. The modern heathens of the East and West Indies have also several ceremonies among them for casting out devils and hobgoblins.

EXORDIUM, in rhetoric, is the introduction, preamble, or beginning of any discourse, serving to prepare the audience for what is to follow.

The word is Latin, and derived from *ex*, out of, and *ordior*, to begin.

It is a fault into which the ancients have very often fallen, to make an exordium that has no relation to the subject in hand: in this the Greeks took more liberty than the Latins. The exordium should be laboured with great care, whence Tully calls it *difficillima pars orationis*. It should be simple, and free from too bold metaphors: the stile should not be too much raised, nor should it run into bombast. It was forbidden to make exordiums in the Areopagus at Athens, as it is an indirect and imperceptible manner of prepossessing the audience. There are two kinds of exordiums, the one just and formal, the other vehement and abrupt. In the first, the audience is prepared and conducted by due and easy steps; in the second, the orator breaks out upon his audience at once, as if seized with some sudden passion. Such is that exordium of Isaiah, "Hear, O Heavens; and give ear, O Earth!" Abrupt exordiums are the most proper on occasions of extraordinary joy, indignation, &c.

EXOSTOSIS is a preternatural excrescence of a bone,

bone, as often happens in venereal cafes: or rather a protuberance caused by a bone's being out of its natural position.

The word is Greek, *εξωσις*, and derived from *εξ*, off, or out of, and *οσεν*, a bone.

EXOTIC, is a term chiefly applied to plants which are foreign, and not of our own growth, particularly those brought from the East and West Indies: whence the use of hot-beds, green-houses, &c. in order to make them thrive.

The word is Greek, *εξωτος*, and derived from *εξω*, from without, or abroad.

Dr. Lister, in the Philosophical Transactions, gives an account of exotic diseases, as, 1. The plague, which is properly a disease of Asia, where it is epidemic. 2. The small-pox, not known in Europe, or even Asia-Minor, or Africa, till a spice trade was opened to the remotest parts of the Indies, where it rages more cruelly than among us. 3. The griping of the guts, which he takes to be peculiar to the West-Indies, and yearly received from thence; which he says is quite different from the tormina ventris of the ancients, and is scarce ever known in the midland countries, or far in the north of England.

EXPANSION is the opening and stretching out of any body; but generally it signifies such an alteration as is made by rarefaction, and the quantity of this Dr. Halley gives in the Philosophical Transactions, N^o. 197. The law of the expansion of air is this, that the spaces into which air of a given quantity is compressed, are reciprocally proportionable to the compressing weights.

The word is Latin, *expansio*, and derived from *ex*, out of, and *pando*, to stretch.

Dr. Gregory proves, in his Astronomy, that a globe of air, of but one inch in diameter, if it had so great an expansion as it will have at a semi-diameter's distance of the earth from it, would fill all the planetary regions far beyond the sphere of Saturn.

EX PARTE, a term used in the court of chancery, where a commission is taken out and executed by one side or party only, upon the other party's neglecting or refusing to join therein.

When both parties proceed together, it is called a joint commission.

EXPECTANT, in law, signifies having relation to, or depending on: thus, where land is given to a man and his wife, and to their heirs, they have a fee simple estate; but if it be given to them and the heirs of their bodies begotten, they have an estate tail, and a fee expantant, which is opposed to fee simple.

EXPECTORANTS, *Expectorantia*, in medicine, are such things as promote a discharge of whatever is offensive to the lungs and aspara arteria.

The word is Latin, *expectorans*, and derived from *ex* and *pectus*, the breast.

EXPECTORATION, in medicine, is the act of evacuating or bringing up phlegm, or other matter, from the lungs, by coughing, spitting, &c.

The word is Latin, *expectoratio*, and derived from *ex* and *pectus*, the breast.

EXPEDITATION, in the forest-law, is the cutting out the balls of dogs fore-feet, in order to preserve the king's game.

The word is Latin, *expeditatio*, and derived from *ex* and *pes*, a foot.

EXPENDITORS, the persons who disburse or expend the money collected by the tax for repairs of sewers, after the same is paid into their hands by the collectors, as ordered by the commissioners, and for which they are to render accounts when required.

EXPERIENCE, a kind of knowledge acquired by long use, without any teacher. Mr. Locke says, that men receive all the materials of knowledge from experience and observation. See the article IDEA.

Experience then consists in the ideas of things we have seen or read, which the judgment has reflected on, to form itself a rule or method.

EXPERIMENT, in philosophy, is the trial of the result or effect of the applications and motions of certain natural bodies, in order to discover something of their motions and relations, whereby to ascertain some of their phenomena, or causes.

Toricellian EXPERIMENT. See the article TORICELLIAN.

EXPERIMENTAL PHILOSOPHY, that philosophy which proceeds on experiments, which deduces the laws of nature, and the properties and powers of bodies, and their actions upon each other, from sensible experiments and observations. The business of experimental philosophy is to enquire into and investigate the reasons and causes of the various appearances or phenomena of nature, and to make the truth or probability thereof obvious and evident to the senses, by plain, undeniable, and adequate experiments, representing the several parts of the grand machinery and agency of nature.

In our enquiries into nature we are to be conducted by those rules and maxims which are found to be genuine, and consonant to a just method of physical reasoning; and these rules of philosophizing are by the greatest master in science, Sir Isaac Newton, reckoned four, which are as follow:

1. More causes of natural things are not to be admitted, than are both true, and sufficient to explain the phenomena; for nature does nothing in vain, but is simple, and delights not in superfluous causes of things.

2. And, therefore, of natural effects of the same kind, the same causes are to be assigned, as far as it can be done; as of respiration in man and beasts, of the descent of stones in Europe and America, of light

light in a culinary fire and in the sun, and of the reflection of light in the earth and in the planets.

3. The qualities of natural bodies which cannot be increased or diminished, and agree to all bodies in which experiments can be made, are to be reckoned as the qualities of all bodies whatsoever: thus, because extension, divisibility, hardness, impenetrability, mobility, the vis inertiae, and gravity, are found in all bodies which fall under our cognizance or inspection, we may justly conclude they belong to all bodies whatsoever, and are therefore to be esteemed the original and universal properties of all natural bodies.

4. In experimental philosophy, propositions collected from the phenomena by induction, are to be deemed (notwithstanding contrary hypotheses) either exactly or very nearly true, till other phenomena occur, by which they may be rendered either more accurate, or liable to exception. This ought to be done, lest arguments of induction should be destroyed by hypotheses.

These four rules of philosophizing are premised by Sir Isaac Newton to his third book of the *Principia*; and more particularly explained by him in his *Optics*, where he exhibits the method of proceeding in philosophy, the first part of which is as follows.

As in mathematics, so in natural history, the investigation of difficult things, by way of analysis, ought always to precede the method of composition. This analysis consists in making experiments and observations, and in drawing general conclusions from them by induction (i. e. reasoning from the analogy of things by natural consequence) and admitting no objections against the conclusions, but what are taken from experiments or certain truths: and although the arguing from experiments and observations, by induction, be no demonstration of general conclusions, yet it is the best way of arguing which the nature of things admits of, and may be looked on as so much the stronger, by how much the induction is more general; and if no exception occur from phenomena, the conclusion may be pronounced generally; but if at any time afterwards, any exception shall occur from experiments, it may then be pronounced with such exceptions: by this way of analysis we may proceed from compounds to ingredients, and from motions to the causes producing them; and, in general, from effects to their causes; and from particular causes to more general ones, till the argument ends in the most general: this is the method of analysis: and that of synthesis, or composition, consists in assuming causes, discovered and established as principles, and by them explaining the phenomena proceeding from them, and proving the explanations.

EXPERIMENTUM CRUCIS, a capital, leading, or decisive experiment; thus termed, either

on account of its being like a cross, or direction post, placed in the meeting of several roads, guiding men to the true knowledge of the nature of that thing they are enquiring after; or, on account of its being a kind of torture, whereby the nature of the thing is as it were extorted by force.

EXPIATION, a religious act, by which satisfaction, atonement, or amends is made for the commission of some crime, the guilt done away, and the obligation to punishment cancelled.

Great Day of EXPIATION, an annual solemnity of the Jews, upon the tenth day of the month Tisri, which answer to our September.

EXPIATION, in a figurative sense, is applied by divines to the pardons procured to mens sins, by the merits of Christ's death.

EXPIRATION, in phisic, that part of respiration whereby the air is expelled, or driven out of the lungs. See RESPIRATION.

EXPIRATION is also used for the end of any term agreed upon. It likewise signifies death.

EXPLOSION is properly applied to the going off of gunpowder, and the report made thereby; but it is frequently used to express such sudden actions of bodies as have some resemblance thereto; such as the sudden effervescence, ebullition, and expansion that arise from the mixture of some contrary liquors; as spirit of nitre and spirit of wine; oil of vitriol and oil of turpentine; oil of vitriol and sal ammoniac, &c.

The word is Latin, *explosio*, and derived from *explodo*, to drive out.

EXPONENT, in algebra, is a number placed over any power, or involved quantity, to shew to what height the root is raised, in order to contract the work. Thus, $x^4 = \text{xxxx}$. Here 4 is the exponent of the power x , and shews that it is involved to the fourth power.

The word is derived from the Latin *expono*, to shew, or expound.

EXPONENT of a *Ratio* is the quotient arising from the division of the antecedent by the consequent.

Thus the ratio of 3 to 3 is $1\frac{1}{2}$, and the ratio of 2 to 3 is $\frac{2}{3}$. If the consequent be unity, the antecedent itself is the exponent of the ratio: and, therefore, the exponent of a ratio is to unity, as the antecedent is to the consequent.

Though the quotient, resulting from the division of the antecedent by the consequent, is generally taken for the exponent of the ratio; yet, in reality, the exponent of a ratio ought to be a logarithm. And this seems to be more agreeable to Euclid's definition of duplicate and triplicate ratios, than quotients: for 1, 3, and 9, are continual proportionals; now, if $\frac{1}{3}$ be the exponent of the ratio of 1 to 3, and $\frac{2}{3}$, or $\frac{1}{3}$, the exponent of the ratio of 3 to 9, and $\frac{1}{3}$ the exponent of the ratio of 1 to 9; and since Euclid says, "If three quantities are pro-

FELONY, in law, a capital crime, next in degree to petit treason, and committed with evil intention; as murder, theft, sodomy, rape, setting fire to houses wilfully, &c.

FELT, in commerce, a kind of stuff, composed either of wool alone, or of a mixture of wool and hair, but neither spun nor wove, deriving all its consistence from being full'd, or wrought, with lees and size.

FEMALE, a term peculiar to animals, and signifies that sex which conceives and generates its young within itself.

The word is also applied, in a figurative sense, to inanimate objects, from the resemblance they bear to the female of animals: thus we say, a female screw, a female flower, &c. See **SCREW**, **FLOWER**, &c.

FEMME COVERT, in law, a married woman. See **COVERTURE**.

FEMME SOLE, an unmarried woman, whose debts, contracted before marriage, become those of her husband after that ceremony has been performed.

FEMININE, in grammar, is that gender which denotes a female.

FEMUS, the thigh, in anatomy, is that part of the body intercepted between the buttocks and the knee. See the article **THIGH**.

FEN, a general name for boggy or marshy land, commonly overflowed with water.

In draining these sort of lands, which is the only method of making them useful, trenches and drains for carrying off the water must be formed, in order to render the surface dry, and of a proper consistence for producing vegetables.

This may be attempted by various methods; but whatever mode of proceeding be adapted, the lowest part of the ground is to be found out first, and the overflowing from great rains, and from land floods, must be provided for, in the carrying off that way; for, should this be neglected, all the labour and cost employed on the other principle would be thrown away. If it is found that this can be done, there must be afterwards cut a large drain through the middle of the land, and several smaller drains communicating with this.

The great drain must be dug deep enough to drain the whole level; and this, and all the others, must be made the narrowest at the head, and wider all the way to the mouth, where it must be widest of all.

These drains must be all well cleansed from mud and weeds every spring and autumn, and the water from land-floods must be kept from coming in upon these lands, as much as possible, that there may be the less to be drained off; the lower edges of the fen-land must be for this purpose guarded with banks to turn the water into other channels. In Essex, they have many lands that lie below the high-water

mark, and are above the low-water mark, and have land-floods or fleets running through them, which make a sort of small creek. These lands they have a very easy way of draining, though they are naturally very moist, when they first inclose them from the sea; they do it with a bank, which they extend from one side of the land they design to take in, to the other, excepting a space that they leave, where the creek or land floods run into the sea. They then prepare a wooden frame, well planked, and of a considerable thickness, fitted to the head of the creek, and capable of shutting it wholly up; in this frame they make several holes, in which are placed wooden troughs, made each of four boards, and suited in size and number to the quantity of water that is to be discharged through them from the land-floods. Each of these trunks is open towards the creek, but on the sea-side it has a door or flap, which opens when the land-flood presses against it, and gives it free passage out; but, when the sea-water is risen to the height of it and presses it, it is shut by the force, and no sea-water is let in. When this head is prepared, they let it in, and, stopping up the whole creek, they continue the banks on each side till they meet it: thus all the land-floods are let out at low-water, and not a drop of sea-water can be admitted, so that the lands are kept dry and useful, which were before rendered useless, by being drowned with salt-water at every high-water mark. The fresh-water of the creek is thus kept unmixed with the sea-water, and therefore affords good drink for the cattle, which is commonly very difficult to be had in this sort of lands, the tides spoiling what fresh-waters there are, every time they come up.

FENCE, in gardening and husbandry, a hedge, wall, ditch, bank, or other inclosure, made round gardens, fields, woods, &c. The usual fences about fields are hedges of either white or black thorn, crab, holly, alder, furze, &c. those about parks are generally of oak paling, which is very durable, and some are inclosed with walls. The principal fence for gardens are walls, and particularly for kitchen-gardens, as they are not only the best security, but are of great use to ripen fruits which are of the tender kinds. See the articles **WALLS** and **EXPOSURE**. But with respect to pleasure-gardens, walls should be avoided wherever they may intercept the prospect of the distant country; but where the objects are disagreeable, they may be used: the most proper fence for a pleasure-garden adjoining to a park, is a fosse or kind of ditch, faced with an upright wall on the garden-side, about five or six feet high, with the ground regularly sloping on the park side; by this method the view is continued without interruption, as the garden and park will appear blended in one. Another kind of fence is made by banking up the earth. See the article **EARTH-BANKS**. In Devonshire, and other places where stones are plenty, they

they make their fences with two stone walls at a proper distance, filling up the space between with earth, to any height or width at pleasure: on the top not only quicksets are planted, but timber trees thrive very well on them. Beside the above-mentioned, there are other kinds of fences, such as posts and rails, rope and net fences, reed fences, chevaux de frize to hinder the approach of cattle, &c.

FENCE-MONTH, the month wherein deer begin to fawn, during which it is unlawful to hunt in the forest.

It commences fifteen days before Midsummer, and ends fifteen days after it. This month, by ancient foresters, is called defence-month. There are also fence-months, or seasons, for fish as well as wild beasts, as appears by Stat. West. 13 Geo. II.

FENCING, the art of making a proper use of the sword, as well for attacking an enemy, as for defending one's self.

FENDERS, among sailors, certain pieces of rope, wood, faggots, or other materials, hung over the side of a ship or boat, to prevent them from striking or rubbing against each other, when they lie close together; also to prevent ships, boats, and other vessels from bearing against a wharf or key.

FENDUE en Pal, in heraldry, a cross clove down in pale, that is, from top to bottom, and the two parts set at some distance from each other.

FENESTRA, in anatomy, a term applied to two openings or foramina within the ear, distinguished by the names of the oval and the round fenestra.

FENNEL, *feniculum*, in botany, an umbelliferous plant, whose root is white, strait, of a sweetish aromatic taste, and perennial; the stalk is annual, strait, round, jointed, smooth, slender, and covered with a greenish rind; it is full of a spongy white pith, and divided into many wings towards the top; the leaves are of a dark green, and divided into long capillary segments, with a sweet pungent taste and smell, the flowers grow in umbels at the ends of the branches, in July, and are rosaceous, consisting of five yellow incurved petals; the seeds are oblong, thick, and channeled, gibbous on one side and plane on the other. The leaves, roots, and seeds, are used in medicine; the root being one of the five opening roots, and the seed one of the greater carminative seeds.

Sweet Fennel differs but little from the former, only the stalk is not so high nor so thick, and the leaves are less, but the seeds are longer, narrower, streaked and whitish, of a more sweet and aromatic taste, with nothing of the pungency of the other sort; sweet fennel seed is accounted sudorific and attenuant, considerably diuretic and fudorific, and is recommended as a specific in the measles, small-pox, and malignant fevers. The roots of fennel have exactly the same smell and taste of the

celebrated gingfeng of the Chinese; and, according to Boerhaave's opinion, it may be a very good substitute.—In the Linnæan system of botany, fennel is classed with the anethum, which see.

FENUGREEK, in botany. See the article **FOENUGREEK**.

FEOFFMENT, in law, is a gift or grant of any manors, messuages, lands, or tenements, to another in fee, that is, to him and his heirs for ever, by delivery of seisin, and possession of the estate granted.

FERALIA, in antiquity, a festival observed among the Romans, on the twenty-first of February; or, according to Ovid, on the seventeenth of that month, in honour of the manes of their deceased friends and relations.

FER DE FOURCHETTE, in heraldry, a cross, having at each end a forked iron, like that formerly used by soldiers to rest their muskets on. It differs from the cross fourché, the ends of which turn forked, whereas this has that sort of fork fixed upon the square end.

FER DE MOULIN, *Mirinde*, *Inke de Moulin*, in heraldry, is a bearing supposed to represent the iron-ink or ink of a mill, which sustains the moving mill-stone.

FERIÆ, in Roman antiquity, holidays, or days upon which they abstained from work.

FERIAL DAYS, according to the Statute 27 Hen. VI. cap. v. are taken for all days of the week except Sunday.

FERMENT, any body which, being applied to another, produces fermentation.

Ferments are either matters already in the act of fermentation, or that soon run into this act. Of the first kind are the flowers of wine, yeast, fermenting beer, or fermenting wine, &c. and of the second are the new expressed vegetable juices of summer fruits.

Among distillers, ferments are all those bodies which, when added to the liquor, only correct some fault therein, and by removing some obstacle to fermentation, forward it by secondary means; as also such as being added in time of fermentation, make the liquor yield a larger proportion of spirit, and give it a finer flavour. See the article **ADDITION**.

FERMENTATION, the intestine motion excited in vegetables, by which they are changed in such a manner, that the first thing that rises from them in distillation is acrid, mixible with water, of a warm aromatic taste, inflammable like oil, thin and volatile; or else acid, that will extinguish fire and flame, and is less thin and volatile.

The word is Latin, *fermentatio*, and derived from *fermentum*, leaven.

A certain degree of warmth seems requisite, in the northern climates, to all artificial liquors intended for immediate fermentation, especially in the winter:

winter: but the natural juices of vegetables that have never been inspissated, as that of grapes, and other fruits, when fully ripened, will usually ferment as soon as they are expressed, without any external assistance. But as a certain degree of inspissation prevents all tendency to fermentation in vegetable juices, otherwise strongly disposed to ferment; so a long continuance or increase of the inspissating heat, especially if it acts immediately, through a metalline or solid body, upon the juice, will destroy its fermenting property; and this the more effectually, as the heat employed approaches to that of scorching, or the degree capable of giving an empyreuma. After the same manner, several experiments make it appear, that there is a certain degree of heat, the continuance, or least increase whereof, proves detrimental, or destructive to fermentation, as there is another that wonderfully encourages and promotes it. These two degrees of heat ought to be carefully noted and settled by the thermometer, or other more certain method, for philosophical and chemical uses; but for common or economical occasions, they may be limited to what we usually understand by a tepid and a fervid heat: a fervid heat is the bane of all vinous fermentation; as a tepid one, or rather an imperceptible warmth, is the great promoter thereof. In this neutral state therefore, with proper contrivances to preserve and continue it, the liquor is to be put into a suitable vessel for fermentation; at which time, if it work not of itself, it must be quickened by additions; and, in general, by such things as are properly called ferments. See FERMENT.

When thus the proper quantity of a good-conditioned and suitable ferment is got ready, it must be put to the fermentable liquor in the bare tepid, or scarce luke-warm state above-mentioned. The best manner of bringing them together, for raising the fermentation quick and strong, seems to be this: when the ferment is solid, it should be broke into small pieces, and gently thinned, with the hand, or otherwise, in a little of the luke-warm liquor; but a complete uniform solution should not be here endeavoured, because this would, in some measure, weaken the power of the ferment, or destroy its future efficacy. The whole intended quantity therefore, being thus loosely mixed with a moderate quantity of the liquor, should be kept in a tepid state, free from the action of the external air; and at proper intervals more of the warm liquor should be added, till the whole quantity is well set to work together: and thus, by dividing the business into parts, it may be much more speedily and effectually performed.

FERMENTED, in general, something that has undergone a fermentation. See the preceding article.

FERN, *filix*, in botany. There are several kinds of fern in different parts of the world: but we

shall only mention two sorts. The male fern (which Linnæus has classed with the polypodium: and the female fern or brakes, which he calls *pteris*.

The leaf of the male fern is composed of several other leaves, which adhere to a rib in such a manner as to have lobes on both sides, cut into the depth of the main fibre.

The common female fern, or brakes, has many large leaves divided into several branches, beset with long, narrow, stiff pinnulæ, which are mostly smooth about the edges, though sometimes they are a little indented: the back of these, about Midsummer, will be covered round the margins with a great number of dusky brown particles, which are the seeds.

The seeds of the several species of fern were wholly unknown to the ancients. Swammerdam, in his *Biblia Naturæ*, claims to himself the honour of having first discovered them; but it appears from Hook's works, that Dr. William Cole sent an account of the seeds of several of the plants of this kind to that author, in 1669; whereas Swammerdam declares his discovery of them to have been in 1673; so that it is plain that Dr. Cole's was prior to his by some years. Swammerdam is an author of that strict probity, that there is no room to doubt but that he spoke what he thought to be true; and it is even possible that he might have discovered them sooner than the time he mentions; but, however that be, it appears from the later observations of the ingenious Dr. Miles, that his accounts are extremely accurate and just. The seed-vessels of the common fern, the English and foreign maiden-hairs, the wall-rue, hart's-tongue, and the like plants, are all alike in their general form, their only differences being in the size, and their arrangement on the plants. The number or quantity of the seeds is very different in different plants; but Dr. Miles observes, that, the fewer seeds there are in any species, there is always the more in quantity of a sort of spongy or fungous matter, which forms a kind of tubercle, not unaptly resembling what is called Jew's-ears, which seems a substance intended for the sheltering the seeds.

These seed-vessels consist of a stalk, by which they are inserted into the leaf; this represents an elastic cord, and is surrounded by a great number of annular ribs, resembling the cartilages of the aspera arteria; and indeed nothing in nature so exactly resembles this cord or stalk, as the wind-pipe of a small bird. This cord incircles the globular membranous pod, wherein the seeds lie, adhering to it, and dividing it into two hemispheres.

The pod is composed of a fine whitish membrane, somewhat like that which lines the inside of a pea-shell; the seeds are irregular in shape, and of a reticulated surface. The most advantageous way of viewing this is to use the common microscope, for

FER

opaque objects, putting on a small magnifier, and laying the seeds with their capsules, &c. as taken from the back of the plant, on a piece of polished ivory. The proper time of the year is in the beginning of September; and then, if the plant be newly gathered, the seed-vessels often burst, while they are under inspection, and shew a very elegant appearance. The manner of this bursting of the pod, which is the method nature has taken for the scattering and dispersing of the seed, is this: the cord becomes extended in some one part, and soon after breaks asunder; this by expanding bursts the pod into two parts, and, continuing to expand itself, as it departs from a curve, and approaches to a right-line, it rends itself away from the globular pod, till it be at length wholly disengaged from it; and then, as there can be no farther resistance given to its expanding, it suddenly flies off, with a sort of jerk, and becomes quite straight at once. By this last action the capsules are shook, and the seeds are discharged out of them on the plate of ivory, in the same manner as the grains of wheat or barley would be thrown out of a bowl placed on a table by the shaking of the bowl.

FERN Oil, in pottery, a name given, by the English merchants who have been in China, to a sort of varnish, which the Chinese use in their porcelain manufactories. See **CHINA**.

FERRET, *Viverra*, in zoology, a quadruped of the mustela kind.

The head is small and depressed; the snout sharp; the eyes look very fierce and red; the ears are short, patulous, and erect, they are considerably wide, especially towards the base; the mouth is large, and the teeth are very sharp; the neck is short; the body is long and thin; the legs are short, and each divided at the foot into five toes, and they are armed with sharp claws. This animal is very common in England, but is a native of America.

FERRETS, in glass-making, the iron with which the workman tries the melted metal to see if it be fit to work.

It is also used for those irons which make the ring at the neck of bottles. *Neri's Art of Glass*.

FERRETTO, in the glass trade, a substance which serves to colour glass. This is made by a simple calcination of copper, but it serves for several colours. There are two ways of making this; the first is this: take thin plates of copper, and lay them on a layer of powdered brimstone, in the bottom of a crucible; over these lay more brimstone, and over that another layer of the plates, and so on alternately, till the pot is full. Cover the pot, lute it well, place it in a wind furnace, and make a strong fire about it for two hours. When it is taken out and cooled, the copper will be found so calcined, that it may be crumbled to pieces between the fingers, like a friable earth; it will be of a reddish, and in some parts a blackish colour. This must be powdered and sifted fine for use.

FES

The other way is less easy, but it makes a more valuable ferretto. It is this: make a number of stratifications of plates of copper and powdered vitriol alternately in a crucible, which place in the floor of the glass furnace, near the eye, and let it stand there three days; then take it out, and make a new stratification with more fresh vitriol, and calcine it again as before; repeat this operation six times, and a most valuable ferretto is produced. *Neri's Art of Glass*.

FERRUGINOUS, any thing partaking of iron, or that contains particles of that metal. It is particularly applied to certain mineral springs, whose waters are impregnated with particles of iron, generally called chalybeates.

The word is Latin, *ferrugineus*, and derived from *ferrum*, iron.

FERRUGO, **RUST**. See the article **RUST**.

FERRUM, **IRON**. See **IRON**.

FERTILITY, that quality which denotes a thing fruitful or prolific.

FERULA, fennel-giant, in botany, a genus of umbelliferous plants, the compound flower of which is uniform, and the particular ones made up of five oblong erect petals with the same number of stamina; the fruit is of an elliptical compressed form, dividing in two parts, each having a plane seed of the same figure.

FERULÆ, in surgery, splinters or chips of different matter, as of wood, bark, leather, paper, &c. applied to bones that have been disjoined, when they are set again.

FESSE, in heraldry, one of the nine honourable ordinaries, consisting of a line drawn directly across the shield, from side to side, and containing the third part of it, between the honour-point and the nombril.

It represents a broad girdle or belt of honour, which knights at arms were anciently girded with.

FESSE POINT is the exact center of the escutcheon. See the article **POINT**.

FESSE WAYS, or *In Fesse*, denotes any thing borne after the manner of a fesse; that is, in a rank across the middle of the shield.

Party per Fesse implies a parting across the middle of the shield, from side to side, through the fesse-point.

FESTI DIES, in Roman antiquity, certain days in the year devoted to the honour of the gods.

FESTINO, in logic, the third mood of the second figure of syllogism, the first proposition of which is an universal negative, the second a particular affirmative, and the third a particular negative, as in the following example:

FES No bad man can be happy,

TI Some rich men are bad men:

NO *Ergo*, Some rich men are not happy.

FESTIVAL, the same with feast. See the article **FEAST**.

FESTOON, in architecture and sculpture, &c. an ornament in form of a garland of flowers, fruits, and leaves, intermixed or twisted together.

It is in the form of a string or collar, somewhat biggest in the middle, where it falls down in an arch; being extended by two ends, the extremities of which hang down perpendicularly.

Festoons are now chiefly used in friezes, and other vacant places, which want to be filled up and adorned; being done in imitation of the long clusters of flowers, which the ancients placed on the doors of their temples and houses on festival occasions.

FESTUCA, in botany, a genus of grasses, the flower of which is composed of two valves, and terminated by a strait arista or awn; the seed is single, oblong, very sharp pointed at each end, and marked with a longitudinal furrow.

FETLOCK, in the menage, a tuft of hair growing behind the pattern-joint of many horses; for those of a low size have scarce any such tuft.

FEUD, *Feodum*, the same with *fec*. See the article **FEE-ESTATE**.

FEUDAL, or **FEODAL**, denotes any thing belonging to a fee. See the article **FEE**.

FEUDATARY, or **FEODATARY**, a tenant who formerly held his estate by feudal service. See the article **VASSAL**.

FEVER, **FEBRIS**, in medicine, a disease, or rather class of diseases, whose characteristic is a preternatural heat felt through the whole body, or at least the principal parts of it.

All fevers, of what kind soever, are attended with a preternatural heat of the blood and humours, which impairs the bodily strength and its vital functions: wherefore nature raises all her forces, and engages the disease as a mortal enemy; and, if she gets the better, drives out the cause of the disorder by such outlets as she is able. This action is by physicians called the crisis of the disease.

As there is no fever cured without some considerable evacuation, raised either by nature or by art, the physician ought carefully to observe which way nature seems to intend the expulsion of the morbid matter, and to assist her by all possible means. Now this expulsion is very frequently made through several outlets of the body at a time; and an evacuation by one outlet, more or less, checks that by another; thus a looseness checks a sweat, and *vice versa*: wherefore it is the physicians business to discern what evacuation is most likely to be of service, and so to promote this, as to give the least interruption possible to any other; for any one evacuation is not equally suitable to all persons, both on account of the difference of constitution and of diseases; although evacuations through every emunctory are sometimes necessary, as we find by experience in malignant fevers.

But of all solutions of the disease the most desirable is by sweat; next to that by stool and urine;

the worst is by a hæmorrhage, whether it proceeds from the nose, or from any other part, because it indicates, that the blood is so far vitiated, that no proper separation of the humour can be made.

Lastly, some fevers terminate in abscesses formed in the glands, which, if they happen in the decline of the disease, and suppurate kindly, are salutary: wherefore the suppuration is to be forwarded by cataplasms or plasters, and sometimes by cupping on the tumour; and then, if the abscess does not break spontaneously, it ought to be opened with the knife or a caustic.

At this time this rule of practice is generally right, not to exhaust the patient's strength by evacuations of any kind: and yet in some cases there is a necessity for drawing a little blood; as when the humours are in great commotion, and the heat excessive; for this remedy, prudently administered, makes the tumour ripen kindly, because nature has always a great abhorrence of a turbulent state.

Continual FEVERS.—There is no disease to which the useful precept, *principiis obsta*, is more applicable than to fevers; because in the beginning it is generally easy to do good; but when the distemper has gained ground, the cure is often attended with difficulty: for a medicine, which early administered might have prevented the impending danger, frequently fails when the bodily strength is exhausted by the violence of the disease. However, a patient who applies late for assistance, is not to be abandoned to his fate; since it is certain, that those diseases, which in old times were ascribed to the divine wrath, are frequently cured by natural means, even when they appear most desperate: wherefore the physician ought to lay it down as an absolute rule, never to be wanting in his duty.

And first, as blood-letting is a most excellent remedy in the beginning of all fevers; if it has happened to be neglected for some days, let us consider whether it is still proper to be ordered.

In case of intolerable pain in any part of the body, of difficulty of breathing, or a delirium, blood is to be taken away, according to the patient's strength; with the lancet, if he be able to bear it; if too weak, by cupping; but if excessively so, by leeches: and if this may be done when the disease has got to the height, it ought, for stronger reasons, to take place in the beginning: and let me observe by the way, that leeches are often of vast service in a delirium. I have also sometimes found, by experience, that pieces of lambs lungs, applied warm to the head, have carried off the phrenzy, by the exudation of the noxious or superfluous humour.

FEVERS attended with Eruptions, the chief of which, after the small-pox, measles, and plague, is the miliary fever, than which no fever puts on more various appearances. Pustules, rough to the touch, break out sooner or later all over the body; sometimes red, sometimes whitish, and again both

forts intermixed; at one time smaller, at another larger and more elevated, and of a bad smell. Sobs and anxiety about the heart are very frequent symptoms, which are often followed by a delirium and convulsions. The disease runs into a considerable length; and if it happens to end too soon, without a sufficiently perfect crisis, it often brings on a bad habit of body. The red pimples are not so dangerous as the whitish; and the more lively their colour, the safer they are. Hence it appears, that this fever is more owing to a defect of the humours, and the animal spirits in particular, than to any bad quality of the air; and that it requires different methods of cure, according to its different circumstances.

But of what kind soever the pustules are, blood is to be drawn in the beginning, if the patient hath strength to bear it; unless he be actually in a sweat, in which case blood-letting is either to be omitted, or at least to be put off for a day or two, or to some other convenient time.

Now red pustules bear bleeding much better than the whitish: and though in both forts blisters are serviceable, yet they are more necessary in the latter; and they are to be applied to the neck, head, and all the limbs, at proper distances of time. After all, I would advise the physician always to bear in mind, that the more sparingly blood has been drawn, the more happily the disease generally terminates: for when the strength has been exhausted by evacuations towards the latter end, the eruption sinks in, and the patient dies.

Nature's endeavours to expel the morbid matter through the skin, are to be assisted by moderately cordial medicines. Of this tribe the most proper are the bezoardic powder, the compound powder of contrayerva, and the cordial confection; adding nitre in case of an inflammation: and this salt may be very advantageously joined to cordial medicines in almost all malignant fevers, at least in the beginning. Toward the decline, warm bathing is sometimes serviceable, in order to bring forth the remains of the pustules.

But if, either at the height, or on the decline of the fever, the only appearance of an eruption is a vast number of pellucid vesicles, so small as hardly to be seen: it is not safe to persist too long in the use of internal medicines of this tribe, unless the length of the distemper has so far weakened the patient, as to render even more powerful cordials necessary: for such little roughnesses of the skin are not able to bring on a good crisis, but on the contrary, generally denote a difficult and tedious illness; wherefore, without discontinuing the blisters, the cause of the disease is to be carried off by other ways, especially through the intestinal canal by gentle purges of rhubarb, or manna and Glauber's salts.

It is to be observed, that this disease is not always terminated by any one sort of crisis; it has some-

times one sort, sometimes another; and, in some cases, several forts together, as frequently happens in other malignant fevers. Thus, at the same time that there are other discharges of the morbid matter, a thrush sometimes breaks out, and spreads all over the mouth and throat. This commonly begins with a hiccup; and if it be whitish and very moist, and occasion a plentiful spitting, it is so far from portending any great danger, that it is a sign of the distemper's ending happily; but if it be of the black kind and dry, and the spittle rough and little in quantity, it is a fatal omen, as it indicates the mouth and throat choked up with slimy phlegm. In these cases, it is proper to use gargles made of barley-water and syrup of mulberries, or some such other fyrrup, or the pectoral decoction: for repellents of all kinds are to be carefully avoided.

It may possibly seem strange to some, that Sydenham prescribes the bark in this fever, and the apothecary attending it, who says, he always found it to answer his expectations. But this was not a rash practice in that sagacious physician; for this fever often intermits when the apothecary do not appear; but it more frequently ends upon their going off. In both cases this excellent antidote is of very great service. Sydenham was the first, among us, who described this fever; which, he says, took its rise here in the month of February 1684, after the long severe frost of the preceding winter. Hence it is probable, that it arose from the acrimony of the humours, induced by the constriction of the fibres of the skin from cold, and the consequent diminution of perspiration.

The Petechial Fever.—The petechæ, from which this fever has its name, are broad red spots, like the bites of fleas, not rising above the surface of the skin. When they are livid or black, they are of very dangerous prognostic; because they are really so many little gangrenes; and therefore, the more numerous they are, the more their consequence is to be dreaded.

The common practice of giving hot medicines in the beginning of this distemper, in order to raise sweats, is quite wrong. It is much the safer way to check the gangrenous dispositions of the humours by the bezoardic powder, or rather the compound powder of contrayerva, with nitre, as is before mentioned; or to assist nature with the cordial confection dissolved in simple alexeterial water; and also to adulterate the patient's drink with dulcified spirit of nitre; to repair his strength with Rhenish wine; and, in fine, a very proper drink will be barley-water with juice of lemons: and all these liquors are to be drank plentifully. It will likewise be of use sometimes to administer some doses of the calx of antimony and bezoardic powder mixed, in order to provoke sweat; but the calx should not be too much washed: yet it is necessary to admonish, that it is not an uncommon case, especially towards the

latter end of the disease, that the patient's weak low state requires, warmer cordials; such as Virginia snake-root, contrayerva-root, the root of wild-valerian, saffron, and the like: and infusions of these in water will be far more convenient than any other powder, especially if they be mixed with a small quantity of distilled vinegar.

Intermitting FEVER.—That this is not carried off by the Peruvian bark with a proper degree of certainty, without premising a vomit or a purge, or both, is not unknown to physicians; but to join some mild cathartic to this remedy will perhaps appear new in practice: for it is commonly thought, among us, that this medicine has little or no effect, unless the patient be costive while he takes it: but long experience has taught me, that it is quite necessary to add a small quantity of rhubarb to this febrifuge, so as to procure two stools at least every day: nor have I ever observed that this procedure has lessened its virtue, but rather rendered it more efficacious; for although strong irritating cathartics raise such disturbances in the blood and humours, as make the proper medicines ineffectual; yet moderate purging is attended with this good effect, that the stomach better digests whatever is taken in, whether medicines or food; whereby their finest and most wholesome parts pass into the mass of blood.

The occasion of my contriving this method of giving the bark was this: about five and thirty years ago, intermettent fevers, of a worse sort than ordinary, were very rife, and frequently terminated in a bad habit of body, and even in a dropsy; which consequences, when I had maturely considered, I thought that this method might probably guard against them; nor was I deceived in my opinion: and the success with which it was attended, encouraged me to pursue it, whenever this disease attacked bodies loaded with gross humours: but I was well aware of the danger of purging too much; for after having given a drachm or two of rhubarb in this manner, it was my usual custom to omit the purgative, and continue the use of the febrifuge alone: and, besides the advantages already recited, I made this observation, that when the disease is carried off by this method, there is always less danger of a relapse.

Now, with regard to this noble medicine, I have this one admonition to give, that it is not proper in any other fevers but those of the intermittent kind: for in continuals it is so far from being of service, that it does much mischief; and it is also pernicious in those hectic which are accompanied with ulcers of any kind of the internal parts; though they often have periodical returns, and much resemble quotidian or tertian intermittents: whence it may not perhaps appear an improbable conjecture, that this medicine operates on the bile alone; for that the

bile has a considerable share in causing intermitting fevers I have not the least doubt.

However, it sometimes happens that this febrifuge fails in true intermittents; which failure is generally owing to a bad habit of body: wherefore the physician should use his best endeavours to discover in what part the fault lies, and it will be commonly found to be in the viscera and glands of the abdomen: upon this account it will be necessary to prescribe some purges, and sometimes vomits; and in the intermediate days deobstruents and stomachics, the best of which are aromatic bitters and preparations of steel: and for the same reason it is, that quartans are of more difficult cure than any other intermittents; for in these the blood and humours are inert and excessively viscid; so that there are two diseases to be conquered together, the bad habit of body and the fever; which is generally done effectually, by joining Virginia snake-root and steel with the bark: however, it may not be improper to take notice, that in some cases where the bark did not answer, I have taken off intermitting fevers with a powder composed of chamomile flowers, myrrh, salt of worm-wood, and a little alum.

But there is more danger attending that sort of intermitting fevers, by the Greeks named *μυρτι-ταιος*, that is, semitertian. This fever returns every third day; and of forty-eight hours the fit commonly takes up about thirty-six, more or less; nor does the fever go off entirely, but only remits between the paroxysms. Hence Galen was right in saying, that it was compounded of a continual, quotidian, and an intermitting tertian.

Thus a particular regard is due to this disease, which seems to be caused by an inflammation of some internal parts, accompanied with obstructions from bilious humours and too viscid lymph: wherefore blood is to be drawn once or oftener, according to the patient's strength; and gentle purgatives, such as the diuretic salt, manna with Glauber's salt, and the like, are to be ordered and repeated at proper distances of time; nor ought we to be hasty in giving the bark, for fear it should increase the inflammation by adding to the obstruction of the viscera, and bring on a hectic. It will be much safer, first, to order the saline draughts, with juice of lemons, salt of wormwood, and simple cinnamon-water, to be taken frequently.

Epidemic FEVERS.—These are caused by some fault in our ambient air; and that is chiefly owing to the excess of heat, cold, drought, or moisture, or to the unseasonable vicissitudes of these qualities.

In Greece and Asia, where the seasons are generally uniform, and the winds pretty regular for certain but different quarters in the different months of the year, it was easy for men of sagacity to observe the changes of the weather, with their good and bad effects.

effects: and on a long use of this method of observation was built the art of prognostic in diseases, wherein Hippocrates, the father of physic, first excelled.

But in our climates, such is the inconstancy of the weather, and so many are the causes that raise different and even contrary winds on a sudden, that it seems impossible to erect any solid superstructure on that foundation: and accordingly Sydenham, who, in imitation of Hippocrates, attempted to describe the fevers of each respective year, and to account for their differences from the differences of the weather and seasons, found at length "That he had made no progress in discovering the causes of epidemical diseases by observing the manifest qualities of the air; as having remarked that in different years, which agreed perfectly well in the visible temperature of the air, the reigning diseases were very different, and so on the contrary; and likewise, that there are various constitutions of years, which depend not on heat, cold, drought, or moisture, but on some occult and inexplicable alteration in the very bowels of the earth."

Now this matter, in my opinion at least, stands thus: that the manifest qualities of the air have a considerable share in producing epidemic diseases, is a point that admits of no doubt; but there are other conjunct causes which alter the force of those qualities, either by increasing or diminishing them. These chiefly spring from the earth, as Lucretius wisely said:

— ubi putorem humida nocte est,
Intempestivis pluvisque et solibus ista.

When she's grown putrid by the rains and sweats
Such noxious vapours, press'd by scorching heats.

Now as this terrestrial putridity is chiefly occasioned by rotted vegetables, and sometimes also by the dead bodies of animals, and by minerals; so the waters, especially of lakes and morasses, which have their plants and animals, in the same manner frequently exhale pestilential vapours, which infect the circumambient air. In this class may be ranged, though rarely happening in our climates, inundations, earthquakes, eruptions from mountains, and all other remarkable and uncommon phenomena of nature, which are capable of filling the air we breathe, with particles offensive to animal life: for these affect our bodies, and prepare them for the easy reception of diseases.

Slow or hectic FEVERS.—These are owing to so many different causes, that they may well seem not to be the same, but different diseases. Of all this tribe, the most pernicious are those which arise from an ulcer in any particular part of the body, the lungs especially, by the purulent matter mixing with the blood, and disturbing its natural motion.

Bilious or Choleric FEVER, a species of acute fever, owing its origin to distemperatures of the bile.

The general signs of the bilious or choleric fever, are a remarkable anxiety, and frequent complaints about the breast, as of a straitness and painful heat. A violent heat on the inside of the mouth, and insatiable and intolerable thirst, trembling and convulsive motions of the joints, and violent deliriums. Dryness of the mouth and tongue are often so terrible in this disease, that the skin cracks with it; and often the whites of the eyes, sometimes the whole body, becomes yellowish. The peculiar and appropriated symptoms of a choleric febris, strictly so called, are an universal languor and debility of the limbs.

A severe shivering first seizes the patient, and is soon succeeded by a very violent heat, and raging pain in the head; and, after the two first days, there usually are very terrible strainings and reachings to vomit. The matter brought up at these times is caustic, acrid, and bilious, and inflames and even ulcerates the fauces; and, if voided upon a stone floor, effervesces violently. In this vomiting abates, there immediately comes on a diarrhoea attended with a tenesmus, occasioned by the irritation of this sharp matter in the rectum. Faintings also are very frequent in this disease, especially where the vomitings do not bring up a sufficient quantity of the offending matter. The peculiar and appropriated signs of the causes, strictly so called, are these: a violent and insatiable thirst, greater than that in any other fever. The bowels are always bound, and it is but very seldom that there is any tendency to vomit. The urine is reddish and turbid, and, after standing some time, deposits a red sediment. Often there is a sensible pain and soreness in the præcordia, so that the patient cannot bear the least touch upon the breast; and usually, in the course of the disease, there are faintings and violent convulsions.

Persons most subject to this disease are such as eat largely, and drink heavy and imperfectly fermented liquors after it. The choleric febris, properly so called, is most frequent with those of a cholericosanguineous habit, and such as feed on high-seasoned meats, and drink abundance of wine or other strong liquors; and is often brought on such persons by their falling into violent passions after a full meal. The cause peculiarly attacks the people of melancholic habits, who are much inclined to passion, but suppress it, and who are naturally costive.

Method of cure.—The cure of these diseases consists in the mitigating the violent sharpness of the humour, and promoting its evacuation; and, finally, in abating the burning heat brought on by it. The utmost endeavours are first to be made to correct and alter the morbid matter. To this purpose the several preparations of nitre, with the testaceous powders and mucilaginous pitans, with
final

small mixtures of lemon-juice, and frequent draughts of cooling and diluting liquors, are to be given moderately warm. If the costiveness be too violent, clysters of broth must be injected, with the addition of a little oil and salt; and, if necessary, small doses of rhubarb. To quell the febrile heat and emotion of the blood, the mistura simplex may be given with great success; and there is often a sensible good effect from the application of rags, wetted in camphorated spirit of wine, to the pit of the stomach. After the morbid matter is evacuated, the reachings to vomit may be allayed by gentle opiates. All hot medicines change the bilious fevers into inflammatory ones, and the common sudorifics drive the morbid matter into the blood, and usually bring on almost immediate discolourings of the skin, like those of the jaundice. Bleeding, though performed ever so early in the disease, seldom does any good, except only in remarkable plethoric habits.

Colligative FEVER is that in which the body is much emaciated and consumed in a short space of time: the solid parts, and the fat itself waste, sometimes by a diarrœa, sometimes by sweat, by urine, or by feverish heats alone, without any sensible discharge. A colligative fever is observed to accompany a cancer of the breast, with a diarrœa. See the articles *DIARRHOEA*, *DIABETES*, *CANCER*, &c.

For this disease, emulsions of almonds, and of the four cold seeds, as also asses, goats, or woman's milk are proper; or cow's milk with the juice of water-creffes; chicken broth, broth made of river crabs, or wood snails bruised.

Diary FEVER, the same with *ephemera*. See *EPHEMERA*.

Gael or Camp FEVER. See *GAOL*.

Hospital FEVER. See *HOSPITAL*.

Yellow FEVER. See the article *Bilious FEVER*.

FEVERFEW, *matricaria*, in botany, a genus of umbelliferous plants, whose flowers are compound and radiated, the hermaphrodite florets, which compose a hemispherical disc, are numerous and tubulose, and contain each five capillary stamina; the female corollulæ, which form the rays, are ligulated, and contain a filiform style, terminated by two revolved stigmas; the seeds are oblong, naked, and solitary, being contained in the cup, and placed on a convex naked receptacle.

The common feverfew has a white fibrous root, from which issues forth the stalks, which are round, striated, branching, and full of a spongy pith; the leaves are of a light green colour, composed of three pair of lobes, which are cut into many segments, and terminated by an odd one. It flowers in June, and the seeds are ripe in autumn.

The whole plant has a very strong smell; it is biennial, and grows wild in hedges and uncultivated places in many parts of England.

The leaves and flowers of feverfew is reckoned excellent in hysseric and uterine disorders. It is certainly a very good carminative, discusses wind, strengthens the stomach, and helps digestion.

FEUILLANS, an order of barefooted monks, who observe the same rules with the Bernardines. See *BERNARDINES*.

FIAT, in law, a short order or warrant signed by a judge, for making out and allowing certain processes.

FIAT JUSTITIA, is where the king, on a petition to him for his warrant, to bring a writ of error in parliament, writes on the top of it, *fiat justitia*, "let justice be done;" upon which the writ of error is made out.

FIBER, the bever, in zoology, is made, by *Linneus*, a species of castor. See the article *BEAVER*.

FIBRE, in anatomy, a perfectly simple body, or at least as simple as any thing in the human structure; being fine and slender like a thread, and serving to form other parts: hence some fibres are hard, as the bony ones; and others soft, as those destined for the formation of all the other parts.

The fibres are divided also, according to their situation, into such as are straight, oblique, transverse, annular, and spiral; being found arranged in all these directions, in different parts of the body; for an account of which see *BONE*, *MUSCLE*, *NERVE*, *ARTERY*, *VEIN*, &c.

FIBRE is also used to denote the slender filaments which compose other bodies, whether animal, vegetable, or mineral; but more especially the capillary roots of plants. See *PLANT*, *WOOD*, &c.

FIBRILLA, a term sometimes used for a very minute or slender fibre.

FIBROSE, something consisting of fibres, as the roots of plants. See *ROOT*.

FIBULA, in anatomy, the outer and smaller bone of the leg, called also *perone*. It is nearly of a triangular figure, and stands parallel to, but distant from, the tibia, or inner bone of the leg. Its upper extremity does not reach to the os femoris, but is only joined to the external side of the tibia; and its lower extremity, called *malleolus externus*, concurs in the articulation of the tarsus, which its eminence serves to strengthen, by rendering a luxation less easy. It has no particular motion of its own, but wholly follows that of the tibia.

FIBULÆUS, a muscle of the leg, more usually called *peronæus*. See *PERONÆUS*.

FICUS, the fig-tree, in botany, a genus of polygamious plants, producing male and female apetalous flowers; the stamina are three setaceous filaments, topped with twin anthers, and the female flowers have an inflexed style, terminated by two acuminate reflexed stigmas: the fruit is a large fleshy turbinate receptacle, the interior sides of which support the flowers, which are inclosed within

within it; and is properly nothing but a common calyx, or cup of the fructification.

Fig trees are propagated either by layers or suckers; those which are layed from fruitful branches are to be preferred, for those which are raised from suckers are generally spongy, and are not only apt to produce little or no fruit, but being fuller of sap than the layers are also liable to suffer by frosts in this climate. With us fig-trees are generally planted and trained against walls, but they will do very well in standards, they may also be planted in espaliers, where their large leaves will entirely hide disagreeable objects; and in order to secure them from being damaged in severe frosts, this is a very convenient form for protecting them with reed panels, mats, &c. This last method we think the best, as they will produce greater quantities of figs than those against walls, which frequently come out before the severity of the season is over.

The season for pruning fig-trees is either in autumn or the spring, we think the month of February the best, as at that season it is discoverable what branches have escaped the winter, when they may be pruned accordingly, training them regularly at about a foot asunder, but they should not be shortened, as the fruit is produced at the extremities of the branches; though it is not amiss, where the branches are luxuriant, to pinch the end off, this will cause them to bleed, and may be a means of checking their growth, so as to produce branches more fit for bearing.

Fig-trees generally produce two crops in Italy and other warm countries; the first crop is little regarded, for it is the second crop of figs that are produced from the shoots of the same year which is their principal crop; but these rarely ripen in England, as it must be an extraordinary fine autumn to have them fit to eat in November with us. The inhabitants up the Levant are very curious in the culture of their figs, for, without much pains, their fruit falls off and comes to nought, Tournesort, in his Travels, says that Pliny observed "that in Zia they used to dress the fig-trees with much care, and still continued to do so". To understand right this husbandry of figs (called in Latin *caprificatio*), we are to observe, that in most of the Archipelago islands they have two sorts of fig-trees to manage, the first is called *ornos*, from the old Greek *erinos*, a wild fig-tree, or *caprificus* in Latin; the second is the domestic or garden fig-tree: the wild sort bears three kinds of fruits, fornites, cratitires, and orni, of absolute necessity towards ripening those of the garden fig. The fornites appear in August, and continue till November without ripening; in these breed small worms which turn to a sort of gnats, no where to be seen but about these trees; in October and November these gnats of themselves make a puncture into the second fruit, which is called cratitires, and do not shew themselves till towards

the end of September; and the fornites gradually fall away after the gnats are gone; the cratitires on the contrary remain on the tree till May, and inclose the eggs deposited by the fornites when they pricked them in May. The third sort of fruit begins to put forth from the same wild fig-trees which produced the other two; this is much bigger, and is called orni; when it grows to a certain size, and its bud begins to open, it is pricked in that part by the gnats of the cratitires, which are strong enough to go from one fruit to the other to discharge their eggs.

It sometimes happens that the gnats of the cratitires are slow to come forth in certain parts, while the orni in those very parts are disposed to receive them; in which case the husbandman is obliged to look for the cratitires in another part, and fix them at the end of the branches of those fig-trees whose orni are in a fit disposition to be pricked by the gnats; if they miss this opportunity, the orni fall, and the gnats of the cratitires fly away: none but those that are well acquainted with this sort of culture know the critical minute of doing this; and, in order to it, their eye is constantly fixed on the bud of the fig, for that part not only indicates the time that the prickers are to issue forth, but also when the fig is to be successfully pricked; if the bud be too hard and too compact, the gnat cannot lay its eggs, and the figs drop when this bud is too open.

These three sorts of fruit are not good to eat, their office is to help to ripen the fruit of the garden fig-trees in the following manner: during the months of June and July the peasants take the orni at a time that their gnats are ready to break out, and carry them to the garden fig-trees; if they miss the moment, the orni fall, and the fruit of the garden fig-tree not ripening, will in a very little time fall in like manner. To conclude, the peasants so well order the orni, that their gnats cause the fruit of the garden fig-tree to ripen in the compass of forty days. Tournesort says, "I could not sufficiently admire the patience of the Greeks, busied above two months in carrying these prickers from one tree to another; I was soon told the reason; one of their fig-trees usually produces between two and three hundred pounds of figs, whereas those of Provence seldom above twenty-five." These figs are very good green; when they would dry them, they lay them in an oven to keep them the rest of the year. Barley bread and dried figs are the principal subsistence of the boors and monks of the Archipelago; but these figs are very far from being so good as those dried in Provence, Italy, and Spain. The prickers contribute perhaps to the maturity of the garden fig, by causing to extravasate the nutritious juice, whose vessels they tear asunder in depositing their eggs; perhaps too, besides their eggs, they leave behind them some sort of liquor proper to ferment

ment gently with the milk of the fig and to make their flesh tender; for the figs in France ripen much sooner by having their buds pricked with a straw dipped in olive oil. The particulars of these circumstances are confirmed not only at Zia, Tinos, Mycone, and Scio, but in most of the other islands of the Archipelago.

FIDD, among sailors, a piece of wood or iron thrust through a hole in the foot of the top-mast, after it is drawn up to its utmost height. See **MAST** and **TRUSSEL-TREES**.

In the article **CAP** we observed, that it was used to keep steady the top-mast above the frame of the top, as it is kept steady below by the trussel-trees: the fidd rests upon the trussel-trees, and with it of course the whole weight of the top-mast: the fidd-hole is therefore just above them when the top-masts are erect.

FIDDLE-WOOD. See the article **CITHAREXYLUM**.

FIDE JUSSOR, among civilians, the same with a surety. See **SURETY**.

FIELD, *campus*, in agriculture, a piece of ground inclosed, whether for tillage or pasture. See **TILLAGE** and **PASTURE**.

FIELD, in heraldry, is the whole surface of the shield, or the continent, so called because it containeth those achievements anciently acquired in the field of battle. It is the ground on which the colours, bearings, metals, furs, charges, &c. are represented. Among the modern heralds, field is less frequently used in blazoning than shield or escutcheon. See **SHIELD**, &c.

FIELD BOOK, in surveying, that wherein the angles, stations, distances, &c. are set down. See **SURVEYING**.

FIELD COLOURS, in war, are small flags of about a foot and a half square, which are carried along with the quarter-master general, for marking out the ground for the squadrons and battalions.

FIELD-FARE, in ornithology, the English name of the variegated *turdus*, with a hoary-head. See the article **TURDUS**.

It is larger than the common black-bird, and with us is a bird of passage, coming over in great numbers in the winter.

FIELD-FORT, in fortification. See **FORT**.

FIELD-OFFICERS, in the art of war. See the article **OFFICER**.

FIELD-PIECES, small cannons, from three to twelve pounders, carried along with an army in the field. See **CANNON**.

FIELD-STAFF, a weapon carried by the gunners, about the length of a halbert, with a spear at the end; having on each side, ears screwed on, like the cock of a match-lock, where the gunners screw in lighted matches, when they are upon command; and then the field-staffs are said to be armed.

FIELD-WORKS, in fortification, are those thrown up by an army in besieging a fortress, or by the besieged to defend the place. Such are the fortifications of camps, highways, &c.

Elysian FIELDS. See **ELYSIAN**.

FIERI FACIAS, in law, a writ that lies where a person has recovered judgment for debt or damages in the king's courts against one, by which the sheriff is commanded to levy the debt and damages on the defendants good and chattels.

FIFE, in music, is a sort of wind-instrument, being a small pipe. See **PIPE**.

FIFTH, in music, the same with diapente. See the article **DIAPENTE**.

FIG, the fruit of the ficus or fig-tree. See the article **FICUS**.

Figs, as well fresh as dry, are very wholesome food; they are nutritive and emollient: they are also good in disorders of the breast and lungs; but a too free use of them has sometimes brought on obstructions of the viscera, a common complaint in the Levant. They are frequently made ingredients in our pectoral decoctions, and by some are greatly recommended against nephritic complaints. They are much used externally by way of cataplasm, either roasted or boiled in milk, for the ripening of tumours, and for easing the pain of the piles.

FIG-MARIGOLD. See **MESEMBRYANTHEMUM**.

Indian FIG. See **OPUNTIA**.

FIG, in farriery, a sort of wart on the frush, and sometimes on the whole body of a horse. The figs that appear on the frush, or sole, make an evacuation of malignant stinking humours, that are very hard to cure.

FIGHT. See **BATTLE**.

Sea-FIGHT implies, in general, an engagement, either between fleets of men of war, fleets of galleys, or single ships.

The ancient Greeks, in preparing for an engagement at sea, made it their first business to disburthen their ships of war of all provisions, and other lumber not necessary in the action, lest by too heavy a load they should be rendered unwieldy, and unfit for service, being neither able with force and vigour to assail their enemies, nor by lightly tacking about to avoid their onsets. This done, when the enemy appeared in view, they took down their sails, lowered their masts, and secured whatever might expose them to the winds, chusing rather to be governed by oars, which they could manage at their pleasure.

As to their order of battle, that was varied as time, place, and other circumstances required; being sometimes formed like an half-moon, and called *σολος μηνειδης*, the horns jutting out towards the enemy, and containing the ablest men and ships; sometimes, on the contrary, having its belly nearest the enemy, and its horns turned backwards, whence it was termed *κρητη παραταξις*: nor was it unusual

to range them in the form of a circle, which they called *κυκλὸν ποταλὸν*; or, to mention no more, in the figure of the letter V, with the horns extended in a direct line, and meeting at the end; which order was named *εὐκαταπὴς παρατάξις*; in Latin, *forceps*; and was usually encountered by the enemies ranged into the same order inverted, whereby they resembled the figure of a wedge or beak, whence it was called *cuneus* or *rostrum*; this enabled them to penetrate into the body of the adverse battle.

Before they joined battle, both parties invoked the gods to their assistance by prayers and sacrifices; and the admirals going from ship to ship in some of the lighter vessels, exhorted their soldiers in a set oration, to behave themselves like men: then, all things being in readiness, the signal was given by hanging out of the admiral's galley a gilded shield, as we read in Plutarch; or a red garment or banner, which was termed *αἶψιν σημαία*. During the elevation of this the fight continued, and by it depression, or inclination towards the right or left, the rest of the ships were directed in what manner to attack their enemies, or retreat from them. To this was added the sound of trumpets, which was begun in the admiral's galley, and continued round the whole navy. It was likewise usual for the soldiers, before the fight, to sing a psalm, or hymn, to Mars; and after the fight, another to Apollo.

The fight was usually begun by the admiral-galley, as we find done at the battle of Salamis, and another time by Attalus's ship: it was carried on in two different manners, for not only the ships engaged one another, and by their beaks and prows, and sometimes their sterns, endeavour to dash in pieces, or overset and sink their opposers, but the soldiers also annoyed their enemies with darts and slings; and upon their nearer approach, with swords and spears. Thus Lucan:

*Ut primum rostris crepuerunt obvia rostra,
In puppim rediere rates, emissaque tela
Æra texerunt vacuumque cadentia pontum.*

The ships first meeting shew their fiercest rage,
And furiously with clashing beaks engage;
These turn about, and then the javelins fly,
And show'rs of arrows darken all the sky;
The sea is cover'd o'er.—

We find by the same author, that after this first onset, their ships approached so near each other as to be linked together with chains or grappling-irons, and then they fought with sword in hand. Sometimes for want of irons they so fixed their oars, as thereby to hinder their enemies from retreating; so we read in Lucan:

Seque tenent remis, toto stetit æquore bellum.

The ships they hold with oars, and all around
The face of horrid war appears.—

This sort of combat was not unlike a siege, where the stronger party, prevailing over their enemies, entered their vessels by laying bridges between them, and having killed, or taken prisoners, all they found in arms, seized and dragged away their ships.

When a town was besieged by sea, they used to environ its walls and harbour with ships, ranged in order from one side of the shore to the other, and so closely joined together by chains and bridges, on which armed men were placed, that, without breaking their order, there could be no passage from the town to the sea; this leaguer Diodorus calls *ἐσφυμα*. The better to prevent any attempts of the besieged, Demetrius is said to have invented a sort of boom armed with spikes of iron, which swam upon the waters; this he placed at the mouth of the harbour of Rhodes, when he besieged that city. Sometimes they blocked up the harbour, or made a passage to the town by raising a vast mole before it, as we read of Alexander in the siege of Tyre; or by sinking ships filled with stones and sand, as we find practised by the Romans.

The attacks were usually carried on by men standing upon bridges between the ships, and thence with darts and stones forcing the besieged from their walls: thus Alexander, in the siege of Tyre, so ordered his galleys, that two of them being joined at the heads, and the sterns somewhat distant, boards and planks were laid over in the fashion of bridges, for soldiers to stand upon, who were in this manner rowed close to the wall, where, without any danger, they threw darts at their enemies, being sheltered behind the fore-decks of their own galleys. Here, also, that they might throw their missile weapons with greater advantage, and batter the walls with their rams and other engines, they erected towers so high as to command the city walls, from which having repelled the defenders, they by this means had opportunity to defend by ladders.

The besieged were not at a loss for ways of defeating the stratagems; the ships linked together they pulled asunder with iron-hooks, the passage to the town they blocked up in the same manner the enemies had done that of the harbour, or otherways; if they could not hinder their approach, they failed not to gall them with darts, stones, fire-balls, melted pitch or metals, and many other things; and, lastly, to trouble you no farther, it was frequent for those in the town to destroy the vessels and works of the besiegers by fire-ships, as we find done by the Tyrians, who, taking a large vessel, put a great quantity of ballast into the stern, covered the head with pitch, tar, and brimstone, then by the help of sails and oars brought her close to the Macedonian fortrefs, where having set the combustible matter on fire, they retreated into boats prepared for that purpose; the fire immediately seized the towers of the fortification, and by the help of
torches

torches and fire-brands cast by those in the boats, the work itself took fire, and that vast pile, on which so much time and labour had been bestowed, was in a few moments quite demolished. The use of fire-ships we likewise meet with amongst the Rhodians in Diodorus the Sicilian.

We have observed above that the ancients ranged their ships or galleys so as to present them in front to their enemy; because the machines they then made use of, were fixed in the heads or prows of their vessels: the same reason now prevails with regard to the galleys, which are drawn up in the form of a crescent, or half-moon, whose ends or horns are opposed to the enemy; in the middle of which is the admiral, from whence, he the more distinctly observes the motions of his fleet throughout. The two fleets being thus drawn up, approach each other to a convenient distance, when the battle beginning at the ends of the half-moon, extends insensibly till the whole fleet is engaged, and each partake of the danger and glory of the action. See compartment of plate LVI.

In an engagement of ships of war, the fleets are drawn up in two parallel lines upon a wind. The ships keep close to the wind on the line they are formed in, and are commonly at a cable's length distance one from the other; the fire-ships, transports, tenders, &c. keeping at half a league distance on the opposite side of the enemy. Thus the fleets AB and CD, that are engaged, are ranged under an easy sail, close to the wind; and the fire-ships EE, of the fleet AB, are to windward; the fire-ships FF, are to the leeward of their fleet CD. This form was observed, for the first time, in the famous battle of the Texel, where the duke of York defeated the Dutch, on the 13th of June, 1665. See SQUADRON and LINE.

It is probably the most expedient method, as proved by experience, to keep a constant fire on the enemy, by firing in platoons, which will have a much greater effect, and distress them more, than the common received notion of broad-side and broad-side with some intervals between, which is generally the case in most actions; in order to which, I would divide the guns into five fires, in the following manner, viz. half the guns abaft below, then half the guns abaft aloft, so the other half below forward; and, lastly, the quarter-deck guns, and those on the fore-castle: so that, by the time your first platoon is fired, you will be able to keep up a constant fire on your enemy; which method I prefer, as I observed before, to broad-side and broad-side, where chance has often a greater share in the execution than judgment; notwithstanding, this last method is sometimes necessary, as time and circumstances may offer. I would likewise advise you to point your guns so as to make a breach in your enemy's ship.

The chief judgment of an admiral, is to form his line in a proper disposition and strength from the van

throughout to the rear; in doing which, particular regard must be had to make the center strong, for if that is forced, or broke through, the battle is looked upon as lost. Here it is to be observed, that, in a sea-action, the center is made the strongest, whereas, in a land-fight, it is the weakest; and the wings of an army are strongest, lest the enemy, by forcing a wing, should have the advantage of flanking, and consequently putting the line in disorder: for the same reason also, the van and rear of a fleet is not put into confusion, because care is taken to make them proportionably strong to resist the enemy: therefore the weakest part of the line will be in the quarters, supported each way from the center throughout.

The signal being made for battle, each division, every captain crowds into his proper station without loss of time: they endeavour to approach each other till within point-blank gun-shot, which is near enough for a line of battle; for if you should be too near, your line will naturally fall into a curve, notwithstanding all your endeavours to the contrary; besides, you cannot so well observe your own line: the enemy may intercept your sight, especially if the line be long, which may cause a mistake in the signals. It would be better for the contending admirals in chief, that each had a view of his own line, as well as of that of the enemy, in order to make proper signals, and, if any distress happen, to be the better able to relieve, or if any advantage, to improve upon it.

The battle being begun, the fate of war decides the day. In a word, the success of all depends upon placing your shot well, and preserving a proper disposition in the line. There is one maxim, by which we should always be guided, that is, that bravery and resolution are absolutely necessary in the first sort of engagement, viz. between single ships; and conduct and bravery in the second sort, viz. that between two squadrons.

Conduct and presence of mind are chiefly requisite in a line of battle; for the admiral cannot be supposed to want bravery and resolution. It is then he must summon up all his knowledge and experience, to judge of the strength of his line; when and how to keep it as complete as possible, by ordering ships from the corps-de-reserve, or by changing ships from one part of the line to the other; or by detaching from one part of the wings, which may not be so much pressed, to that which is. Here he must also consider the position of his enemy; his eye must be on him, as well as on his own line, from the van to the rear; and all should strictly mind the admiral's motions, signals, &c. Boats will, in all probability, be continually passing from the ships to their flag-officers, if any thing extraordinary should happen, to acquaint them of it; and from the admirals or commanding officers of each division to the admiral in chief, giving an account of the state and condition

dition of each division, which will be a great satisfaction to him, as he will then be better able to judge how to assist where most wanted if occasion, or how to improve upon any advantage gained.

The battle drawing to a conclusion, it is easy to judge what the conqueror will do to improve his victory; as necessary a part of an officer as any in the action, as it requires great judgment and readiness of thought; and the other, in making his retreat, should let slip no opportunity to save as many of his fleet as he possibly can. His eye must be quick, and his judgment and presence of mind as ready as at the first onset of the battle. He has no other resource left but in his escape, and this comfortable alleviation of his defeat, that a glorious retreat may gain him as much honour as the victory did to the conqueror.

FIGURAL, FIGURATE, or FIGURATIVE, a term applied to whatever is expressed by obscure resemblances. The word is chiefly applied to the types and mysteries of the Mosaic law; as also to any expression which is not taken in its primary and literal sense.

FIGURAL, or FIGURATIVE NUMBERS, are such as do or may represent some geometrical figure in relation to which they are always considered, as triangular numbers, pentagonal numbers, pyramidal numbers, &c.

FIGURATIVE, among grammarians, is the same with what is otherwise called characteristic. See **CHARACTERISTIC**.

FIGURATIVE COUNTERPOINT, in music, is that wherein there is a mixture of discords along with the concords. See the article **COUNTERPOINT**.

FIGURATIVE DESCANT, in music. See the article **DESCANT**.

FIGURE, in philosophy, the surface or terminating extremities of any body.

FIGURE, in astrology, is applied to the description, state, and disposition of the heavens at a certain hour, where the places of the planets and stars are marked in a figure of twelve triangles called houses, with regard to the horoscope to be drawn from it. They likewise call it horoscope and celestial themis.

FIGURE, in conic sections, according to Apollonius, is the rectangle of the latus rectum and transversum in the hyperbola and ellipsis. De la Hire calls the rectangle of any diameter and its proper parameter, in the hyperbola and ellipsis, the figure of that diameter.

FIGURE, in dancing, denotes the several steps which the dancer makes in order and cadence, considered as they mark certain figures on the floor.

FIGURE, in fortification, the plan of any fortified place, or the interior polygon; of this there are two sorts, regular and irregular; a regular figure is

that where the sides and angles are equal; an irregular is the contrary.

FIGURE, in geometry, the superficies included between one or more lines, of which there are three sorts, as rectilinear, curvilinear, and mixed figures: rectilinear have their extremities all right-lines, as triangles, quadrilaterals, &c. Curvilinear are such as have their extremities crooked, as circles, ellipses, &c. Mixed, are partly right-lines and partly crooked, as a semicircle, segment of a circle, &c.

FIGURES, in arithmetic, are certain characters whereby we denote any number, which may be expressed by any combination of the nine digits, as 1, 2, 3, 4, 5, 6, 7, 8, 9, and 0.

FIGWORT. See **SCROPHULARIA**.

FILAMENT, a small fine fibre or thread, which composes the texture of the flesh, nerves, skin, &c. of an animal: and it is likewise applied to the component parts of vegetables; as also to the fibres belonging to their roots. It is also used to signify that viscid concreted matter, which appears like hairs or threads in urine.

The word is Latin, *filamentum*, which is a diminutive of *filum*, a thread.

FILAMENT, among botanists, that part of the stamina which supports the anthera and connects it with the flowers, and is of different forms and proportions, according to what class the flower belongs to. See the article **STAMINA**.

FILAZER, or **FILACER**, an officer of the Common Pleas, so called from his filing those writs whereon he makes out process.

FILBERT, or **FILBERD**, the fruit of the corylus, or hazel. This species of nuts is more nourishing than the common ones; but is hard to digest. They are however worthy of being propagated in orchards and gardens; which is done by planting them in February.

FILE, among mechanics, a tool used by workmen in metal, &c. in order to smooth, polish, or cut. It is used, in pharmacy, to reduce hard substances to fine particles, whose consistence will not admit of powdering.

FILE, or **LABEL**, in heraldry, consists sometimes of more, and sometimes of fewer points. According to Guillim, it is borne as a charge in a coat of arms: but it is usually the difference or mark of distinction which the elder brother bears in his coat during his father's life-time. Some call the file the upper horizontal line, and the label the point that issues from it.

FILE, in the art of war, a row of soldiers, standing one behind another, which is the depth of the battalion or squadron. The files of a battalion of foot are generally three deep; as are sometimes those of a squadron of horse. The files must be straight, and parallel one to another.

FILIGRANE, or **FILIGREE-WORK**, any piece of gold or silver-work that is curiously done, with grains or drops on the filaments or threads.

FILING, in smithery, the operation of fashioning metalline bodies by means of a file. See **FILE**.

FILIPENDULA, dropwort, in botany, a genus of plants, whose characters are the following.

The root is fibrous and perennial, with glandulous bulbs fastened to it: the leaves are finely jagged, like those of millefoil: the calyx is monophyllous, denticulated, and divided into six or seven segments which are retroflected, or bent backwards: the flowers are hexapetalous or heptapetalous, loosely disposed in panicles on long stalks, which are almost naked: the stamina are numerous, and situated on the reflected margin of the calyx: the fruit is generally round, and contains many seeds compacted together, each of them furnished with its tube.

This plant contains a salt, approaching to that of alum; but it is mixed with a great deal of sulphur. All authors agree that it is very diuretic and aperitive; and is also recommended for the epilepsy and dysentery.

FILIX, in botany, an order of the cryptogamia class of plants, comprehending the fern, horse-tail, adder's tongue, maiden-hair, spleenwort, polypody, &c. See the articles **FERN**, **HORSE-TAIL**, &c.

FILLER-HORSE, one yoked immediately to a cart. See the article **CART**.

FILLET, in heraldry, the fourth part of the ordinary called a chief, which is placed in the chief point of the escutcheon.

FILLET, in painting, gilding, &c. is a little rule or reglet of leaf-gold, drawn over some mouldings; or on the edges of frames, &c. especially when painted white, by way of ornament.

FILLET, in anatomy, the nervous ligament under the tongue, which midwives usually divide with their nail, or a fixpence, immediately after the child's birth: it is most commonly called the frænum.

FILLET, or **FILET**, in architecture, a little square member, or moulding, used in divers places and on divers occasions; but generally as a crowning over a greater moulding. It is called *lista* or *listella* by the Italians: by the French, *reglet*; and by others, *band* and *bandelette*.

FILLET, in the menage, the loins of an horse, which begin at the place where the hinder part of the saddle rests.

FILLING the Sails, in the sea-language, the act of disposing a sail in such a manner, that the wind pressing into the cavity or belly of it shall force the ship forward, or a-head, in contradistinction to backing, which forces her a-stern; and shivering, which makes her remain almost in a state of rest, neither advancing nor retreating. It may appear something remarkable, but is certainly true, that a ship may be forced backward or forward, or may

remain in her place, with any wind, while her stem is all the while directed to one part of the horizon; and these different states of motion or rest may be communicated by backing, filling, or shivering the sails, by drawing the braces on one side, and loosening them on the other. See the articles **BRACE**, **BACKING**, and **SHIVERING**.

FILLY, a term among the horse-dealers, to denote the female or mare colt. See the article **FOAL**.

FILM, in botany, that woody skin which separates the seeds in the pods of plants.

FILTER, or **FILTRE**, in chemistry, a strainer, commonly made of bibulous or filtering paper, in the form of a funnel, through which any fluid is passed, in order to separate the gross particles from it, and render it limpid. This filtre is put into a funnel, with the small end in the vessel for the reception of the filtrated liquor, and then the liquor is poured into the paper, not too much at once, for fear of bursting it. A filtre is also made of a woollen bag, called Hippocrates's sleeve, or one of linen, according to the nature of the liquor to be filtrated.

FILTRATION, in chemistry. See **DEPURATION**.

FIMBRIÆ, denotes appendages disposed by way of fringe round the border of any thing: such are those about the thicker extremities of the Fallopian tubes. See **GENERATION**.

FIMBRIATED, in heraldry, an ordinary with a narrow border or hem of another tincture.

This, in Latin, is called *fimbriatus*; that is, edged or fringed.

FIN, *Pinna*, in natural history, a well known part of fishes, consisting of a membrane supported by rays, or little bony or cartilaginous ossicles.

FINANCES, in the French polity, signify the revenues of the king and state.

FINE, in law, hath divers applications: sometimes it is used for a formal conveyance of lands or tenements, or of any thing inheritable, being *in esse tempore finis*, in order to cut off all controversies. Others define it to be a final agreement between persons, concerning any lands or rents, &c. of which any suit or writ is depending between them in any court.

FINE sometimes signifies a sum of money paid for entering lands or tenements lett by lease; and sometimes a pecuniary mulct for an offence committed against the king and his laws, or against the lord of the manor.

FINE adnullanda levato de tenemento quod fuit de antiquo dominico, is a writ to the justices for disannulling a fine levied of lands holden in ancient demesne to the prejudice of the lord.

FINE capiendi pro terris, &c. a writ lying for one that, upon conviction by a jury, having his lands and goods taken into the king's hands, and his body committed to prison, obtains favour for a sum of money,

money, &c. to be remitted his imprisonment, and his lands and goods to be redelivered to him.

FINE Force, an absolute necessity that is unavoidable, whereby one is compelled to do any thing.

FINE levando de tenementis tētis de rege in capite, &c. a writ directed to the justices of the Common-Pleas, to license them to admit of a fine for sale of lands holden in capite.

FINE non capiēdo pro pulchre placitādo, a writ to inhibit officers of courts to take fines for fair pleading.

FINE pro redisseſina capiēda, &c. a writ that lies for the release of one laid in prison for a release, upon a reasonable fine.

FINE for alienation, a reasonable fine paid the king by his tenants in chief, for licence to alienate their lands.

FINERS of Gold and Silver, are those who separate these metals from coarser ores. See the article **REFINERS**.

FINERY, in the iron-works, one of the forges at which the iron is hammered and fashioned into what they call a bloom, or square bar. See the article **Iron**.

FINE-STILLER, in the distillery, that branch of the art which is employed on the distilling the spirit from treacle or other preparations or recrements of sugar, is called fine-stilling, by way of distinction from malt-stilling; and the person who exercises this part of the trade is called a fine-stiller.

The operation in procuring the spirit from sugar is the same with that used in making the malt spirit; a wash of the saccharine matter being made with water from treacle, &c. and fermented with yeast. It is usual to add, in this case, however, a considerable quantity of malt, and sometimes powdered jalap, to the fermenting backs. The malt accelerates the fermentation, and makes the spirit come out the cheaper; and jalap prevents any musty head on the surface of the fermenting liquor, so as to leave a greater opportunity for the free access of the air, and thus to shorten the work, by turning the foamy into a hissing fermentation. *Shaw's Lect.*

FINGERS, in anatomy. See **HAND**.

FINING of Wines. See **WINE**.

FINISHING, in architecture, is frequently used for a crowning, acroter, &c. raised over a piece of building, to terminate, complete, or finish it. See the article **CROWNING**.

FINITE, something bounded or limited, in contradistinction to infinite. See the article **INFINITE**.

FINITOR, in astronomy, the same with horizon, so called because it terminates the sight or prospect. See **HORIZON**.

FINNIKIN, the English name of a species of

pigeon, remarkable for its wheeling round several times, whenever it courts the female.

FIRE, a general name, by which men seem to understand a certain sensation, or complex notion, of light, heat, burning, melting, &c.

The power of fire is so great, its effects so extensive, and the manner of its acting so wonderful, that some of the wisest nations of old, revered and worshipped it as the supreme deity. Some of the chemists also, after they had discovered its surprising operations, suspected it to be an uncreated being; and, indeed, the most famous of them have acknowledged it as the source of all their knowledge; and hence have professed themselves philosophers by fire, nor thought they could be honoured with a nobler title. Now, amongst all the wonderful properties of fire, there is none more extraordinary than this, that though it is the principal cause of almost all the sensible effects that continually fall under our observation, yet it is itself of so infinitely a subtle nature, that it eludes the most sagacious enquiries, nor ever comes within the cognizance of our senses; and hence others have been led to be of opinion, that it ought to be looked upon as spirit rather than body. Fire is generally divided into three kinds or species, viz. celestial, subterraneous, and culinary.

By celestial fire is principally understood that of the sun, without regard to that of the fixed stars, though this, perhaps, may be of the same nature.

By subterraneous fire we understand that which manifests itself in fiery eruptions of the earth, volcanoes, or burning mountains; or by any other effects it produces in mines, or the more central parts of the earth.

By culinary fire we mean that employed in all chemical operations, and the common occasions of life.

The sun's heat appears to be the actuating principle, or general instrument of all the operations in the animal, vegetable, atmospherical, marine, and mineral kingdoms.

Fire, considered in itself, seems to exist, in the greatest purity and perfection in the celestial regions; at least, we are insensible of any considerable smoke it yields: for the rays of light come to us from the sun, unmixed with any of that gross, feculent, or terrestrial matter, found in culinary and subterranean fires: but, allowing for this difference, the effects of the solar fire appear the same as those of culinary fire.

If we examine the effects of subterraneous fires, we shall find them the same with those produced by culinary fire. Thus burnt coals, cinders, and melted minerals, are thrown up by Vesuvius and other burning mountains. Warm nephritic exhalations, natural hot springs, steams, vapours, smoke, &c. are found in several parts of the globe, rising nearly in the same manner as if they were produced by the heat

heat of a furnace. Whence it appears, that subterraneous fires are of the same nature with the culinary.

All the physical knowledge we can have of a subject, must arise from attending to its properties and effects: but these properties and effects can never be discovered without the help of experiments; which, in philosophical enquiries, are the only interpreters betwixt the senses and the reason: whence all those notions of fire should be rejected as precarious and unsound, that are taken from the direct testimony of the senses, or the naked reason unassisted by experiments. In this enquiry, therefore, the mind should particularly be kept unprepossessed, and, before it pronounces, wait for full information. As men generally affix to the word fire, a complex idea of burning, light, heat, melting, &c. this idea should be analysed, in order to see what parts are essential, and what precarious or arbitrary.

We frequently find the effects of fire produced, where no visible fire appeared. Thus the fingers are easily burnt by an iron heated below the degree of ignition, or so as to be no ways visibly red-hot or fiery: whence it follows, that the eye is no judge of fire.

So likewise the touch gives us no positive notice of any degree of fire below the natural heat of the body, or any so great as to destroy the organ.

Again, the effects of fire are often produced without any manifest signs of burning, melting, &c. as in evaporations, &c. If this method of exclusion and rejection were pursued to its due length, we should, perhaps, find no criterion, infallible mark, or characteristic of fire in general, but that of a particular motion struggling among the minute parts of bodies; and tending to throw them off at the surface. If this should prove the case, then such a motion will be the form and essence of fire, and which, being present, makes fire also present; and, when absent, makes fire also absent: whence to produce, and produce this motion in bodies, will be one and the same thing. See *ELECTRICITY*.

The great and fundamental difference in respect to the nature of fire is, whether it be originally such, formed thus by the Creator himself at the beginning of things, or whether it be mechanically producible from other bodies, by inducing some alterations in the particles thereof. The former opinion is maintained by Homburg, Boerhaave, the younger Lemery, and s'Gravefande; the latter is chiefly supported by the English philosophers, lord Bacon, Mr. Boyle, and Sir Isaac Newton.

Bacon, in the treatise *De Forma Calicis*, deduces, from a great number of particulars, that heat in bodies is no other than motion, so and so circumstanced; so that, to produce heat in a body, nothing is required but to excite a certain motion in the parts thereof.

Boyle seconds him in an express treatise of the

mechanical organ of heat and cold, and maintains the same doctrine with new observations and experiments; as a specimen of which we shall here give the two following:

1. In the production of heat, says that able philosopher, there appears nothing on the part either of the agent or patient, but motion and its natural effects. When a smith briskly hammers a piece of iron, the metal thereby becomes exceedingly hot; yet there is nothing to make it so, except the forcible motion of the hammer impressing a vehement and variously determined agitation on the small parts of the iron, which, being a cold body before, grows, by that super-induced commotion of its small parts, hot: first, in a more loose acceptance of the word, with regard to some other bodies, compared with which it was cold before; then sensibly hot, because this agitation surpasses that of the points of our fingers; and in this instance oftentimes the hammer and anvil continue cold after the operation; which shews that the heat acquired by the iron was not communicated by either of those implements, as heat; but produced in it by a motion, great enough strongly to agitate the parts of so small a body as the piece of iron, without being able to have the like effect upon so much greater masses of metal as the hammer and the anvil: though, if the percussions were often and briskly renewed, and the hammer were small, this also might be heated: whence it is not necessary that a body itself be hot to give heat.

2. If a large nail be driven by a hammer into a plank of wood, it will receive several strokes on its head before it grows hot; but when it is once driven to the head, a few strokes suffice to give it a considerable heat; for while, at every blow of the hammer, the nail enters farther into the wood, the motion produced is chiefly progressive, and is of the whole nail tending one way; but when that motion ceases, the impulse given by the stroke being unable to drive the nail farther on, or break it, must be spent in making a various, vehement, and intestine commotion of the parts among themselves, wherein the nature of heat consists.

Agreeable to this, is the opinion of Sir Isaac Newton; who conceives, that gross bodies may be converted into light, by the agitation of their particles: and light, again, into gross bodies, by being fixed therein.

On the other hand, M. Homburg, in his *Essai du Souffre Principe*, holds, that the chemical principle, or element sulphur, which is supposed one of the simple, primary, pre-existent ingredients of all natural bodies, is real fire, and consequently that fire is coeval with bodies.

Dr. s'Gravefande goes on much the same principle: fire, according to him, enters the composition of all bodies, is contained in all bodies, and may be separated or procured from all bodies, by rubbing them against each other; and thus putting their fire

in motion: but fire, he adds, is by no means generated by such motion.

Mr. Lemery, the younger, agrees with these two authors in asserting this absolute and ingenerable nature of fire: but he extends it farther. Not contented to confine it as an element to bodies, he endeavours to shew, that it is equally diffused through all space, and that it is present in all places; in the void spaces between bodies, as well as in the insensible interstices between their parts.

This last sentiment falls in with that of Boerhaave, and the celebrated M. Musschenbroek. But notwithstanding what those able philosophers have advanced, it is evident that fire, heat, flame, &c. are only the different modifications of the particles of light, and that the particles of light themselves depend entirely on velocity for their lucific quality; since, by many experiments, we know, that the particles of bodies become lucid, or particles of light, by only producing in them a requisite degree of velocity: thus the particles in a rod of iron, being hammered very nimbly, shine and become red-hot; thus also the violent stroke of the flint against the steel, in striking fire, puts the particles of the steel, which it takes off, into such a motion as causes them to melt and become red-hot, which makes the sparks of fire produced by each stroke: as, therefore, fire consists in the great velocity of the particles, so it may be communicated from one body in which it is, to another in which it is not, after the same manner that one body in motion will communicate motion to another that has got none.

Fire differs from heat only in this, that heat is a motion in the particles of a body, with a lesser degree of velocity; and fire a motion with a greater degree of velocity, viz. such as is sufficient to make the particles shine; though we often call such a state as will burn, fire, though it does not actually shine; and we seldom call those lucid bodies fires, which only shine, and do not burn. These are a sort of phosphori, which, though they have no heat, yet seem to owe their lucidity to the motion of their parts. See the articles *HEAT* and *PHOSPHORUS*.

There seems to be no other difference between fire and flame, than this, that fire consists in a glowing degree of velocity in the parts of a body, while yet subsisting together in the mass; but flame is the same degree of velocity in the particles dissipated and flying off in vapour: or, to use Sir Isaac Newton's expression, flame is nothing else but a red-hot vapour. See the article *FLAME*.

FIRE, in chemistry, the great instrument by which most of the operations in that art are performed.

The kind, degree, direction, &c. of fire, are things the chemist is principally to attend to. There are, in chemistry, as many kinds of fire as there are mediums through which it may be conveyed, or

fuels that afford it. For common use, fire is conveyed through ashes, sand, water, &c. or directly through the containing vessel. Hence, fires are denominated of various kinds, as those of sand, filings of iron, and ashes, the reverberatory fire, the ignis rotæ, or fire for fusion, the lamp fire, the balneum marie, the vapour bath, and the fire of suppression. The chemists use also several other kinds of heats, which may be classed among the fires; such as insolation, a bath of horse-dung, a bath of the skins of grapes, and the heat of quick-lime.

For the balneum arenosum, or the fires or baths of sand, filings of iron, and ashes, balneum marie, balneum vaporis, or vapour-bath, see *BALNEUM*.

The reverberatory fire is made in a furnace covered with a dome, that by this means the heat or flame, which has always a tendency to make its escape at the superior parts of the furnace, may be reverberated, or beat back on the vessel immediately exposed to it. To expose a vessel to a naked fire, or to distil with a naked fire, is when there is no intermediate substance between the distilling vessel and the fire.

The ignis rotæ, or fire for fusion, is when a crucible or any other vessel containing the matter destined for fusion, is surrounded with live-coals.

Lamp fire is when any matter contained in a glass vessel is rendered hot by the equable heat of a lighted lamp.

Fire of suppression is when, in order to distil per descensum, the fire is laid above the matter, so that the moisture forced from it, by means of the heat, is precipitated to the bottom of the vessel; or when the body of the retort, or other vessel, is covered over with fire.

Insolation is when any matter designed either to be put into fermentation or dried, is exposed to the heat of the sun.

The bath of horse-dung, called also the horse's belly, is when a vessel, containing any matter to be either digested or distilled, is placed in a large heap of horse-dung.

Bath of the skins of grapes, like the bath of horse-dung, serves for digestions or distillations; the skins are to be collected after the vintage.

The heat of quick-lime moistened, may serve for some distillations.

Some differences may be found in the effects produced by these different fires, applied in the same degree: but they have not, perhaps, been noted as they deserve. In several bodies it is evident, that dry and moist heats have different effects, which we may find remarkably in the common culinary operations of boiling, roasting, baking, &c. and hence, when the same effects are required perfectly similar, the same kinds, as well as degrees, of fire are to be used.

The purest fire is that of alcohol, or perfectly pure spirit of wine; the next in purity is that of distilled

distilled oils; the next, that of charcoal, or charred turf; and the impurest, pit coal: but all these have nearly the same effect, when received through the same kind of medium.

Degrees of FIRE.—The last thing to be considered is, how to regulate and ascertain the degrees of fire in chemical operations, so as to produce the effects required in every case. The common directions of chemists about this matter are full of uncertainty; the first, second, third, and fourth degrees of heat, or fire, meaning no precise degrees, measured by any standard: however, according to Boerhaave, they are as follow:

The first degree of fire is that by which nature performs the office of vegetation in plants, and whereby chemistry imitates or does the like: this commences from the highest degree of cold, which, in Fahrenheit's thermometer, is denoted by one, and ends at eighty degrees; since in this whole interval we find certain plants give indications of life and growth. This heat is suited to extracting of the native spirits of odoriferous vegetables with oils, as that of roses, jessamin, &c. and again, to making the more curious insulations, &c.

The second degree of fire may be accounted that of the human body, in a healthy state. This degree is always greater than that of the ambient air, and may be supposed to commence at the 40th degree of the thermometer, and end about the 94th. Within this compass animals may live and subsist, that is, if their juices be of any degree of heat within these bounds. This degree is adapted to vinous and acetous fermentation, putrefaction, exclusion of the chick, the finer digestions, the making of tinctures and elixirs; and the adepts have used it for the first digestion of their mercury, by carrying the including vessel constantly in their pocket.

The third degree of fire is that which extends from 94 degrees of the thermometer to 212, at which last water usually boils. This degree is required in the distillation of simple and compound waters, the essential oils of vegetables, and will coagulate or consolidate the serum, blood, and other animal juices, and consequently destroy the creatures.

The fourth degree may be taken from 211 to 600 of the thermometer, within which latitude quick-silver or oil of vitriol boils, distils, or becomes volatile. This degree is suited to the melting of lead, tin, bismuth, &c. and the subliming of sal ammoniac and sulphur, the calcining of antimony, &c.

The fifth degree is that wherein the other metals melt, and which commences from 600 degrees of the thermometer, and ends where iron is held in a state of fusion. In this degree most bodies are destroyed; but glass, gold, silver, copper, and iron, remain long unchanged; all other fixed bodies grow red-hot in this degree, and all the unvitrifiable stones are calcined.

The sixth and highest degree of fire, hitherto known, is that of the burning lens, or concave, by M. Vilette, Tschirnhausen, Buffon, and others. The focus of these lenses will even volatilize what is called the metalline or mercurial part of gold, and vitrify the more terrestrial. See the article BURNING-GLASS.

The fires of sand, filings of iron, and ashes, have generally their degrees from the first to the third: the reverberatory fire has its degrees from the first to the fourth: the ignis rotæ serves for calcinations and fusions; and a vessel may receive different degrees of heat from a lighted lamp: the *balneum mariæ* and *balneum vaporis* have also their degrees: as has the fire of suppression its degrees: insolation has its degrees in proportion to the heat of the sun, to which the substances are exposed: the bath of horse-dung has its degrees according to the bulk of the heap, or the place in which it is lodged: the bath of grape-skins has also its degrees like that of the bath of horse-dung: and the heat of quick-lime has also its degrees; for according as we desire it more or less strong, we expose it to powder longer or shorter in the open air; and when we have occasion for all its heat, we use it as quick as we possibly can.

FIRE, in medicine. See CAUSTIC.

FIRE, in surgery. See CAUTERY.

St. Anthony's FIRE, in medicine. See the article ERYSIPELAS.

Walking FIRE, in meteorology. See WILL-WITH-A-WAISP.

FIRE, in theology. See the articles HELL, CONFLAGRATION, &c.

FIRE, in the art of war, a word of command to the soldiers, to discharge their musquets; to the cavalry, to discharge their carbines or pistols; to the grenadiers, to fire their grenades; and to the gunners, to fire the guns.

Running FIRE is when a rank of men, drawn up, fire one after another; or, when the lines of an army are drawn out to fire on account of a victory, each squadron or battalion takes it from another, from the right of the first line to the left, and from the left to the right of the second line.

FIRE-ARMS are all sorts of arms charged with powder and ball, as cannon, musquets, carbines, pistols, blunderbusses, &c. See the articles CANON, GUN, &c.

FIRE-ARROWS, certain destructive instruments used by privateers to set fire to the sails of the enemy: they are shot from a musketoon or swivel-gun; and being furnished with springs to prevent their going entirely through the sails, a match, being previously dipt in sulphur and nitre, is wound about the shaft of the arrow, which is iron, and this immediately catches fire, as soon after the explosion.

FIRE-BALL, in the art of war, a composition of meal-powder, sulphur, salt-petre, pitch, &c. about
the

the bigness of a hand-grenade, coated over with flax, and primed with a slow composition of a fusée. This is to be thrown into the enemy's works in the night-time, to discover where they are; or to fire houses, galleries, or blinds of the besiegers; but they are then armed with spikes or hooks of iron, that they may not roll off, but stick or hang where they are designed to have any effect.

FIRE-BARE, in our old customs, signifies a beacon, or tower, by the sea-side, wherein there were kept continual lights.

FIRE BOTE is fuel or firing for necessary use, allowed to tenants, out of the lands granted to them.

FIRE-ENGINE. See the article **ENGINE**.

FIRE-LOCK. See **GUN**, **MUSQUET**, &c.

FIRE-MASTER, in our train of artillery, an officer who gives the directions and proportions of ingredients for each composition required in fire-works, whether for the service of war, or for rejoicings and recreations.

His orders are given to the fire-workers and bombardiers, who must execute them.

FIRE-POTS, in the military art, small earthen pots, into which is put a charged grenade, and over that powder enough till the grenade is covered, then the pot is covered with a piece of parchment, and two pieces of match across, lighted: this pot being thrown where it is designed, it breaks and fires the powder, and burns all that is near it, and likewise fires the powder in the grenade, which ought to have no fuse, to the end its operations may be the quicker.

FIRE-SHIPS, in the marine, certain old ships attendant on a fleet, to destroy any of the enemy's ships.

They are provided with a train, which is constantly laid ready for execution, and runs round the ship's lower deck spirally from one end to the other; they have also grappling-irons at their yard-arms, to hook the enemy's rigging, &c. When they are firmly grappled, the boat is drawn up to the ship on the opposite side to the enemy, and fire is set to the train, the captain being the last man who leaves the ship on this occasion, which is a very dangerous enterprise. See that part of the article **SEA FIGHT**, which treats of the ancient marine war.

FIRE-WORKERS, officers subordinate to the fire-master.

FIRE-WORKS. See **PYROTECHNIA**.

Wild FIRE, a kind of artificial or factitious fire, which burns even under water, and that with greater violence than out of it. It is composed of sulphur, naphtha, pitch, gum, and bitumen; and is only extinguishable by vinegar mixed with sand and urine, or by covering it with raw hides. Its motion or tendency is said to be contrary to that of natural fire, and it always follows the direction in which it

is thrown, whether it be downwards, sideways, or otherwise.

Several are of opinion that the ancient Greeks and Romans used this fire in their engagements at sea: whether or not that was the case, it was applied against the Saracens in a sea-fight, commanded by Constantine Pogonates, in the Hellespont, and with such effect that he burnt the whole fleet therein, wherein were thirty thousand men.

Electrical FIRE. See **ELECTRICITY**.

FIRING-IRON, in farricry, an instrument not unlike the blade of a knife; which being made red-hot, is applied to a horse's hams, or other places standing in need of it, as in preternatural swellings, farcy knots, &c. in order to discuss them. Sometimes this is done for wenchers of the pasterns.

FIRKIN, an English measure of capacity, for things liquid, being the fourth part of the barrel: it contains eight gallons of ale, soap, or herrings; and nine gallons of beer. See **MEASURE** and **BARREL**.

FIRLOT, a dry measure used in Scotland. Th oat-firLOT contains $21\frac{1}{2}$ pints of that country; the wheat-firLOT contains about 2211 cubical inches; and the barley-firLOT 31 standard pints. Hence it appears that the Scotch wheat-firLOT exceeds the English bushel by 33 cubical inches. See the article **MEASURE**.

FIRMAMENT, in the old astronomy, the eighth sphere, or heaven, with regard to those of the seven planets which it surrounds. Besides the diurnal motion, according to Ptolemy, given it by the primum mobile, from east to west round the poles of the equator, it has an opposite motion to this, from west to east upon the poles of the ecliptic, called the secondary motion: by this the fixed stars advance, according to the order of the signs, about one degree in 70 or 72 years. More properly, the firmament is that space expanded above us in the heavens.

The word is Latin, *firmamentum*, and derived from *firmus*, sure, or steadfast.

FIRMAN is a passport or permit granted by the Great Mogul to foreign vessels, to trade within the territories of his jurisdiction.

FIRMNESS, *Firmitas*, denotes the consistence of a body, or that state wherein its sensible parts cohere in such a manner, that the motion of one part induces a motion of the rest.

FIRST-FRUILS, *Primitiæ*, among the Hebrews, were oblations of part of the fruit of the harvest, offered to God as an acknowledgment of his sovereign dominion.

FIRST-FRUILS, in the church of England, are the profits of every spiritual benefice for the first year, according to the valuation thereof in the king's books. See the article **ANNATES**.

FIR-TREE, *Abies*, in botany, a genus of evergreen trees, whose leaves are single, and for the most

most part produced on every side of the branches; the male flowers or catkins are placed at remote distances from the fruit on the same tree; the seeds are produced in cones, which are squamose.

The difference between these and the pines is, the latter having two or more leaves produced out of the sheath or cover.

These trees are all raised from seeds taken out of their polyspermous cones. The way to get out the seeds is, either by exposing the cones to a gentle fire, or by soaking them all night in water, which will cause their squamose cells to open, and readily emit their seeds. The former method is the best, provided they are not exposed to too great heat. But this ought not to be done until you are ready to sow them; which is best performed in the beginning of March.

These plants should be all raised in the nursery, where they may be protected from the birds; otherwise they will be in danger of being destroyed, when they first come up: for as they bring up the hulk of the seed on the top of the plant, the birds in picking off the hulk will break off the plant, whereby a whole bed may be lost in a few hours, if they are not carefully guarded from them.

The best time of sowing these seeds is about the latter end of March, or the beginning of April, on a bed of light earth, covering the seeds about half an inch deep with the same sort of earth. In this bed the plants should remain until the following spring, when there should be a number of beds prepared in the nursery to receive these seedling plants; and the beginning of April they should be transplanted into the beds, at the distance of six inches row from row, and at three inches asunder in the rows. If the season should prove dry, it will be proper to water the plants every week once or twice, according to the warmth of the weather; and the beds should be covered with mats, to screen the plants from the sun, and drying winds, until they have taken good root; after which time they will require no farther care, but to keep them clear from weeds. In these beds the plants may remain two years; at the end of which they should be transplanted into an open spot of ground; for their roots will in that time meet quite over the beds.

The distance which these plants should be placed in this nursery, should be four feet, row from row, and two feet asunder in the rows.

When the plants are planted, if the season should prove dry, they should be watered, to settle the earth to their roots; and if this is repeated three or four times, if the season should continue dry, it will greatly promote their taking new root, and secure them from the injuries of the drying winds. In this nursery the plants may remain two or three years, according to the growth they shall have made; and, during this time, the ground between the plants should be constantly kept clean from

weeds, and dug between the rows every spring; in doing of which, care must be taken not to cut or injure the roots of the plants: this is all the culture they will require during their continuance in the nursery: and, when they are transplanted into the places where they are to remain, the necessary care to be taken is, in taking them up, not to injure or cut off the roots, and let them be as little time out of the ground as possible; and, when they are out, to guard their roots from the drying winds. The surest time for removing of these trees is about the beginning of April; though they may, and often are removed with success at Michaelmas, yet the spring is the more sure season, especially in moist land.

Most of the kinds of firs may be removed at the height of six or seven feet; but those of two feet high are much better, and will in a years get the better of those taller trees. *Miller's Gard. Dict.*

FISC, *Fiscus*, in the civil law, the treasury of a prince.

FISCAL, in the civil law, something relating to the pecuniary interest of the prince or people.

FISH, in natural history, an animal which lives in the water, that being its natural element.

Willoughby, after Aristotle, has accurately distinguished fishes into *cetaceous*, *cartilaginous*, and *spinous*.

The *cetaceous*, called also *bellua marina*, have lungs, and breathe like quadrupeds: they copulate also like them, and conceive and bring forth their young alive, which they afterwards suckle with their milk.

The *cartilaginous* sort are those produced from eggs like large birds; which are also excluded the womb like those of birds.

The *spinous* kind are also oviparous; but their eggs are smaller, and they have spinæ up and down in their flesh to strengthen them.

The same author is likewise of opinion that it would be also proper to divide fishes into such as breathe with lungs, and such as breathe with gills; and then to subdivide those that breathe with gills into viviparous and oviparous.

Naturalists remark that the structure of fishes, and their confirmation to the element they reside in, is very wonderful. Their bodies are clothed and guarded in the best manner, with scales or shells, suitable to their respective circumstances, the danger they are exposed to, and the motion and business they are to perform. The center of gravity is placed in the properest part of the body for swimming; and their shape the best adapted to their making their way through the water, and most conformable to the rules of geometry. They have several parts peculiar to themselves; as fins to balance and keep them upright, and an air-bladder to enable them to rise and sink at pleasure. They have gills or branchiæ, whereby to respire, as animals do by their

lungs. The tail is the instrument of progressive motion, and serves to row them forward. Their eyes are peculiarly formed to enable them to correspond with all the conveniences and divergencies of rays, which the variations of the watery medium, and refractions thereof, may occasion; in which respect they bear a near resemblance to birds.

FISH, among seamen, a machine for drawing up the flooks of the anchor to the davit. See the article **DAVIT**.

It is composed of four parts, viz. the hook, the pendant, the block, and the tackle.

The pendant is a piece of strong rope passing through the block, hung over the end of the davit, which projects out from the forecable to keep the anchor at a distance from the ship's side, that the flooks may not tear it as they are drawn up: at one end of the pendant is fastened the hook, which is of sufficient strength and capacity to grapple the flooks under water, and sustain their weight: at the other end of the pendant is fixed the tackle, which is a complication of pulleys, to perform this operation.

FISHES of the Mast, certain pieces of wood hollowed on one side, and convex on the other, fastened securely on the masts of a ship to strengthen them, either when it is apprehended there is a necessity for this additional support to bear an extraordinary pressure of sail; or after they may have sustained some damage from a former occasion.

FISH-PONDS, those made for the breeding or feeding of fish.

FISHERY, a place where great numbers of fish are caught.

The principal fisheries for salmon, herring, mackerel, pilchards, &c. are along the coasts of England, Scotland, and Ireland; for cod, on the banks of Newfoundland; for whales, about Greenland; and for pearls, in the East and West Indies.

FISHERY denotes also the commerce of fish, more particularly the catching them for sale.

FISSURE, *Fissura*, a chap or crack, in surgery, is either natural or morbid: thus, the mouth, &c. is frequently called a natural fissure: morbid fissures are either those of the cranium or other bones, or chaps of the skin, which sometimes happen about the lips, anus, and other parts of the body.

The word is Latin, *fissura*, and derived from *findo*, to split or cleave.

FISSURE, in philosophy, is frequently applied to those divisions that are to be met with between layers of different kinds of earth or stone.

FISTULA, in surgery, a deep, narrow, and callous ulcer, generally arising from abscesses or ulcers.

The word is Latin, and literally signifies a pipe; this disorder being so called from its resemblance to a pipe or reed.

FISTULA in Anus, in surgery, an abscess running upon or into the intestinum rectum; though an abscess in this part, when once ruptured, does generally, if neglected, grow callous in its cavity and edges, and becomes, at last, what is properly called a fistula.

FISTULA LACHRYMALIS, a disease which attacks the great caruncle in the inward corner of the eye. See the article **EYE**.

FISTULAR, or **FISTULOUS**, appellations given by surgeons to wounds and ulcers, which degenerate into fistulas.

FISTULAR, among botanists, is applied to leaves and flowers that are tubular, or resemble a hollow pipe.

FIT, in medicine, denotes much the same with paroxysm. See **PAROXYSM**.

FITS of easy Reflection and Transmission, in optics. See the articles **REFLECTION** and **TRANSMISSION**.

FITCHEE, in heraldry, a term applied to a cross, when the lower end of it is sharpened into a point.

FITTING-OUT, in the sea-language, the act of providing a ship with a sufficient number of men to navigate her; also with provisions of all sorts, artillery, ammunition, masts, yards, sails, cordage, anchors, and other furniture: also the rigging and securing her masts against the dangers of the wind and sea.

FIXATION, in chemistry, the rendering any volatile substance fixed, so as not to fly off upon being exposed to a great heat; hence,

FIXED BODIES are those which bear a considerable degree of heat without evaporating, or losing any of their weight.

FLACCIDITY, among physicians, a disorder of the solids, cured by astringent and cardiac medicines, joined with exercise and good air.

FLAG, in the sea language, the banners or colours by which an admiral is distinguished at sea.

FLAGS in the British Navy, are either red, white, or blue; and they are hoisted either at the heads of the main-mast, fore-mast, or mizen-mast.

Flags, when displayed from the top of the main-mast, are the distinguishing marks of admirals; when from the fore-mast of vice-admirals; and when from the mizen-mast, of rear-admirals.

The highest flag in the British navy is the anchor and rope, which is only displayed when the lord-high admiral, or lords commissioners of the admiralty are on board; the next is the union, the distinction peculiar to the second officer, called admiral of the fleet; and the lowest flag is the blue at the mizen-mast.

FLAGELLANTES, **WHIPPERS**, in church history, certain enthusiasts in the thirteenth century, who maintained that there was no remission of sins without flagellation, or whipping. Accordingly

ingly they walked in procession, preceded by priests carrying the cross, and publicly lashed themselves, till the blood dropped from their naked backs.

FLAGEOLET, or **FLAJEOLET**, a little flute, used chiefly by shepherds and country people. It is made of box, or other hard wood, and sometimes of ivory, and has six holes besides that at the bottom, the mouth-piece, and that behind the neck. See **FLUTE**.

FLAIL, an instrument for threshing corn. See **CORN** and **THRESHING**.

FLAKE, among gardeners, a kind of striped carnations, with only two colours.

FLAMBEAU, a kind of large taper, made of hempen wicks, by pouring melted wax on their top, and letting it run down to the bottom. This done, they lay them to dry; after which they roll them on a table, and join four of them together by means of red-hot iron; and then pour on more wax, till the flambeau is brought to the size required.

FLAME, *Flamma*, in physiology, the small parts of an inflammable or considerably unctuous body, that are set on fire, or briskly agitated and thrown off, with a certain vibrative motion at the surface of that body into the open air: or, in Sir Isaac Newton's words, the flame of a body is only the smoke thereof heated red-hot; and the smoke is only the volatile part of the body separated by the fire. See **FIRE** and **SMOKE**.

FLAMEN, in Roman antiquity, the name of an order of priests, instituted by Romulus or Numa; authors not being agreed on this head.

FLANCH, **FLANQUE**, or **FLASQUE**, in heraldry, an ordinary always borne double, being the segment of a circular superficies.

FLANNEL, or **FLANEL**, a loose sort of woollen stuff not crossed, and wove on a loom with two treddles, like bays.

FLANK, in the menage, the side of a horse between the ribs and haunches.

FLANKS of an Army, are the troops encamped on the right and left, as the flanks of a battalion are the files on the right and left.

FLANK of a Bastion, in fortification, that part which joins the face to the curtain. See the article **BASTION**.

Oblique FLANK, or **Second FLANK**, that part of the curtain from whence the face of the opposite bastion may be discovered.

Retired FLANK, or **Low FLANK**, or **Covered FLANK**, one of the platforms of the cazemate. See the article **CAZEMATE**.

These retired flanks are a great defence to the opposite bastion, and the passage of the moat, because the besiegers cannot see nor easily dismount their guns. The curtain is esteemed the strongest part of the fortification, because flanked at both

ends; and the face is accounted the weakest, as having only one defence from the opposite flank.

FLANKED ANGLE, in fortification, that formed by the two faces of a bastion.

FLANKING ANGLE, or *Angle of the TENAILLE*, that composed of the two lines of defence, and pointing towards the curtain. See the article **TENAILLE**.

FLANKING Line of Defence. See the article **LINE of Defence**.

FLATS, in music, a kind of additional notes, which, together with sharps, serve to remedy the defects of musical instruments, wherein temperament is required. See **TEMPERAMENT** and **SHARP**.

FLATULENCY, in medicine, a disorder of the bowels arising from a weak stomach, and crude flatulent aliment, as pease, beans, lentils, coleworts, hard fat flesh, &c. which degenerate into wind, creating great anxiety if not evacuated, and difficulty of breathing.

Another cause of flatulencies are congestions of blood in the branches of the vena porta; whence proceed anxieties of the præcordia, difficult breathing, cholic pains, heart-burn, head-achs, vertigo, and watchfulness.

If the flatulency arises from crudities in the stomach, evacuations are first of all necessary; after which may be given bitters, aromatics, carminatives, and strengtheners, with a spare diet and exercise. If it proceeds from congestions of blood, as is the case of hypochondriacs, a vein must be opened; and if the body is costive, an emollient clyster or a gentle laxative will be proper. If these fail, chalybeate medicines are to be called in, as tincture of vitriol of iron, steel-filings finely powdered, from six to ten grains, or oil of cinnamon with sugar or bitters, spaw-waters, and constant exercise.

FLAX, *Linum*, in botany, a plant from which linen is manufactured.

There are several species of this plant, which are preserved in some curious gardens of plants for variety sake; but, as they are of little use or beauty, it would be needless to expatiate on them in this place.

The *linum sativum*, or manured flax, is that which is cultivated for use in divers parts of Europe, and is reckoned an excellent commodity: the right tilling and ordering of which is esteemed a good piece of husbandry.

This should be cultivated upon a rich soil that has not been ploughed for several years, upon which flax always makes the best improvement: but, as it draws greatly from the soil, it should not be sown two years together upon the same ground. The land must be well ploughed, laid flat and even, upon which the seeds should be sown about the middle

middle of March, when the weather is mild and warm. During the spring, you must carefully weed it; which if neglected, especially in a moist season, the weeds will over-grow and destroy the crop. There are some persons who recommend the feeding of sheep with flax, when it is a good height; and say, they will eat away the grass and weeds, and do the flax good; and if they should lie in it, and beat it down, or flatten it, the next rain that falls it will rise again: but this must not be practised but in a moist season, and upon a rich soil; for if the ground be poor, or the spring dry, it will not rise again to any considerable height.

The best seed is that which comes from the East country, and is known by the name of Riga flax; for if the English seed be sown three or four times, it is very apt to degenerate. If the seed be good, two bushels will be enough to sow an acre; but if it be but middling, there should be a greater allowance.

Towards the latter end of August the flax will begin to ripen, when you must be careful that it grow not over ripe; therefore you must pull it up as soon as the heads begin to change brown, and hang downwards, otherwise the seeds will soon scatter, and be lost; so that the pluckers must be nimble, and tie it up in handfuls, setting them upright till they be perfectly dry, and then house them. If the flax be pulled when it first begins to flower, it will be whiter and stronger than if it stand till the seed is ripe; but then the seed will be lost.

This is a plant of the greatest use in several of the most essential parts of life: from the seeds an expressed oil is drawn, which is of great use in medicine, painting, &c. from the bark of the stalks is made linen, and from the rags of linen is made paper: so that this plant may be esteemed as one of the most valuable and necessary in many of the principal conveniences of life. *Miller's Gard. Dict.*

This plant has a more oily taste than mallow, and is the chief of the emollient tribe. The seeds afford an excellent medicine, since from them is expressed an oil, which is anodyne, demulcent, and extremely adapted to all manner of aperities; it relaxes, and dissolves acridities, whence it is of extraordinary service in the most desperate cholics. The stiff and rigid limbs, being anointed with this oil, are relaxed and rendered flexible. This oil, when fresh drawn, and taken at the mouth, is very good in a pleurisy, and a cough, to help expectoration; and, injected in clysters, is very proper in the hæmorrhoids, and indurated fæces, whence proceeds the cholic; mixed with sealed and japan earth, it is a great arcanum in the dysentery: an emulsion of the seeds is of service in the pleurisy and peripneumony; the oil is a very good remedy against the stone: the seeds reduced to a meal, and boiled and prepared in the form of a cataplasin, are

applied to tumours and abscesses, in order to mollify and ripen them. The seed, boiled in water, makes a mild oily decoction, prescribed to be drank as an anodyne in inflammations of the small intestines, the diarrhoea, the dysentery, nephritic pains, and retention of urine. The oil, boiled with honey, clears the face and skin of spots, and all cutaneous blemishes. The leaves are emollient, and the smell of the flowers is not poisonous, as some authors have written. To close all, we should observe, that whereas cotton can never be used about wounds, on account of its denticulated parts, which dispose to inflammations; linen, the manufactured produce of this plant, is, by its extraordinary softness, smoothness, and flexibility, of all other things, the best adapted to such purposes. *Hist. Plant. script. Boerhaave.*

As it is agreed that the lightest loams and the thickest crop afford the finest flax, it may be of use to let the farmer know how he may save such crops from lodging, as they generally do. The method is a little expensive; but if it answers, it will quit cost very well. When the flax is in the ground, divide your field into equal squares, the sides of which may be four or five feet long; and at each angle thrust a forked stick steady in the ground. When your flax is some inches high, lay from stick to stick a light cross pole; and this will support the flax, and hinder it from lodging. Some use ropes instead of poles; but they yield too much, and answer but imperfectly.

High winds are so common in this country, that there is reason to apprehend, that the Dutch method of laying flax loose upon the ground would be attended with considerable inconvenience. The following method is much safer: tie gently each handful as close as may be to the heads; and then, spreading out the ends, set it upright on the ground. Three or four of these, together, make one stook; and into such small stooks divide all the flax you have. They soon dry, because the wind has free access to the stalks, as the sun has to the heads, and the rain cannot lodge in any quantity upon them.

Rippling comes next. Two men may work at every instrument, by fixing it on a bench, that one may sit at either end. Let them take small handfuls at a time, and draw the flax through the ripple without violence. Two women to each bench are necessary to hand the flax in bundles to the rippers, to receive it from them again, to sort it according to their several degrees of length, strength, ripeness, and fineness, and to tie it loosely in little sheaves.

After rippling, the seed must be carried to the granary, and the flax laid down to water. If possible, dispose of the whole into your ponds together. The summer, which draws hastily towards an end, is your fittest season, and should be huf-banded

banded with care: however, let nothing tempt you to use bog-holes and running waters. It is better to delay to the next season, than to discolour or damage all your flax.

Cover your flax, to keep it down, with your slutch or mire at the bottom of your ponds, or, till that be gathered in sufficient quantities, with clay, rushes, fern, or timber. From four to twelve or thirteen days is the time requisite for watering. After the fourth, examine your flax daily, and be particularly careful not to let it lie too long. It is a mistake, on the safer side, to draw it off the soonest.

In grafting, the shortest grafts should be preferred. Dry sand-banks do well. On either the flax must be turned every second day, and generally lies from a fortnight to three weeks.

To dry your flax, heat your oven thoroughly; then let it cool, till a man can stand in it without uneasiness; fill it over night, and your flax will be ready for the break next morning. The dirt and straws scutched out of the flax in one day, will heat the oven for the next.

When you break your flax, take sheaf by sheaf out of the oven, as you use it: it comes crisp under the engine, works the better and more easily. It is an error to lay the flax, as we do, as far as may be from the joint. The nearer it is placed to the center of motion in the break, the more easily it splits, and the less damage it receives.

In scutching, chuse the broad round scutch: the square and narrow one, in use among us, cuts and destroys the flax.

By the time the flax is scutched, and about the middle of October, it will be time to thresh the seed.

This may be done by driving horses backwards and forwards on the bows, or by drawing over them a heavy rolling-stone upon a smooth hard floor.

Cleaning it requires more nicety. To do it thoroughly, it must first go through the winnow, which separates it from the bows; through the riddle next, to take out straws, stones, and larger dirt; then successively through two different sieves; the first bored with oval holes, to let through the seed, and nothing else of greater bulk; the second closer, to retain the seed, and afford a passage to all smaller bodies; and lastly, through the screen or wire-harp, which frees it from all dust.

When the flax-dresser has thus cleaned his seed, he should return to his flax, and put it through the fining-mills. The wheel in these turns alternately from right to left, and from left to right, twice each way; and, according to the number of these double turns, the flax comes out the finer, the smoother, and the softer. Fourcore such turns is the most that any flax requires; and probably as much as it will bear.

N. B. For want of these fining-mills in Scotland beating of flax is directed.

In hackling, women and children should be employed from choice. They work with greater gentleness than men; and care and tenderness are the main excellencies in this business. For the best flax, four sets of hackles will be requisite, each of them of a different fineness: through these it may be drawn successively, and every time with proportionable caution. The last, whose teeth are like the finest needles, requires the utmost skill, and should be trusted with few hands.

FLEA, *Pulex*, in zoology, a genus of insects without wings, of a roundish, compressed figure: the legs are three pair, and formed for leaping; the eyes are two, and simple; the mouth is bent downwards; the colour is a deep purple, approaching to black.

FLEA-BITTEN, that colour of a horse, which is white or grey, spotted all over with dark reddish spots. See HORSE.

FLEAM, in surgery and farriery, an instrument for letting a man or horse blood.

FLEECE, the covering of wool, shorn off the bodies of sheep. See WOOL.

Order of the Golden FLEECE, an order of knighthood instituted by Philip II. duke of Burgundy. These knights were at first twenty-four, besides the duke himself, who reserved the nomination of six more; but Charles V. increased them to fifty. He gave the guardianship of this order to his son Philip, king of Spain; since which, the Spanish monarchs are chiefs of this order. The knights had three different mantles ordained them; at the grand solemnity, the collar and fleece.

FLEET, in naval affairs, a company of ships of war, or merchantmen, or both, bound on any particular expedition or voyage.

As the security, wealth, and glory of these kingdoms principally depend on the resolution and skill with which our fleets are conducted, it may be thought necessary to give our readers, who are unacquainted with this subject, a clearer idea of the operations of fleets and squadrons, than they may have formed before; this we more cheerfully attempt, as it seems to have been wholly neglected hitherto in works of this kind.

The principal article to be considered in a fleet at sea is order, by which is meant the different methods of ranging or drawing it up in several lines and forms for which it may be designed: in which, two things are to be considered; first, the position of each ship with regard to the wind; second, the position of each ship with respect to the fleet. We cannot make any alteration in either of the circumstances without changing the whole position of the line, which will otherwise remain complete. See the article LINE.

When a fleet engages, it ought to be drawn up

in a different form from that in which it fails. A fleet that fails in fight of an enemy must alter its position from that it would maintain, were there none in view, or none to be expected. When a fleet fails before the wind, it has likewise its particular form of failing, as it has also when it chafes an enemy, makes a retreat, guards a streight or passage, or is obliged to force through one; or whether at anchor in a road or harbour, or going into either, to insult or attack an enemy. In this variety of circumstances, proper regard must be had to the most advantageous position or form the fleet can be ranged in, before it enters upon action.

There are three things to be considered before we can judge of the good form or disposition of a fleet.

1. If that form puts it into the best disposition of executing the admiral's design; such as the most expeditious, as well as most commodious, order of sailing on any enterprize, &c. or if, when obliged to retreat, such arrangement secures it best from the attacks or pursuits of an enemy. 2. If that order closes the fleet more or less; because the closer the ships are, they are the less liable to be separated; the several commanders can better aid and assist each other upon any occasion, and have the easier communication with their respective admirals and commanding officers. 3. If from this order the line of battle may be easiest formed; because all orders must tend principally to that, as the only one to engage to advantage. See EVOLUTION.

In a naval engagement, as we shall fully explain in that article, the ships are drawn up in a line of battle in two columns parallel to each other, close upon a wind. CLOSE-HAULED.

There are several advantages which result from being to windward, as 1. the fleet to windward can edge down on the enemy, when and as near as shall be judged convenient; consequently regulates the time and distance most advantageous to come to action; 2. if the fleet to windward is more in number, it may easily detach some ships to send after the rear of the enemy, which must undoubtedly throw them into confusion; 3. if any of the ships of the fleet to leeward should be disabled, whether in the van or rear, or even in the center, the fleet to windward may with the greater ease send down their fire-ships upon them, or send a detachment after any part of the flying enemy: 4. we must also attribute, amidst other advantages of being to windward, that of being sooner freed from the inconvenience of the smoke of the enemy, as well as of our own; for the wind repelling the smoke of the cannon back again into the ship, so greatly incommodes those who are quartered at the guns as to deprive them totally for some time of the sight of the enemy.

On the other hand, the advantages of being to leeward are likewise considerable, inasmuch that

there are who maintain they are at least equal to those of being to windward; but if all circumstances are duly considered, they will certainly find the advantages of being to windward the greatest a fleet can possibly have, whether superior or inferior to the enemy; though we must allow, that, on some occasions, as when the wind blows hard, it may be more advisable to get to leeward, if we can, especially if the sea runs so high that the weather, or windward fleet, cannot open its lowest tier, when obliged to engage a great number of ships, or in an action between two single ships.

1. The fleet to leeward fire to windward, and consequently the ships may make use of their lower tier of guns, without being under apprehension that any sudden squall of wind should over-power them by the water rushing in irresistibly between decks; an advantage which the English fleet, under Sir Edward Hawke, had in some measure over the French fleet, commanded by M. Conflans, in that memorable action off Belleisle, Nov. 20, 1759, where they fatally experienced our superior skill, resolution, and seamanship. This circumstance is certainly the greatest advantage a fleet to leeward can have; for it is difficult to conceive the confusion and terror which sudden gusts of wind occasion amongst the men between decks, when the waves pour in and lay the ship on her broadside, so as often to endanger her overturning, or sinking before the ports can be secured.

2. The fleet to leeward may easier cover any of their ships which are disabled in action, which the fleet to windward cannot effect without great difficulty, and even the risk of being destroyed in the attempt.

3. The fleet to leeward may more easily make a retreat if defeated, whereas the fleet to windward cannot so well escape, without being reduced to the necessity of forcing its way through the enemy's line, which must be attended with the most fatal consequences.

When a fleet is obliged to retreat in sight of an enemy, the best way to secure its retreat will be by sailing in a sort of half-moon, the admiral being in the center, the fleet divided and ranged in order, one half on the starboard, and the other half stretching out on the larboard side, and keeping the fire-ships, transports, &c. in the middle. This manner of ranging a fleet seems the most advisable, because the enemy can never approach those who endeavour to escape, without exposing themselves at the same time to the fire of the ships to windward. If the admiral thinks this form gives too great an extent to his fleet, he may easily close his wings or quarters, and make the half-moon more complete, in the midst of which he may place his convoy in safety.

The most natural course, however, in this form

of failing, is to steer away before the wind: but if necessary, the ships may bear away large on either tack, or even may keep close upon a wind.

In chasing a fleet that endeavours to escape, the best cruisers are detached after them, in order to pick up the stragglers or force them to action: the body of the victorious fleet should keep the same order or line with the enemy, as high as possible, to be ready for action if necessary. This, however, is only to be understood when the fleet that is chased may not be so inferior to the other, but that it may hazard an action; for if the one bears no proportion to the other, they must bear down upon them in the same manner as a conquering army affore carries all before it when it has forced an enemy's camp: otherwise, were the conquerors to wait drawing up in form, the enemy would undoubtedly take the advantage of such an opportunity to make their escape.

In order to protect the entrance of a freight or passage in the most effectual manner, there should be a fleet nearly double in number to that which would force its way through; there must then be two divisions made, the one to keep one side while the other is ranged along the other, that when the enemy present themselves at the entrance, the weather-moost squadron may crowd all the sail it can before the wind upon them, at the same time that the leeward squadron keeps its wind to intercept them: so that in this manner it will be impossible for the enemy to escape by any manœuvre it may attempt. The essential point of a commanding officer who attempts to force a passage, is to avail himself of the reigning winds which may best favour his designs, and possibly it would be most expedient to range his squadron in the form of a retreat, by closing the wings or quarters a little, to give them the less extent; in this the squadron can never be attacked without being able to defend itself from all quarters to greater advantage than in the former position.

When a fleet comes to an anchor, there are five circumstances to be considered: 1. that the ground be good and holding; 2. that the place be well sheltered against the reigning winds which blow on that coast; 3. that the ships may easily get under sail with the same wind that may serve an enemy, and at the same time be able to dispute the advantage of the wind with them; 4. that they may readily form the line as soon as they get under sail; 5. that the ships may have room to keep clear of each other in getting under way, in order to which they should be regularly anchored in one or many lines, about three cables length asunder, and one hundred and twenty fathoms between each ship.

When a fleet is under a necessity of continuing at sea in bad weather, it should form itself into three columns, leaving a great interval between each ship, without at the same time widening the distance between the columns; so that it may be in this man-

ner less liable to be separated, and the ships in less danger of falling aboard each other.

If the ships have a good offing and sea room enough to drive, they will lie to under their courses; which will subject them to labour less, and not strain so much on their masts, rigging, &c. but if they should not have drift enough, they must lie to under their main-sails, or mizens only, which will still keep them much easier than if they were under no sail at all.

Lastly, if a fleet designs to force into an harbour, wind, weather, &c. permitting, some ships should be ordered to divert the out-forts, by coming to an anchor and placing themselves in such a manner as to bring their broadsides to bear upon them: when that is accomplished, the brisk and continued fire of a ship will greatly distress the enemy; but more especially against stone-works, which fly about and do great execution, whilst the main body of the fleet pushes into harbour.

FLEETING, among sailors, changing the situation of a tackle, when the blocks or pulleys are drawn together: the use of fleetings is to separate the powers which produce any great effort, that the force may be increased, which is destroyed by their meeting.

FLEMISH, or the **FLEMISH-TONGUE**, is that which we otherwise call Low-Dutch, to distinguish it from the German, of which it is a corruption, and a kind of dialect. See **GERMAN**.

It differs from the Walloon, which is a corruption of the French language. The Flemish is used through all the provinces of the Netherlands.

FLEMISH BRICKS, a neat, strong, yellow kind of bricks, brought from Flanders, and commonly used in paving yards, stables, &c. being preferable for such purposes to the common bricks. See **BRICK**.

FLESH, *Caro*, in anatomy, a similar-fibrous part of an animal body, soft and bloody, being that of which most of the other parts are composed, and whereby they are connected together; or more properly, it is such parts of the body where the blood-vessels are so small, as only to retain blood enough to preserve their colour red.

FLESH, among botanists, is all the substance of any fruit that is between the outer rind and the stone; or that part of any root that is fit to be eaten.

FLESH-COLOUR. See **CARNATION**.

FLEUR DE LISEE, in heraldry, the same with *flory*. See the article **FLORY**.

FLEXIBLE, in physics, a term applied to bodies capable of being bent or diverted from their natural figure or direction.

FLEXION, in anatomy, is applied to the motion by which the arm or any other member of the body is bent. It is also applied to the muscles, nerves, &c.

FLEXOR, in anatomy, a name applied to several muscles, which are so called from their office, which is to bend the part to which they belong, in opposition to the extensors, which open or stretch them.

FLINT, *Silex*, in natural history, a semi-pellucid stone, composed of crystal defaced with earth, of one uniform substance, and free from veins; but of different degrees of colour, according to the quantity of earth it contains, and naturally surrounded with a whitish crust.

Oil of FLINTS, a name given to the liquor obtained from a mixture of four ounces of calcined and powdered flints, with twelve ounces of salt of tartar; this being melted together in a strong fire, runs into glass, which is to be powdered and set in a cellar, where it runs into an oil per deliquium.

FLOAT of a Fishing-Line, the cork or quill that floats or swims above water.

Float also signifies a certain quantity of timber bound together with rafters, athwart, and put into a river to be conveyed down the stream; and even sometimes to carry burdens down a river.

Float-Boards, those boards fixed to water-wheels of under-shot mills, serving to receive the impulse of the stream; whereby the wheel is carried round. See the articles **WHEEL** and **MILL**.

Floatages, all things floating on the top of the sea or any water; a word much used in the commissions of water-bailiffs.

FLOATINGS, in husbandry, the drowning or watering of meadows.

FLOATING of Cheese, among housewives, separating the whey from the curd. See **CHEESE**.

FLOOD, a deluge or inundation of waters. See the article **DELUGE**.

FLOOKING, among miners, a term used to express a peculiarity in the load of a mine. The load or quantity of ore is frequently intercepted in its course by the crossing of a vein of earth or stone, or some different metallic substance; as in which case the load is moved to one side, and this transient part of the land is called a flooking.

FLOOR, in architecture, the under side of a room, or that part we walk on.

Floor, in ship-building, the bottom of a ship, or all that part on each side of the keel, which approaches nearer to an horizontal than a perpendicular situation; whence it is common to say, a sharp floor, a flat floor, a long floor, &c. whence,

Floor-Timbers, are those which are placed immediately across the keel, upon which the bottom of the ship is framed, and the upper parts of the timbers are constructed. See **TIMBER**.

FLORAL, in general, something belonging to a flower. See **FLOWER**.

Thus floral leaves are those found only near flowers.

FLORAL GAMES, in Roman antiquity, annual

games instituted in honour of the goddess Flora, which began to be celebrated on the fourth of the calends of May, or the twenty-eighth of April, and were continued to the calends, of first of May.

FLORID STYLE is that too much enriched with figures and flowers of rhetoric.

FLORILEGE, *Florilegium*, a name the Latins have given to what the Greeks call *ανθολογιον*, anthology. See the article **ANTHOLOGION**.

FLORIN is sometimes used for a coin, and sometimes for a money of account.

Florin, as a coin, is of different values, according to the different metals and different countries where it is struck. The gold florins are most of them of a very coarse alloy, some of them not exceeding thirteen or fourteen carats, and none of them seventeen and a half. As to silver florins, those of Holland are worth about 1*s*. 8*d*. those of Genoa were worth 8*d*. sterling.

Florin, as a money of account, is used by the Italian, Dutch, and German merchants and bankers, but admits of different divisions at different places: in Holland it is on the footing of the coin of that name, containing twenty stivers. At Franckfort and Nuremberg it is equivalent to 3*s*. sterling, and is divided into creutzers and pfennings; at Liege it is equivalent to 2*s*. 3*d*. at Strasbourg, to 1*s*. 8*d*. in Savoy, to 11*d*. at Genoa, to 8½*d*. and at Geneva, to 6½*d*. See the article **COIN**.

FLORINIANS, *Floriniani*, in church history, a sect of heretics, of the second century, so denominated from their leader Florinus, who made God the author of evil.

They are a species of the gnostics, but deny the judgment and resurrection, and hold that our Saviour was not born of a virgin. They were also called borborites. See the article **BORBORITES**.

FLORIST, *Florista*, according to Linnæus, is an author, or botanist, who writes a treatise called Flora, comprehending only the plants and trees to be found growing naturally in any place. However, in the more common acceptation of the word, florist signifies a person well skilled in flowers, their kinds and cultivation. See the article **FLOWER**.

FLORY, **FLOWRY**, or **FLEURY**, in heraldry, a cross that has the flowers at the end circumflex and turning down, differing from the potence, inasmuch as the latter stretches out more like that which is called patee. See the article **POTENCE** and **PATEE**.

FLOS, or **FLOWER**, in botany. See the article **FLOWER**.

FLOS, in chemistry, the most subtile part of bodies separated from the gross parts by sublimation, in a dry form.

FLOSCULOUS, among botanists, an appellation given to compound flowers made up of a number of lesser ones, all inclosed in the same common cup.

The plants with floscul flowers make one of Tournefort's classes, called by Linnaeus *syngenesia*. See the articles *BOTANY* and *SYNGENESIA*.

FLOUR, the meal of wheat-corn, finely ground and sifted. See *MEAL*.

FLOWER, *Flor*, among botanists and gardeners, the most beautiful part of trees and plants, containing the organs or parts of fructification. See the article *FRUCTIFICATION*.

The parts of a flower are the ovary or pistil, the corolla or flower-petals, the stamina or chives, the empalement or calyx, the perianthium, pericarpium, and fruit. See the articles *PISTIL*, *COROLLA*, *STAMINA*, &c.

According to the number of petals, or flower-leaves, flowers are called monopetalous or one-leaved, dipetalous or two-leaved, tripetalous or three-leaved, &c. Flowers are again distinguished into male, female, and hermaphrodite: the male flowers are those containing stamina, without any pistil or fruit, commonly called staminate flowers. The female flowers are such as contain the pistil, which is succeeded with fruit; these are called fruitful or knitting flowers. The hermaphrodites are those which contain the organs of both sexes, viz. stamina and pistils; and these are by far the most numerous.

From the different figures and disposition of the flower-leaves of plants, Mr. Tournefort has established a system of botany; whereas that of Linnaeus is chiefly founded on the number and disposition of the stamina. See *BOTANY*.

Flowers were in great request among the ancients: they adorned their temples, houses, and even tombs with them; but their principal use seems to have been at entertainments, where the guests were always decked with flowers, and even the room strewed with them.

Quincy tells us, that flowers, designed for medicinal use, should be plucked when they are moderately blown, and on a clear day before noon: and that for conserves, roses must be taken in the bud.

For the method of preserving specimens of flowers, see the article *HORTUS SICCUS*.

Eternal FLOWER, the English name of the xeranthemum. See *XERANTHEMUM*.

Everlasting FLOWER, the English name of the gnaphalium. See *GNAPHALIUM*.

FLOWER-FENCE, the English name of the poinciana. See *POINCIANA*.

FLOWER-DE-LUCE, the same with the iris. See *IRIS*.

Sultan-FLOWER, the same with the cyanus. See *CYANUS*.

Sun-FLOWER, the English name of the helianthus. See *HELIANTHUS*.

Trumpet FLOWER, the same with the bignonia. See *BIGNONIA*.

Wind-FLOWER, the same with the anemone. See *ANEMONE*.

FLOWERS, in chemistry. See the article *FLOS*.

FLOWER-DE-LIS, or **FLOWER-DE-LUCE**, in heraldry, a bearing representing the lily, called the queen of flowers, and the true hieroglyphic of royal majesty; but of late it is become more common, being borne in some coats one, in others three, in others five, and in some semee, or spread all over the escutcheon in great numbers.

The arms of France are, three flowers de lis or, in a field azure.

FLOWING SHEET, in the sea-language; the sheets are ropes fastened to the lower corners of the sails, and they are said to be flowing when the wind is fair or large, as it is termed by seamen, as the sheets are at this time not drawn so tight as when the ships are close hauled.

A ship is said to have a flowing sheet when the wind crosses the line of her course at right-angles, that is to say, a ship steering north, with the wind at east, has a flowing sheet; for if she were close-hauled, she would steer two points nearer the wind, viz. N. N. E. See the article *CLOSE-HAULED*.

FLOX, among dyers, signifies well cleaned wool, used to absorb the colours of cochineal.

FLUENT, in fluxions, the flowing quantity, or that which is continually either increasing or decreasing, whether line, surface, solid, &c. See *FLUXION*.

It is easy to find the fluxions, where the fluents are given; but, on the contrary, it is very difficult to find the fluents of given fluxions.

FLUID, in physiology, an appellation given to all bodies, whose particles easily yield to the least partial pressure, or force impressed.

Some philosophers make the following distinction in fluids; those which flow or spread themselves till their surfaces become level or horizontal, they call liquid; in contradistinction to flame, smoke, vapour, &c. which are also fluids, but do not acquire such a surface. Those which are capable of exciting in us the idea of moistness, as water, &c. they call humid, distinguishing them thereby from air, quicksilver, and melted metals. But these distinctions are quite unnecessary in a philosophical sense; the surfaces of all fluids being level, or horizontal, when not prevented by the bodies about them: and humidity is only a relative quality; for though quicksilver will not moisten or stick to a man's finger, it will to silver or gold. See *FLAME*, *SMOKE*, *LIQUID*, &c.

FLUOR, in physics, a fluid, or more properly, the state of a body that was before hard or solid, but is now reduced by fusion, or fire, into a state of fluidity.

FLUOR, in mineralogy, implies a sort of mineral concretion, frequently found amongst ores and stones, in mines and quarries.

FLUOR ALEUS, or WHITES, in medicine, is a discharge of whitish gleety matter by the natural parts of the fair sex. This humour issues sometimes from the vessels of the uterus, and sometimes from the glands of the vagina. In the former case the discharge is suppressed during the time of the menstrual courses; in the latter, it subsists with them, and continues even in the time of pregnancy.

In both species of the disease the principal intention ought to be directed towards mending the habit of body, from some fault in which they derive their origin: but when the seat of the distemper is in the vagina, it will, however, require topical applications.

Wherefore, generally speaking, it will be proper to begin the cure by giving a vomit, especially with ipecacuanha wine; frequent purging is indicated, chiefly with rhubarb; which may be taken either in substance, with the addition of aromatics, and in some cases of a little calomel now and then; or in the tincture of rhubarb in wine. And the laxity of the fibres requires astringents, particularly such as have steel in their composition.

As to external or topical remedies, which I have said are necessary, when the vagina is the seat of the disease; we ought carefully to avoid applying all such as are powerful repellers of the peccant humours: for those only are serviceable which deterge and heal the little ulcers of that membrane. For my part, I have often, with great success, ordered the patient to inject a small quantity of Bates's aqua aluminosa, or of the camphorated vitriolic water, with a little Egyptian honey added to either, into the vagina through a proper syringe, at repeated times: and it will be of some service to fumigate the vagina now and then with a powder made with equal parts of frankincense, mastic, amber, and cinnabar of antimony, thrown on burning coals. *Mead's Morita Præcepta.*

FLUSH-DECK, or deck flush fore and aft, in ship-building, the upper deck of a ship, which has no rising at either end, only the common curve, or gradual ascent from the middle towards the stem and stern, called by sailors the sheer.

FLUTE, fistula, an instrument of music, the simplest of all those of the wind kind. It is played on by blowing it with the mouth, and the tones or notes are changed by stopping and opening the holes disposed for that purpose along its side. The ancient fistulæ, or flutes, were made of reeds, afterwards of wood, and last of metal: but how they were blown, whether as our flutes, or as hautboys, does not appear.

German FLUTE, is an instrument entirely different from the common flute. It is not, like that, put into the mouth to be played, but the end is stopp'd with a stopper, or plug; and the lower lip is applied to a hole about two inches and a half, or three

inches distant from the end. This instrument is usually about a foot and a half long; rather bigger at the upper end than the lower; and perforated with holes, besides that for the mouth, the lowest of which is stopp'd and opened by the little finger's pressing on a brass, or sometimes, a silver key, like those in hautboys, bassoons, &c. It is found exceeding sweet and agreeable, and serves as a treble in a concert.

FLUTES, or FLUTINGS, in architecture, perpendicular channels, or cavities, cut along the shaft of a column, or pilaster. They are chiefly affected in the Ionic order, where they had their first rise; though, indeed, they are used in all the richer orders, as the Corinthian and Composite; but seldom in the Doric, and scarce ever in the Tuscan.

Each column has twenty-four flutes, and each flute is hollowed in exactly a quadrant of a circle; but the Doric has but twenty. Between the flutes are little spaces that separate them, which Vitruvius calls *fria*, and we list: though, in the Doric, the flutes are frequently made to join to one another without any intermediate space at all; the list being sharpened off to a thin edge, which forms a part of each flute.

Sometimes the flutings are made flat, and are called *facettes*; but these have never such a good effect as the others. Vitruvius says, that when there are flutings in the column, there ought also to be eggs and anchors in the quarter-round of the capital, and even pearls and olives, in a baguette, to be made underneath, instead of annulets. These eggs and olives ought to be in the same number with the flutings, and to be regularly distributed.

FLUX, in medicine, an extraordinary issue, or evacuation, of some humours of the body.

FLUX of the urine. See **DIABETES**.

FLUX, in hydrography. See **TIDE**.

FLUX, in metallurgy, whatever can cause any body, otherwise not at all, or hardly, fusible by fire, to melt.

Fluxes, says Dr. Shaw, seem reducible to two general kinds, viz. the vitreous and the saline. By the vitreous we understand all those which either have of themselves, or readily assume, a glassy form in the fire; among the principal of which are reckoned the glass of lead, the glass of antimony, and borax. By the saline kind of fluxes are understood all those that are composed of salts, whether tartar, nitre, fixed alkali, or the like.

FLUXIONS, in the mathematics, according to their great inventor, are not magnitudes, but the velocities with which magnitudes (varying by a constant motion) increase or diminish; and the magnitudes thus generated are called the fluents of those fluxions. This definition is, as nearly as could possibly be expressed, the substance of the author's own words, in the introduction to his quadrature

drature of curves, where he says, " I consider mathematical quantities, in this place, not as consisting of very small parts, but as described by a continued motion. Lines are described, and thereby generated, not by the apposition of parts, but by the continued motion of points; superficies by the motion of lines, &c. therefore, considering that quantities which increase unequal times, and by increasing are generated, I sought a method of defining quantities from the velocities of the motions, or increments with which they are generated, and calling these velocities of the motions, or increments, fluxions, and the generated quantities, fluents, &c."

We have been the more particular in this definition that we might avoid the ill-natured criticisms of little pretenders to science; for we have very lately seen an author, of the most distinguished merit, treated in a very scurrilous manner for a small deviation therefrom, notwithstanding he has, by that means, conveyed the idea of a fluxion in a much more plain manner than had before been done; and, at the same time, no error could possibly arise in the application by considering them in that manner.

As the doctrine of fluxions is the most noble and comprehensive of all the mathematical sciences (for it may not improperly be called a science of itself) we shall, as we have done of the others, first give a short history of its rise and improvements, and the rather, as the invention has been claimed by two persons; in which we shall endeavour to demonstrate, that Sir Isaac Newton was the real and only inventor, and that Mr. Leibnitz only made some slight and trivial alterations from the hints he, from time to time, received from Mr. Oldenburgh, and the inventor himself; and secondly, explain the method itself, in the most plain and comprehensive manner possible.

Dr. Wallis, in his *Opus Arithmeticum*, published in 1657, cap. 33. prop. 68. reduced the fraction

$\frac{A}{1-R}$ by a continual division into the series $A +$

$AR + AR^2 + AR^3 + AR^4 +$, &c. Lord viscount Brounker squared the hyperbola by this series,

$\frac{1}{1 \times 2} + \frac{1}{3 \times 4} + \frac{1}{5 \times 6} + \frac{1}{7 \times 8} +$, &c. that is, by this $1 - \frac{1}{2} + \frac{1}{4} - \frac{1}{8} + \frac{1}{16} - \frac{1}{32} + \frac{1}{64} - \frac{1}{128} +$, &c. conjoining each two terms into one; which was published in the Philosophical Transactions for April 1668.

Soon after, M. Mercator published a demonstration of this quadrature by Dr. Wallis's division; and not long after that, Mr. James Gregory gave a geometrical demonstration thereof; and these books were, a few months after, sent by Mr. John Collins to Dr. Barrow at Cambridge, and by Dr. Barrow communicated to Mr. Newton in June 1669, then a fellow of Trinity college; whereupon Dr. Barrow sent Mr. Collins, in return, a tract of Mr. Newton's, entitled, *Analysis per aequationes numero terminorum infinitas*, and contains a general

method of doing that in all curves, which lord Brounker and M. Mercator did in the hyperbola alone; and though the latter lived upwards of ten years after, yet he never proceeded any farther than to the single quadrature of the hyperbola: the progress made by Mr. Newton as to all curves in general shews, that he did not want M. Mercator's assistance; however, to avoid cavilling, he allows that both lord Brounker had invented, and M. Mercator demonstrated the series for the hyperbola some years before they published it, and consequently before he himself had found out his general method.

This treatise is likewise mentioned by Mr. Newton himself, in a letter to Mr. Oldenburgh, dated October 24, 1676; also by several letters written by Mr. Collins to Mr. James Gregory in Scotland, Mr. Berlet and Mr. Vernon at Paris, as well as to several English gentlemen, viz. Mr. Storde, Mr. Oldenburgh, Mr. Dary, &c. These letters are dated in the years 1669, 1670, 1671, and 1672. Numberless other proofs might be brought to demonstrate that Mr. Newton had found out this method of determining the area of all sorts of curves and their rectification, together with the superficies and contents of solids from given right-lines, and *vice versa*, as he expresses himself in his above-mentioned letter to Mr. Oldenburgh, which he calls a compendium of these series.

Mr. Newton, in a letter to Mr. Oldenburgh, dated June 13, 1676, shewed, in a general manner, how to reduce any power of a binomial into a converging series; and also how, by that series, to square that curve whose ordinate is that power: therefore, by assuming, as is demonstrated by Dr. Wallis in his *Arithmetica Infinitorum*, that if the abscissa of any curve be x , m and n any integers, and the ordinate, at right-angles to the abscissa,

$\frac{m}{m+n} x^{\frac{m}{m+n}}$ the area of the figure will be $\frac{n}{m+n} x^{\frac{m+n}{m+n}}$; he

had a general expression for the area of all curves of that kind. This letter was communicated by Mr. Oldenburgh to Mr. Leibnitz, and Mr. Leibnitz afterwards desired a farther explanation of it, which was sent him in a letter dated October 24, following, from which it is plain that Mr. Leibnitz was so far from having invented any thing of this kind, that he did not, from the Compendium contained in that letter, fully understand it.

Moreover, Mr. Newton, in his above-mentioned Compendium, amongst many other examples, sets down this: Let the radius of a circle be 1, the arch z , and the sine x ; the equations for finding the arch whose sine is given, and for finding the sine whose arch is given, will be

$$z = x + \frac{1}{6} x^3 + \frac{3}{40} x^5 + \frac{5}{112} x^7, \&c.$$

$$x = z - \frac{1}{6} z^3 + \frac{3}{40} z^5 - \frac{5}{112} z^7 +, \&c.$$

Mr. Collins informed Mr. Gregory of this method in autumn 1669, and Mr. Gregory, by the

help of one of Mr. Newton's series, after a year's study, found out the method in December, 1670; and two months after, in a letter dated Feb. 15, 1671, sent several theorems, discovered thereby, to Mr. Collins, with leave to communicate them freely; and Mr. Collins was very free in communicating whatever he received either from Mr. Newton or Mr. Gregory, as appears by his letters printed in the *Commercium*; amongst the Series Mr. Gregory sent in the said letter, were these two; let the radius of a circle be r , the arch a , and the tangent t , the equations for finding the arch whose tangent is given, and the tangent whose arch is given, will be these:

$$a = t - \frac{t^3}{3r^2} + \frac{t^5}{5r^4} - \frac{t^7}{7r^6} +, \&c.$$

$$t = a + \frac{a^3}{3r^2} + \frac{2a^5}{15r^4} + \frac{17a^7}{315r^6} +, \&c.$$

In the year 1671, M. Leibnitz published two tracts at London, the one dedicated to the Royal Society, and the other to the Academy of Sciences at Paris; and in the dedication of the first he mentioned his correspondence with Mr. Oldenburgh: in Feb. 1673, M. Leibnitz, meeting with Dr. Pell at Mr. Boyle's, pretended to the differential method of Mouton; and notwithstanding Dr. Pell shewed him, that it was Mouton's method, he persisted in maintaining it to be his own invention, pretending that he had found it himself, without knowing what Mouton had done before, and that he had improved it much. When one of Mr. Newton's Series was sent to Mr. Gregory, he tried to deduce it from his own Series combined together, as he mentions in his letter, dated Dec. 19, 1670; and by some such method M. Leibnitz, before he left London, seems to have found the sum of a Series of fractions decreasing in *infinitum*, whose numerator is a given number, and the denominators triangular, pyramidal, or triangulo-triangular numbers, &c.

About the latter end of February or beginning of March 1673, M. Leibnitz went from London to Paris, and continued his correspondence with Mr. Oldenburgh to the following June; then he learned algebra and the higher geometry; and in July 1674 he renewed his correspondence with Mr. Oldenburgh and Mr. Collins, and he wrote, that he was master of a wonderful theorem, which gave accurately the area of a circle, or any sector thereof, in a series of rational numbers; and in October following, that he had found the circumference of a circle, in a series of very simple numbers, and that by the same method (so he calls the said theorem) any arch, whose sine was given, might be found in a like series, though the ratio to the whole circumference were not known; his theorem, therefore, amounted to the finding any sector or arch, whose sine was given; if the ratio of the arch to the whole circumference was not known, the theorem or method

gave him only the arch; if it was known it also gave him the whole circumference; and therefore it was the first of Mr. Newton's two theorems above-mentioned; but M. Leibnitz did not then know the demonstration of this theorem; for, in his letter of May 12, 1676, he desired Mr. Oldenburgh to procure the demonstration from Mr. Collins, meaning the method by which Mr. Newton had invented it.

In a letter of Mr. Collins's, dated April 15, 1675, Mr. Oldenburgh sent Mr. Leibnitz eight of Mr. Newton's and Mr. Gregory's series, amongst which were Mr. Newton's two series above-mentioned, for finding the arch, whose sine is given, and the sine whose arch is given; and Mr. Gregory's two series above-mentioned, for finding the arch whose tangent is given, and the tangent, whose arch is given; and Mr. Leibnitz, in his answer, dated May 20, 1675, acknowledged the receipt of this letter, and promised to compare them with those of his own invention, which he seemed to intimate had been invented many years before, but never took any farther notice of it, except to inform the public (in the *Acta Eruditorum*, for April, 1691) that he had invented something like it on that subject in the year 1675, at which time he had found out the demonstration of one of those series, and wrote to Mr. Oldenburgh to procure him Mr. Newton's demonstration of the others; this Mr. Newton did in a letter dated June 13, 1676, and which was sent to him at Paris, June 26, together with a manuscript, containing Extracts from Mr. James Gregory's Letters, who was now dead, and which contained all, or the greatest part, of his inventions of that kind, and which appears farther by Mr. Leibnitz's and Mr. Tschirnhause's answers concerning them.

M. Leibnitz's answer, directed to Mr. Oldenburgh, and dated August 27, 1676, begins thus, "Your letter, dated July 26, contains several, and those more extraordinary things in analysis, than a great many voluminous books published on this subject; wherefore, I thank both you, Mr. Newton, and Mr. Collins for communicating to me so many curious things;" and towards the end of the letter, after he had done with the contents of Mr. Newton's letter, he proceeds thus; "I come now to other things contained in your letter, which the learned Mr. Collins was pleased to communicate; I wish he had added the demonstration of Mr. Gregory's linear approximation, for he certainly had a genius for promoting such speculations." And M. Tschirnhause's answer, dated September 1, 1676, after he had done with Mr. Newton's letter about series, concludes thus, "and what that excellent geometrician Mr. Gregory has done in this matter are certainly extraordinary; and indeed such as shall cause his MSS to be published, shall do the greatest service to his reputation." In the first part of this letter

FLU

—, &c. Thus M. Leibnitz put in his claim for

A copy of a letter of Mr. Newton's, dated December the 10th, 1672, was likewise sent to M. Leibnitz by Mr. Oldenburgh, amongst Mr. James Gregory's papers, at the same time with Mr. Newton's letter of June 13, 1676. And Mr. Newton having mentioned in these two letters, that he had a very general analysis, partly consisting of the method of converging series, and partly of another method, whereby he applied those series to the solution of almost all problems, (excepting perhaps some numeral ones, like those of Diophantus) and found out the tangents, area's, lengths, solid contents, centres of gravity and curvities of curves, and curvilinear figures, either geometrical or mechanical, without sticking at furd's; and that Slu-

Slusius's method of tangents was but a branch or corollary of this other method; M. Leibnitz, having seen these in his return home through Holland, was then only meditating the improvement of Slusius's method; for, in a letter to Mr. Oldenburgh, dated from Amsterdam, November 13, 1676, he wrote thus; "the method of tangents, published by Slusius, does not reach so far but that something farther might be done in that kind, that would be of very great use in all sorts of problems, even in my method (without extractions) of reducing equations to series; to wit, a certain short table of tangents might be calculated and continued so far, till its progression appear, so that any one might continue it as far as he pleased, without any calculation." This was the improvement of Slusius's method into a general one, which M. Leibnitz was then meditating, and by his words, something farther might be done in that kind, that would be of very great use in all sorts of problems; but the improvement by the differential Calculus was not yet thought of, for that must be referred to the following year.

Mr. Newton in his next letter, dated October 24, 1676, mentioned the Analysis, communicated by Dr. Barrow to Mr. Collins in 1669, and also another tract written in 1671, about converging series, and about the other method, whereby tangents were drawn according to that of Slusius, and the Maxima and Minima determined, and the quadrature of curves made more easy, and this without ficking at radicals; and by which all series were invented, which in certain cases broke off, and gave the quadrature of curves in finite equations, when it might be done; and he comprehended the foundation of these operations in this sentence, expressed enigmatically as above, "having an equation given that involves any number of flowing quantities to find their fluxions, and *vice versa*:" which puts it past all dispute, that he had invented the method of fluxions before that time; and if other things in that letter be considered, it will appear, that he had then brought it to great perfection, and made it exceeding general; since the propositions in his book of quadratures, and the methods of converging series, and of drawing a curve line through any number of given points, were then known to him; for, when the method of fluxions does not proceed in finite equations, he reduces the equations into converging series by the binomial theorem, and by the extraction of fluents out of equations, either involving, or not involving their fluxions; and when finite equations are wanting, he deduces converging series from the conditions of the problem, by assuming the terms of the series gradually, and determining them by those conditions; and when fluents are to be deduced from fluxions, and the law of the fluxions is wanting, he finds that law very nearly, by drawing a parabolic line through any number of given points; and by these improve-

ments Mr. Newton had in those days made his method of fluxions much more universal than the differential method of M. Leibnitz is at present: this letter of Mr. Newton's, dated October 24, 1676, was seen by M. Leibnitz at London in the latter end of the winter, or beginning of the spring following, and he had a copy of it at Hanover the beginning of the ensuing spring; and M. Leibnitz soon after replied in a letter, dated June 21, 1677; "I agree with Mr. Newton, that Slusius's method of tangents is still imperfect; and I have long ago handled the subject more generally, viz. by the differences of the ordinates." Hence, for the future, calling dy the difference of the two nearest y , &c. Here at length M. Leibnitz first began to propose his differential method, and there is not the least evidence, that he knew it before the receipt of Mr. Newton's last letter; he says indeed, "that he had a long time ago handled the subject of tangents more generally, viz. by the differences of the ordinates;" and so he had affirmed before in other letters, that he had invented several converging series, both direct, and inverse, before he had any method of inventing them; and had forgot an inverse method of series before he perceived its usefulness; but no man is allowed a witness in his own cause, and therefore it lies upon M. Leibnitz's friends to prove, that he found out this method before the receipt of Mr. Newton's letters; and if they cannot prove this, the question, who was the first inventor of the method, is decided.

In November 1684, M. Leibnitz published the elements of this differential method in the *Acta Erudit.* which he illustrated with examples of drawing tangents, and determining Maxima and Minima, and then added; "and these indeed, are the rudiments of a certain kind of sublimer geometry, that reaches even to the most difficult, and curious problems of mixed mathematics, and which, without the differential calculus, or some such method, are not readily to be attempted." The words, some such method, plainly relate to Mr. Newton's; and that whole period contains nothing more than what Mr. Newton had affirmed of his general method in his letters of 1672 and 1676. And in the *Acta Erudit.* of June 1686, p. 297. M. Leibnitz added, "I choose rather to make use of dx and the like than of single letters, in their stead, because dx is a certain kind of modification of x itself, &c." He knew very well that in this method he might conveniently enough have used single letters with Dr. Barrow, but he chose rather to use the new symbols dx and dy , though nothing can be done by them, but what with more conciseness and advantage may be done by single letters.

The next year Mr. Newton's *Principia Philosoph.* came out, a book full of such problems, as M. Leibnitz called the most difficult and curious, &c. And the Marquis De l'Hospital speaks thus of it; "it is almost entirely composed by this calculus;" and

M. Leibnitz himself in a letter to Mr. Newton, dated from Hanover, March 27, 1693, and still extant in his own hand-writing, and exhibited to the Royal Society, acknowledged the same thing in these words; "you had surprisingly enlarged geometry by your series, but by your Principia you have shewn, that you have penetrated into what was beyond the reach of the common analysis; I have likewise attempted, by making use of proper symbols to express the sums and differences, to reduce in some measure to analysis, that geometry I call the transcendental, and I have not been unsuccessful."

The celebrated Dr. Wallis had received copies of Mr. Newton's two letters of June 13, and October 24, 1676, from Mr. Oldenburgh, and had published several things out of them in his algebra; soon after which he was advised to print the letters entire, because Mr. Newton's method of fluxions began to pass in Holland with great applause, under the title of Mr. Leibnitz's Method of Differentials, he therefore took notice of this in the preface to the first volume of his works, published in 1695; and in a letter to Mr. Leibnitz, he informs him of his reasons for so doing, which, though couched in pretty plain terms, Mr. Leibnitz never thought proper to contradict, or complain of, until after the doctor's decease, though in the *Acta Eruditorum*, for June, in the following year, he complains that the Dr. had not informed the public that he was master of the Calculus, when those letters passed between Mr. Oldenburgh and him.

This was the state of the dispute when Dr. Wallis died, which was in October, 1703. Till this time, Mr. Leibnitz pretended to nothing more than that he invented the method apart, without any assistance from Mr. Newton; he allowed that Mr. Newton was the older inventor, but Dr. Wallis being the last of the old mathematicians, who knew any thing of the beginning of the dispute, and he happily silenced, Mr. Leibnitz thought it a fair opportunity for putting in a farther claim, and, therefore, when Mr. Newton published his *Treatise on the Quadrature of Curves*, in 1704, Mr. Leibnitz, in the *Acta Erudit.* of January, 1705, in giving an account of this book, represented, that he was the first inventor of that method, and that Sir Isaac had only substituted fluxions for differences. This gave rise to the famous dispute between Mr. Keill and him; for Mr. Keill, in a letter published in the *Philosophical Transactions*, 1708, retorted the accusation, asserting that "Mr. Newton was, beyond all dispute, the first inventor of the arithmetic of fluxions, as would easily appear to any one that reads his letters, published by Dr. Wallis; though the same method, by only changing the name and manner of notation, was afterwards published by M. Leibnitz in the *Acta Erudit.*"

Before Mr. Newton saw what had been published

in the *Acta Erudit.* he expressed himself offended at the printing of this paragraph of Mr. Keill's letter; least it should cause a dispute; and M. Leibnitz, putting a worse construction on it than Mr. Keill intended, complained of it as a calumny in a letter to Dr. Sloane, dated March 4, 1711, N. S. and moved, that the Royal Society would cause Mr. Keill to make a public recantation: but Mr. Keill insisted he would prove and defend what he had written; and Mr. Newton, upon being shewn the accusation in the *Acta Erudit.* gave him leave so to do; but M. Leibnitz, in a second letter to Dr. Sloane, dated December 29, 1711, instead of making good his accusation, as he was bound to do, that it might not be deemed a calumny, insisted only upon his own candour, as if it would be injustice to question it; and refused to tell how he came by the method; and said that the *Acta Erudit.* had given every man his due, and that he had concealed the invention upwards of nine years (he should have said seven years) that no body might pretend (he means that Mr. Newton might not pretend) to have been before him in it; and called Mr. Keill a novice, unacquainted with things past, and one that acted without authority from Mr. Newton, and a clamorous man who deserved to be silenced, and desired, that Mr. Newton himself would give his opinion in the matter: he knew, that Mr. Keill affirmed nothing more than what Dr. Wallis had published thirteen years before, without being then contradicted: he knew, that Mr. Newton had given his opinion in this matter in the introduction to his book of quadratures, published before this controversy began; but Dr. Wallis was now dead; the surviving mathematicians in England are reckoned novices; M. Leibnitz would assume to himself to question any man's candour without injustice, and Mr. Newton, unless he would either dissemble or deny the matter, must be involved in wrangling and disputes.

The Royal Society, therefore, having as much authority over M. Leibnitz, as over Mr. Keill, as being two of their members, and being now twice pressed by M. Leibnitz to interpose, and thinking it unjust either to condemn, or censure Mr. Keill without enquiring into the matter; and knowing, that neither Mr. Newton, nor M. Leibnitz (the only persons alive who knew and remembered any thing of what had passed in these matters forty years before) could be witnesses for, or against Mr. Keill, appointed a numerous committee to search old letters and papers, and report their opinion upon what they should find; and as soon as this report was made, they ordered the letters and papers, with the report of their committee, to be published; and by these letters and papers it appeared, that Mr. Newton had the method in or before the year 1669, and that M. Leibnitz had it not before the year 1677.

So much for the historical part of this curious article.—We shall now proceed to deliver the principles thereof as briefly as a subject of so intricate a nature will permit. And first,

A fluxion, according to our definition, is the velocity with which any quantity, at any given point or term of it, flows; that is, increases or decreases.

Thus, if we suppose the indefinite right-line AE (plate LV. fig. 1.) to move with a parallel motion along the axis AX , or so as always to be parallel to its first situation; and, at the same time, suppose a point to move from A , along the said line AE , so as to generate or always to be in the curve AD : then, the velocity with which the end or point A , of the line AE , arrives at any point C , or, which is the same, the velocity with which the axis flows or is generated at any particular point C , is the fluxion of the absciss AC at that point: the velocity with which the point moves along the line AE at any point B , is the fluxion of the ordinate at that point: and, the velocity with which the point generates or moves along the curve at any particular point B , is the fluxion of the curve at that point. So likewise, the velocity with which the curvilinear space ACB flows, or is generated by the line AE , at any term CB , is the fluxion of the said curvilinear space at that time.

Now, if the velocity with which any quantity flows, or is generated, be at every point or term the same; that is, if it be neither accelerated or retarded; the fluxion of it will likewise be at every point or term the same: but, if this velocity be continually increased or diminished, then there will be a certain degree of velocity, or fluxion, peculiar to every point or term of the thing described: and the velocity wherewith the given velocity, at any point or term, is either accelerated or retarded, is called the fluxion of the fluxion, or the second fluxion. And, again, if this acceleration or retardation be not uniform, but is increased with different degrees of proportion at different points or terms, then the velocity or swiftness of this acceleration or retardation, is called the third fluxion. And so on.

Increment, is the indefinitely small increase of a quantity, generated in an indefinitely small particle of time.

Thus, if we suppose bc (fig. 2.) indefinitely near and parallel to the ordinate BC , and Be parallel to the absciss AC ; then Cc , or its equal Be , will be the increment of the absciss AC ; eb the increment of the ordinate CB ; Bb the increment of the curve AB ; and $CBbc$ the increment of the curvilinear space ABC .

Now, if nd be supposed indefinitely near and parallel to bc , and bm equal and parallel to Be or cd , then the difference between eb and mn , is called the increment of the increment, or the second increment; i.e. the increment of eb , or second increment of CB . And, again, if sf be supposed in-

definitely near and parallel to nd , and nr equal and parallel to bm or df , then the difference between the second increment, and the difference of mn and rs , is called the third increment of CB . And so on.

Note, when a quantity, instead of increasing, is continually diminished, then the indefinitely small particles, by which it is lessened, are not increments, but decrements; and both increments and decrements are sometimes called moments.

Now, if we suppose the absciss AC to flow on with an uniform motion, or equal parts of it to be described in equal times, its increment will accurately express, or be exactly as its fluxion; since velocity is always as the space uniformly described in a given time: and if the curve Bb did exactly coincide with the tangent or right-line TBG , it is evident, that then, the increments Bb and be , would likewise be described with uniform motions, and with the same degrees of velocity with which the curve and ordinate respectively flow at the point B ; that is, the increments Bb and be , would then be accurately as the fluxions of the curve and ordinate at the point B . But, since not two points of the curve are coincident with the tangent, and therefore the velocities with which the increments are generated, are continually varying in every point; so, therefore, the increments and fluxions are not in an exact proportion to each other; or, the increments do not accurately measure the velocities or fluxions with which they begin to be generated. However, as the point b is continually nearer to a coincidence with the tangent BG , the nearer it approaches the point of contact B ; so, therefore, if we conceive the ordinate Cb , to move back, till it coincides with CB ; then, the very first moment before its coincidence, the curve Bb and right-line BG , will be infinitely, or rather indefinitely near to a coincidence with each other; and consequently, in that case, the increments Bb and be will come indefinitely near to measure the fluxions of the curve and ordinate, or the velocities with which they respectively flow at the point B . Or, because the particles of time in which any increments are generated, are supposed to be indefinitely small, and consequently the acceleration or retardation of the velocity with which they are generated must be so too; therefore, they are indefinitely near in proportion to the fluxions of the quantities of which they are increments: but, when the ratio from that of equality, is but indefinitely small, or less than can be assigned, it may be considered as equal; and therefore, the increments may be taken as proportional to, or (because velocity is expressed by the space uniformly described in a given time) for the fluxions in all operations; and, on the contrary, the fluxions for the increments.

Note, those quantities which are supposed to flow, or to be generated by continual increase, are called,

called fluents, and variable or flowing quantities: and those which admit of no variation (as the parameter of a parabola, the diameter of a circle, &c.) are called permanent, given, and invariable quantities.—The beginning of the alphabet, viz. a, b, c, d , &c. is used to express invariable quantities; and the end, viz. z, y, x , &c. variable or flowing quantities: and the fluxions of those variables, viz. $\dot{z}, \dot{y}, \dot{x}$, &c. are respectively denoted by $\ddot{z}, \ddot{y}, \ddot{x}$, &c. and their second fluxions, or the fluxions of $\ddot{z}, \ddot{y}, \ddot{x}$, &c. by $\ddot{\ddot{z}}, \ddot{\ddot{y}}, \ddot{\ddot{x}}$, &c. and so on. Also, the moment, increment, or decrement, of z , is denoted by z' , of y by y' , of x by x' &c. and the second moments, increments, or decrements of $\dot{z}, \dot{y}, \dot{x}$, &c. or the moments, increments, or decrements of $\ddot{z}, \ddot{y}, \ddot{x}$, &c. by $\ddot{z}', \ddot{y}', \ddot{x}'$, &c. and so on.—The fluxions, increments, &c. of invariable quantities, viz. of a, b, c, d, e , &c. are $=0$.

Those fluents which are supposed to be generated in the same time, or in equal times, are called contemporary fluents; and the fluxions of these contemporary fluents, are called contemporary fluxions. Now, it is evident, if two or more of these contemporary fluents are always equal, or in any certain constant ratio to each other, that their contemporary fluxions will likewise be equal, or in the same proportion: and that, on the contrary, if two or more of these contemporary fluxions are always equal, or in any certain constant ratio to each other, their contemporary fluents will likewise be equal, or in the same proportion.

We come now to find the fluxions of fluents, or the velocities with which flowing quantities increase or decrease at any terms assigned; the business of which is called the Direct Method of Fluxions. But, before we proceed, it may, perhaps, be necessary to premise a few things concerning the different ways of expressing an algebraic quantity, by some called the New Notation, and which was first introduced by the celebrated Dr. Wallis, whom we have so often had occasion to mention in the former part of this article. Thus $\sqrt[3]{xx}$ may be expressed more commodiously by $x^{\frac{2}{3}}$, and $\sqrt[3]{xxx}$ by $x^{\frac{3}{3}}$, $\sqrt{a-x}$

by $\overline{a-x}^{\frac{1}{2}}$ and universally $\sqrt[n]{x^m} = x^{\frac{m}{n}}$.

Moreover it may be observed, that to divide any quantity by a power with an affirmative exponent, is the same as to multiply it by the same power with a negative exponent; as for example:

$$\frac{x}{a-y^{\frac{1}{2}}} = x \times \overline{a-y}^{-\frac{1}{2}} \text{ or } \frac{x}{\overline{a-y}^{\frac{m}{n}}} = x \times \overline{a-y}^{-\frac{m}{n}}$$

and the contrary. Also $x^2 \times x^{\frac{2}{3}} = x^{2+\frac{2}{3}} = x^{\frac{8}{3}}$;

$x^{\frac{2}{3}} = x^{3 \times \frac{2}{3}} = x^6$ and universally $x^m \times x^{\frac{m}{n}} = x^{m+n}$. The

observation of these hints may often be found of use in transforming of fluxions, which will sometimes be necessary before their fluents can be properly attained.

We shall now proceed to shew the method of finding the fluxion of a given fluent; for the doing of which observe the following rules.

Rule I. To find the fluxion of a simple fluent; or, of that wherein there is but one variable letter.

Mark the variable letter, or flowing term, with a dot over it.

Thus, the fluxion of ax is $a\dot{x}$.

For, if we suppose the variable rectangle AB , (fig. 3.) to be generated by the given line CB , setting out from the situation AD , and moving along with a parallel motion between the parallel and indefinite sides AC and DB ; it is evident, the velocity with which the rectangle flows, is equal to the generating line CB drawn into the velocity with which the point C generates, or moves along the line AC : that is, the fluxion of the rectangle AB , is equal to the invariable line CB drawn into the fluxion of the flowing or variable line AC . Therefore, if AD or $CB = a$, and AC or $DB = x$, then the fluxion of the rectangle ax will be $= a \times \dot{x} = a\dot{x}$.

Rule II. To find the fluxion of the product of two or more quantities drawn into each other.

Multiply the fluxion of each quantity separately, by the other, or the product of the rest of the quantities: and the sum of these products will be the fluxion required.

Thus, the fluxion of xy is $\dot{x}y + x\dot{y}$; the fluxion of axy is $\dot{a}xy + a\dot{x}y + ax\dot{y}$, i. e. $= a\dot{x}y + ax\dot{y}$; the fluxion of xyz is $\dot{x}yz + x\dot{y}z + xy\dot{z}$; and the fluxion of $axyz$ is $\dot{a}xyz + ax\dot{y}z + axy\dot{z}$.

1°. That the fluxion of xy is $\dot{x}y + x\dot{y}$, may be thus demonstrated.

Suppose a line, coincident with the indefinite right line AF , to move with a parallel motion along the indefinite right line AE ; and, at the same time, another, coincident with the line AE , to move with a parallel motion along the line AF ; and that the said two lines move with such different degrees of velocity, that their points of intersection may always be in the curve AI . Through any point B of the curve, draw CH parallel to AF , and DG parallel to AE . Then, by the line moving along the line AE , will the curvilinear space AEI and rectangle DE be generated; and, by the line moving along the line AF , the curvilinear space AEI and rectangle CF will be generated. Now, before the line moving along the line AE arrives at the situation CH , it is evident, that, the

curvilinear space AEI will increase slower, or flow with a less degree of velocity than the rectangle DE, and afterwards with a greater; therefore, at the term CB, they will flow with one and the same degree of velocity. So likewise, the curvilinear space AFI will flow or increase slower, or with a less degree of velocity, than the rectangle CF, before the generating line, moving along the line AF, comes to the situation DG; and afterwards, faster, or with a greater degree of velocity; and therefore, at the term DB, they will increase or flow with an equal degree of velocity. That is, the fluxion of the curvilinear space AEI, is, at the term CB, equal to the fluxion of the rectangle DE at the said term CB; and the fluxion of the curvilinear space AFI, is, at the term DB, equal to the fluxion of the rectangle CF at the term DB. But the fluxion of the rectangle DE, at the term CB, is equal to CB drawn into the fluxion of AC; and the fluxion of the rectangle CF, at the term DB, is equal to DB drawn into the fluxion of AD. Hence, therefore, the fluxion of the flowing rectangle ACBD (which is the sum of the two curvilinear spaces ACB and ADB), is equal to the sum of CB drawn into the fluxion of AC, added to DB drawn into the fluxion of AD: that is, if we put AC or DB = x , and AD or CB = y , the fluxion of the rectangle xy will be = $\dot{x}y + x\dot{y}$.

2^o. Hence, the fluxion of axy is = $a\dot{x}y + ax\dot{y}$; for, since xy is always in the fixt ratio to axy , of 1 to a ; therefore the fluxion of xy is to the fluxion of axy , as 1 to a : that is, $1:a::\dot{x}y + x\dot{y}:a\dot{x}y + ax\dot{y}$ is the fluxion of axy .

3^o. And, that the fluxion of xyz is = $\dot{x}yz + x\dot{y}z + xy\dot{z}$, may thus be proved. Let the length, breadth, and depth, of a parallelopipedon, be represented by x , y , and z , respectively. Now, this parallelopipedon will be equal to three pyramids, whose bases are xy , xz , and yz , and altitudes z , y , and x , respectively: and therefore, the sum of the fluxions of these pyramids, will be equal to the fluxion of the parallelopipedon xyz . Let either of the pyramids be represented as in fig. 4. by AEH or ACB, which suppose to be generated by the variable plane AF moving with a parallel motion along the indefinite right line AE; and, at the same time, let the parallelopipedon ADGE (whose face AD or EG is equal and similar to the base of the pyramid at the term CB), be generated by the plane AD, which is coincident with the plane AF. Now, it is plain, that the pyramid will increase slower, or flow with a less degree of velocity, than the parallelopipedon, before the generating planes arrive at the term CB; and afterwards faster, or with a greater degree of velocity: therefore, at the said term CB, they will flow, or be generated, with the same or an equal degree of velocity: but, it is likewise plain, that the velocity with which the parallelopipedon is generated, is equal to its face AD

or CB drawn into the velocity of its motion along the line or side AE; therefore, the velocity with which the pyramid is generated is, at the term CB, equal to its base CB drawn into the velocity of its motion, at the point C, along the side AE: that is, the fluxion of the pyramid ACB, is equal to its base CB drawn into the fluxion of its altitude AC. Hence then, when the base is xy , and altitude z , the fluxion of the pyramid is = $xy \times \dot{z}$ = $xy\dot{z}$; and, when the base is xz and altitude y , the fluxion of it is = $xz \times \dot{y}$ = $xz\dot{y}$; and, lastly, when the base is yz and altitude x , its fluxion is = $yz \times \dot{x}$ = xyz . Consequently, $\dot{x}yz + x\dot{y}z + xy\dot{z}$ (which is the sum of the fluxions of the three pyramids) is = the fluxion of the parallelopipedon xyz .

4^o. And that the fluxion of $axyz$ is = $a\dot{x}yz + a\dot{x}y\dot{z} + ax\dot{y}\dot{z}$, follows from the above Dem. 3^o. for since $xyz:axyz::1:a$, therefore $1:a::$ fluxion of xyz : fluxion of $axyz$; i. e. $1:a::\dot{x}yz + x\dot{y}\dot{z} + xy\dot{z}:a\dot{x}yz + a\dot{x}y\dot{z} + ax\dot{y}\dot{z}$ = the fluxion of $axyz$.

Rule III. To find the fluxion of a fraction.

Multiply the denominator into the fluxion of the numerator; from the product of which, subtract the numerator drawn into the fluxion of the denominator: then divide the remainder by the square of the denominator; and you will have the fluxion of the fraction required.

Thus, the fluxion of $\frac{x}{y}$ is = $\frac{\dot{x}y - x\dot{y}}{y^2}$

For, putting $z = \frac{x}{y}$; then $yz = x$; and the fluxion of this equation is $\dot{y}z + y\dot{z} = \dot{x}$; therefore, by transposition $y\dot{z} = \dot{x} - \dot{y}z$, and, by division, $\dot{z} = \frac{\dot{x} - y\dot{z}}{y}$; that is, (by restitution, or writing $\frac{x}{y}$ for z ,

its equal), $\dot{z} = \frac{\dot{x} - y \times \frac{x}{y}}{y} = \frac{\dot{x}y - x\dot{y}}{y^2}$ = the fluxion of $\frac{x}{y}$.

Hence, the fluxion of x^{-1} is = $-x^{-2}\dot{x}$; the fluxion of x^{-2} is = $-2x^{-3}\dot{x}$; the fluxion of x^{-3} is = $-3x^{-4}\dot{x}$; the fluxion of x^{-4} is = $-4x^{-5}\dot{x}$; &c. And, if m be made to represent any negative whole-number, the fluxion of x^m will be = $mx^{m-1}\dot{x}$.

Rule IV. To find the fluxion of an expression compounded of different terms or quantities connected together by the signs + and -.

Find the fluxion of each term by the preceding rules; which connect together with the signs of the respective terms, and you will have the fluxion required.

Thus the fluxion of $ax + y^2 - z$ is = $a\dot{x} + 2y\dot{y} - \dot{z}$. For, putting $ax + y^2 - z = v$; then $ax + y^2 = v + z$; and, it is evident, the sum of the fluxions of ax and y^2 must be equal to the sum of the fluxions of v and z ; that is, $a\dot{x} + 2y\dot{y} = \dot{v} + \dot{z}$; therefore, by trans-

transposition, $ax + 2y - z = \dot{v}$ the fluxion of $ax + y^2 - z$.

And, the fluxion of $x - a^2y + xy$ is $= \dot{x} - a^2\dot{y} + \dot{x}y$
 $+ x\dot{y}$. And, the fluxion of $ax^2 + x - \frac{x}{y}$ is $= 2ax\dot{x} + \dot{x} - \frac{\dot{x}y - x\dot{y}}{y^2}$.

Rule V. To find the fluxion of any power of a fluent or flowing quantity; whether the index be integral or fractional, affirmative or negative.

Multiply the whole term by the index of the power; then subtract 1 from the said index, and multiply this whole term by the fluxion of the root of the fluent; and you will have the fluxion of the power required.

Thus, the fluxion of $\overline{x+x^2}^3$ is $= 3x\overline{x+x^2}^2$ i. e. $= \overline{x+x^2}^2 \times 3x + 6xx$; the fluxion of $\overline{a+x}^{-2}$ is $= -2x\overline{a+x}^{-3} \times \dot{x}$, i. e. $= -\frac{2x}{\overline{a+x}^3}$
 $\times -2x$. And, universally, the fluxion of $\overline{x}^{\frac{m}{n}}$ is $= \frac{m}{n} \times \overline{x}^{\frac{m}{n}-1} \times \dot{x}$, i. e. $= \frac{m}{n} \overline{x}^{\frac{m}{n}-1} \dot{x}$; where, either m or n , or both, may be either integral or fractional, affirmative or negative: so that the index $\frac{m}{n}$ expresses, or represents, any affirmative or negative whole-number or fraction whatsoever.

Rule VI. To find the fluxion of a logarithm.

The fluxion of the hyperbolic logarithm of any quantity, is equal to the fluxion of that quantity, divided by the quantity itself.

Thus, the fluxion of the hyperbolic logarithm of x is $= \frac{\dot{x}}{x}$. The fluxion of the hyperbolic logarithm of $\frac{x}{a+x}$ is $= \frac{\dot{x}}{a+x}$. The fluxion of the hyperbolic logarithm of $\overline{x+a^2+x^2}^{\frac{1}{2}}$ is $= \frac{\dot{x}}{a^2+x^2}^{\frac{1}{2}}$.

Note. Hitherto we have supposed, when one variable quantity in any fluent increases, that the others, if any, increase likewise: but it often happens that some of them decrease, while the others increase; in which case, the fluxions of the decreasing are negative, with respect to those of the increasing quantities; and therefore, the signs of the terms which are affected with them, ought to be negative.

Thus, if whilst x increases, y decreases; the fluxion of the rectangle xy , will not be expressed by $\dot{x}y + x\dot{y}$, but by $\dot{x}y - x\dot{y}$.

For, let the flowing or variable rectangle AB , (fig. 5.) be continually increasing by the parallel motion of the variable line CB , moving from the situation AF along the line AE ; and, continually diminishing by the motion of the variable line DB ,

parallel to the line AE , and approaching towards it along the line FA ; that is, let the side $AC = DB$ continually increase, while the side $AD = CB$ continually decreases. Now (putting $AC = x$, and $AD = y$), it follows, that the fluxion of the increase will be $= \dot{x}y$, and that the fluxion of the decrease will be $= -x\dot{y}$; therefore the fluxion of the decrease, subtracted from the fluxion of the increase, leaves $\dot{x}y - x\dot{y}$ the fluxion of the rectangle xy ; or, the velocity with which it flows.

Understand the same of the fluxion of any fluent of a like nature whatsoever.

Inverse Method of FLUXIONS. See INVERSE.

FLY, in zoology, a large order of insects, the distinguishing characteristic of which is, that their wings are transparent; by this they are distinguished from beetles, butterflies, and grasshoppers.

FLY, in mechanics, a cross with leaden weights at its ends, or rather a heavy wheel at right angles to the axis of a windlass, jack, or the like; by means of which the force of the power, whatever it be, is not only preserved, but equally distributed in all parts of the revolution of the machine.

FLY-BEAT, or FLIGHT, in the Dutch marine, certain merchant-ships of a very clumsy, uncouth build, nearly similar to the genius of the builders: they are generally from four to six hundred tons, and distinguished by a very high stern, like a Gothic turret above, and very broad buttocks below. See BUTTOCK.

FLYERS, in architecture, such stairs as go straight, and do not wind round; nor have the steps made tapering, but the fore and back part of each stair, and the ends, respectively parallel to one another; so that if one flight do not carry you to your intended height, there is a broad half space, from whence you begin to fly again, with steps every where of the same length and breadth as before.

FLYING-ARMY, a small body under a lieutenant, or major general, sent to harrahs the country, intercept convoys, prevent the enemy's incursions, cover its own garrisons, and keep the enemy in continual alarm.

FLYING-BRIDGE. See the article BRIDGE.

FLYING-CAMP. See the article CAMP.

FLYING-FISH, a name given by the English writers to several species of fish, which, by means of their long fins, have a method of keeping themselves out of the water a long time.

FLYING-PINION is part of a clock, having a fly, or fan, whereby to gather air, and so bridle the rapidity of the clock's motion, when the weight descends in the striking part. See the article CLOCK.

FOAL, or COLT, the young of the horse kind. The word colt, among the dealers, is understood of the male kind.

FOCUS, in geometry and conic sections, is applied to certain points in the parabola, wherein the rays

rays reflected from all parts of these curves meet and concur.

The word is Latin, and literally signifies a fire-hearth.

Foci of an Ellipsis, are two points, as F f (Plate LV. fig. 8.) in the longest axis of the ellipsis; from each of which, if any two right-lines are drawn, meeting each other in the periphery of the ellipsis, as f N, F N, or f L, F L, their sum will be always equal to the longest axis; and therefore, when an ellipsis and its two principal axis are given, and the foci are required, you need only take half of the longest, or transverse axis, in your compasses, and setting one foot in the point where the shortest, or conjugate diameter, cuts the periphery, and the other foot will cut the longest axis in the foci required. See **ELLIPSIS**.

Focus of an Hyperbola is that point in the axis through which the latus rectum passes. See **CONIC Sections** and **HYPERBOLA**.

Focus of a Parabola is that point in the axis wherein the semi-ordinate is equal to the semi-parameter; or it is that point through which the latus rectum passes. See **CONIC Sections** and **PARABOLA**.

Focus, in optics, is the point wherein the rays are collected, after they have undergone refraction. See **MIRROR** and **LENS**.

It is so called because the sun's rays being united within a very small compass or circle, are greatly confipated and condensed; by which means their action or heat is proportionally increased and therefore objects posited in that point will be greatly heated, burnt, or melted.

Virtual Focus, in dioptrics, is the point from which the refracted rays, when they are rendered divergent by refraction, begin to diverge.

FODDER, any kind of meat for horses, or other cattle. In some places, hay and straw, mingled together, is peculiarly denominated fodder.

FODDER, in the civil law, is used for a prerogative that the prince has, to be provided of corn and other meats for his horses, by the subjects, in his warlike expeditions.

FODDER, in mining, a measure containing twenty-two hundred and an-half weight, though in London but twenty hundred weight.

FODINA, in anatomy, the labyrinth of the ear. See **EAR**.

FOECUNDITY, or **FECUNDITY**, the same with fertility. See the article **FERTILITY**.

FOENUGREEK, *Famum-gracum*, in botany, an annual plant, producing trifoliate leaves, placed alternately on a green, slender, hollow stalk, about a foot and a half high. The flowers proceed from the wings of the stalk, and are papilionaceous and white: these are succeeded by long compressed crooked pods, which contain a number of yellowish rhomboidal seeds.

This plant is cultivated in the fields, in the south of France, and in Germany. The seeds are used in medicine in cataplasms and fomentations, being emollient and discutient to a great degree. It is also prescribed in carminative and anodyne clysters to abate the acrimony of the humours, and to bestow a mucus on the corroded intestines.

FOETOR, in medicine, stinking or foetid effluvia, arising from the body, or any part thereof.

FOETUS, in physiology, denotes the child while it is contained in the mother's womb, but particularly after it is formed, till which time it is more properly called embryo. See the article **GENERATION**.

FOG, or **MIST**, a meteor, consisting of gross vapours, floating near the surface of the earth.

FOGAGE, in the forest law, is rank grass not eaten up in summer.

FOIL, among glass-grinders, a sheet of tin, with quicksilver or the like, laid on the backside of a looking-glass, to make it reflect.

FOIL, among jewellers, a thin leaf of metal placed under a precious stone, in order to make it look transparent, and give it an agreeable different colour, either deep or pale: thus, if you want a stone to be made of a pale colour, put a foil of that colour under it; or if you would have it deep, lay a dark one under it.

FOLIAGE, among botanists, particularly signifies the leaves of plants; though by some is applied to the petals of a flower. See **LEAF** and **COROLLA**.

FOLIATING of Looking-Glasses is performed by fixing quicksilver on the reverse surface, by means of plates of tin; which amalgamating or combining with the quicksilver, takes away its fluidity, and renders it so tenacious, as to be compressed into a very thin coat or plate, capable of adhering to the surface of the glass.

There are several manners of laying the quicksilver and tin on the glass; and it is by some practised, to use the quicksilver alone; and by others, to compound with it tin and lead; and bismuth has likewise been frequently used instead of them: but it is not necessary, when the operation is well conducted, to make any addition to the quicksilver. The following is one of the best methods hitherto practised.

“A proper number of sheets of thin paper must be procured; which paper should be of a soft spongy nature, like that called blotting paper. This paper must be spread on a table with a very level even surface, and fixed very firmly; or it is better to use a marble table or slab; but so much only of the table should be covered, as may form an area of the same figure with that of the glass to be silvered, a little enlarged. Over the surface of the paper must be sprinkled some powdered chalk; which should be rolled

rolled or beaten very thin, must then be laid upon the paper sprinkled with chalk, in the most smooth and even manner : and where there is occasion, on account of the size of the glass, to use more than one, they should be joined with great exactness, rather suffering nevertheless the edge of one to bear on the other, than leaving any deficiency ; so that the whole surface of the paper may be perfectly covered. Quicksilver is then to be poured upon these leaves of tin ; and spread over every part of it by a hare's foot, or the feathered part of a quill. The sheets of very thin smooth paper, of which the kind called fan paper is best, must be then laid over the quicksilver, leaving a margin beyond the quicksilver ; and upon this paper the glass must be gently laid : and then, being pressed down with the one hand, the paper must be gently drawn from under it with the other, by taking hold of the margin left for that purpose. The upper surface of the glass must then be covered with thicker paper, and a considerable weight put over it, in order to press out all the quicksilver that is not fixed by the tin ; as well as to make it adhere the more firmly to the glass. When no more quicksilver appears to drain off, the weights and paper may be removed ; and the operation will be complete."

Globes of glass may be silvered ; but as no pressure can be given, the plates of tin cannot be used ; and the quicksilver must therefore be rendered of a proper consistence, by amalgamating it with some of the other metallic substances. The most approved method of doing this is as follows.

" Take of quicksilver two parts, of bismuth two parts, and of tin and lead each one part. Melt the tin and lead together, and when they are fluid, add the bismuth ; when that is melted likewise, take them from the fire, and put the quicksilver gradually to them ; stirring the mixture till the whole be united. After the mass is become so cool, as not to endanger its breaking the glass, pour it into the globe to be silvered ; using a funnel, which will carry it to the bottom of the globe. Move the glass then gently about, so that the amalgamated matter may flow over every part, and adhere to it ; which will effectually silver the globe. When every part is covered, pour out the redundant quantity, and keep the glass still, till it be perfectly cool. If, during the operation, the mixture is set in the globe, and be not sufficiently liquid to flow about, and cohere with the glass, a gentle heat must be administered, which will remedy this defect ; and if, on the contrary, the matter appear too fluid, and have not sufficient tenacity to fix itself to the glass, it must be taken out, and an additional quantity of the bismuth, tin, and lead, added, by means of a proper heat."

FOLIATION, among botanists, signifies the complicate or folded state the leaves are in whilst they remain concealed within the buds of plants.

FOLIO, in merchant books, denotes a page, or

rather both the right and left hand pages, these being expressed by the same figure, and corresponding to each other. See BOOK-KEEPING.

FOLIO, among printers and booksellers, the largest form of books, when each sheet is printed, that it may be bound up in two leaves only.

FOMAHANT, or FOMALHANT, in astronomy, a star of the first magnitude in Aquarius, whose latitude is $29^{\circ} 19' 11''$ north, and longitude $27^{\circ} 23' 24''$ of Capricornus, according to Mr. Flamsteed's catalogue.

FOMENTATION, in medicine, the same with a liquid epithema, if applied hot ; and is the bathing of any part of the body in a proper liquor, commonly made by a decoction of herbs in water, wine, milk, &c. being generally applied by means of stupes or doubled flannels, dipped in the medicated decoction, and all the liquor, if very hot, expressed out of them, lest it should scald the part, raise blisters, &c. And it is farther observable, that a certain degree of heat will dissolve and dissipate a rumour, whilst a higher degree of it will harden and make it scirrhous.

The word is Latin, *fomentatio*, and derived from *fomento*, to foment.

FONT, among ecclesiastical writers, a large basin, in which water is kept for the baptizing of infants, or other persons.

It is so called probably because baptism was usually performed among the primitive Christians at springs or fountains.

FONTANELLA, in anatomy, the quadrangular aperture, between the os frontis and ossa sincipitis, in infants just born, which is also called fons pulsatilis.

FONTICULUS, or FONTANELLA, in surgery, an issue, seton, or small ulcer made in various parts of the body, in order to eliminate the latent corruption out of it. See ISSUE, SETON, &c.

FONTINALIA, in Roman antiquity, a religious feast celebrated on October 13, in honour of the nymphs of wells and fountains.

FONTINATIS, in botany, a genus of mosses. The male flower is almost sessile. The anthera is oblong, with an open mouth, and covered with smooth conic calyptræ.

FOOD implies whatever aliments are taken into the body, to nourish it. See DIET, DRINK, ALIMENT, &c.

FOOT, *Pes*, a part of the body of most animals, whereon they stand, walk, &c.

FOOT, in the Latin and Greek poetry, a metre or measure, composed of a certain number of long and short syllables.

FOOT, a longitudinal measure ; in England it is commonly divided into 12 inches, but by geometers into 10 digits, and every digit into 10 lines ; this latter kind of division is mostly observed in foreign nations : but the foot itself differs in length

in different countries; thus the English foot is to that of Paris as 1000 to 1068; to that of Dantzick as 1000 to 944; to the ancient Greek as 1000 to 1007; to the old Roman as 1000 to 970; and to that of Venice as 1000 to 1162.

FOOT-BANK, or **FOOT-STEP**, in fortification, the same with banquette. See the article **BANQUETTE**.

FOOT-HUSKS, among botanists, short heads, out of which flowers grow.

FOOT-LEVEL, among artificers, an instrument that serves as a foot-rule, a square, and a level. See the articles **LEVEL**, **RULE**, and **SQUARE**.

FOOT-PACE, or **HALF-PACE**, among carpenters, a pair of stairs, whereon, after four or six steps, you arrive at a broad place, where you may take two or three paces before you ascend another step. The design of which is to ease the legs in ascending the rest of the steps. See the article **STAIR-CASE**.

FOOT-ROPES, among sailors, the same with the horses of the yards. See the article **HORSE**.

FORAMEN, in anatomy, a name given to several apertures, or perforations in divers parts of the body; as, 1. The external and internal foramina of the cranium or skull. 2. The foramina in the upper and lower jaw. 3. Foramen lachrymale. 4. Foramen membranæ tympani.

FORAMEN OVALE, an oval aperture or passage through the heart of a fœtus, which closes up after birth.

FORCE of Bodies in Motion, or *Moving FORCE*, in physics, is that force with which bodies change their place. We do not here mean the stroke, pressure, or action, which causes this change of place in a body, but the force which it has while it is moving from one place to another, and may always be known by the effect which it is able to produce, that is by the stroke which the moving body can give, or by the resistance or obstacle which it is able to overcome. It may likewise be found mathematically, by multiplying the mass or quantity of matter contained in any body by its velocity.

The famous dispute on this subject which happened amongst the philosophers of the last age is of too extraordinary a nature to pass entirely unnoticed here. It was first begun between the celebrated Mr. Huygens, and the abbot Catalan, about the force of oscillating bodies; but the aforesaid abbot, and Mr. Leibnitz, whom we have had occasion to mention so often, were the two first who seem to have begun the dispute in earnest; the latter of these gentlemen declaring in express words, that the force of bodies are as their masses multiplied by the square of their velocities. He was answered by Catalan, and afterwards by Mr. Papin; he replied, and was replied to again; till at last one side or other was joined by all the philosophers in Europe: however, Leibnitz and his party proved

too weak to withstand the arguments of the other, backed by the Newtonian method of philosophizing, which depends only on facts and experiments: to counter-balance which, their opponents had recourse to critical distinctions, and metaphysical subtleties, to evade the force of their arguments, explaining and re-explaining, till at length they seem to have explained away their own meaning, if they might be said to have any at first. To say the truth, the dispute seems to have been occasioned by a mistake, and continued through a misunderstanding, whether a wilful one or not we cannot take upon ourselves to say; for when we say that the force of bodies in motion is as their velocity multiplied into their mass, we understand the action of those bodies to be instantaneous, for if time be taken into the consideration, the effects will be very different, and in some cases, when the action is applied to soft or yielding bodies, will approach very nearly to the squares of the velocities multiplied into the mass; as was asserted by Mr. Leibnitz and his followers.

Attractive FORCE. See **ATTRACTION**.

Central FORCE. See **CENTRAL FORCE**.

Centrifugal FORCE. See **CENTRIFUGAL FORCE**.

Centripetal FORCE. See **CENTRIPETAL FORCE**.

FORCE of the Heart. See **HEART**.

FORCE of the Wind. See **ANEMOMETER**.

FORCE, in law, signifies any unlawful violence offered to things or persons.

FORCEPS, in surgery, &c. an instrument that is well known, of which there are several sorts, adapted to various operations. Their uses are to lay hold of any thing and extract it from the body.

FORCER, or **FORCING-PUMP**, in mechanics, is a kind of pump in which there is a forcer or piston, without a valve. See **PUMP**.

FORCIBLE, in law, something done illegally. See the article **FORCE**.

FORCING, among gardeners, the raising of cucumbers, melons, strawberries, &c. on common hot-beds; also the producing ripe fruit from several sorts of trees before their usual season. Peaches, nectarines, cherries, and grapes, being the most valuable and admired wall-fruits, the common method of forcing them is as follows: The trees designed to be forced should be in good condition, with a good quantity of blowing wood; these should be covered with moveable glasses sloping from the top of the wall to about four feet and a half from the bottom, and closed at each end, these may be put on in February, as early forcing is liable to miscarriage: on the north side of the wall there should be a quantity of new horse-dung, placed sloping as the glasses on the other side, but wider; this will throw a considerable heat through the wall (which should not be too thick) and thereby cause (with the aid of the sun in front) the blossoms and leaves to come out quickly: when the heat of the dung is much abated, it may be necessary to remove it, and

and lay a fresh quantity in its stead. When the trees are in full flower, they should have a considerable share of air at all favourable opportunities, otherwise the blossoms will fall off, and, consequently, the crop miscarry; also it will be necessary to give the roots frequent refreshings of water, as likewise the branches, but this must be done in the morning, when there is an appearance of a sunny day.

But we think the following method of forcing preferable to the former; this is practised in Holland, and lately introduced in a few gardens in England, particularly at the earl of Ancram's, at Charlton in Kent, where they force peaches and nectarines in very great perfection without detriment to the trees. To give the reader a proper idea of the forcing-frame, we have exhibited in Plate LV. *fig. 7*, a sketch in perspective (the front end is the section) of one which contains two trees, and may be continued to any length at pleasure: the line *a* is the surface of the ground; *b* is the pit filled with new tan, which heats the frame; *c* is the space left to go in to manage the under part of the tree, and to gather the under fruit, which are almost as numerous as those on the upper-side; *d* is a lattice-work to train the trees on, at about ten inches below the glasses *f*. The roots of the trees are partly within the frame and partly without, extending within as far as the tan-bed *b*, the bottom of the stem being just within the lower part of the frame at *g*. The lights or glasses may be about four feet and a half or five feet wide, and six feet and a half long; each of which will contain a middling sized tree. It may asked how a tree can properly be planted to form the direction here described (which may make an angle of about forty degrees with the horizon); in answer to which, it is to be supposed that the tree has previously been trained against a wall, and consequently the major part of the roots have a direction but one way; therefore in planting the tree to force in this sort of a frame, it is only reversing it, that is, the side which was next the wall will be uppermost in the frame, and the roots downward, which will be of no detriment to it. The management, &c. is much the same as the former method of forcing; but, for the benefit of those who have an inclination to early raised fruits, we would by all means recommend this last form; and at the same time we cannot but disapprove of those forcing frames which have a flue in the wall, as it is so very drying, that few trees escape being pestered with a multitude of insects, which prey on them so much as finally to be their utter destruction, unless an almost continual washing the leaves and branches prevents it.

FORCING of Wine. See **WINE**.

FORE-CASTLE, in ship-building, a short deck which reaches from the top of the stem to the after part of the fore-throuds; or it commonly reaches as

far behind, or abaft, the fore-mast, as it is from the mast to the upper part of the stem.

FORE-CLOSED, in law, signifies the being shut out, and excluded, or barred, the equity of redemption on mortgages, &c.

FORE-FOOT, in ship-building, a piece of crooked timber, the lower part of which is bolted to the fore-end of the keel, of which it is a part, and the upper part laid on and bolted to the foot of the stem, of which it is also a part. See this fully explained in the article **SHIP-BUILDING**.

FORE-JUDGED, in law, signifies a judgment, whereby one is deprived, or put by a thing in question.

FORELAND, in the sea-language, the same with a cape. See the article **CAPE**.

FORELAND, in fortification, the same with *lizerie*. See the article **LIZIERE**.

FORE-LOCKS, little wedges of iron thrust to the ends of the bolts in a ship's side, to prevent them from drawing as the ships labours at sea.

FORELORN-Hope, in the military art, signifies men detached from several regiments, or otherwise appointed, to make the first attack in day of battle; or at a siege, to storm the counterescarp, mount the breach, or the like.

They are so called from the great danger they are unavoidably exposed to; but the word is old, and begins to be obsolete.

FORE-MAST. See the article **MAST**.

FORE-REACHING, or, in the sea-language, the act of making a greater progress forward than another ship; as the Tartar fore-reaches on the Eagle, i. e. advances quicker, or gains ground of her.

FORE-SKIN, in anatomy, the same with prepuce. See the article **PREPUCE**.

FOREST, *Sylva*, in general, a great wood, or a large extent of ground covered with trees.

FORE-STAFF, or **CROSS-STAFF**, a mathematical instrument used to take the sun's altitude.

FORESTALLER, a person who is guilty of forestalling.

FORESTALLING, in law, buying or bargaining for any corn, cattle, victuals, or merchandize, in the way as they come to fairs or markets to be sold, before they get thither, with an intent to sell the same again at a higher price.

FORESTER, a sworn officer of the forest, appointed by the king's letters patent, to walk the forest at all hours, watch over the vert and venison; also to make attachments and true presentments of all trespasses committed within the forest.

FORE-TOP-MAST. See the article **TOP-MAST**.

FORFEITURE, properly signifies the effect of transgressing some penal law, and extends to lands or goods.

Forfeiture differs from confiscation, in that the former is more general, whilst confiscation is particularly

ularly applied to such things as become forfeited to the king's exchequer; and goods confiscated, are said to be such as no person claims.

FOREFIELD, among miners, the farthest place of a meer of ground.

FORGE, properly signifies a little furnace, wherein smiths, and other artificers of iron or steel, &c. heat their metals red hot, in order to soften and render them more malleable and manageable on the anvil.

FORGERY, in a legal sense, is where a person fraudulently makes and publishes false writings to another's prejudice: or, it signifies the writ that lies against him who offends that way.

FORGING, in smithery, the beating or hammering iron on the anvil, after having first made it red hot in the forge, in order to extend it into various forms, and fashion it into works.

FORM, *forma*, in physics, the essential or distinguishing modification of the matter whereof a natural body is composed, so as thereby to give it such a particular manner of existence, being that which constitutes it such a particular body, and distinguishes it from every other body.

FORMS of Syllogisms, or *Syllogistic FORM*, among logicians, a just disposition both of the terms, in respect of predicate and subject; and of the propositions, in respect of quantity and quality: by which is only meant a disposition wherein the conclusion follows duly and legitimately from the two premises; there being no form where there is no conclusion. See the article **SYLLOGISM**.

FORM, in theology, is said to be one of the essential parts of the sacraments; being that which gives them their sacramental nature and efficacy, and consisting in certain words, which the priest pronounces in administering them.

FORM is also used in a moral sense, for the manner of being, or doing a thing according to rules; thus we say, a form of government, a form of argument, &c.

FORM, in law, the rules established and requisite to be observed in legal proceedings.

FORM, in carpentry, is used to denote the long seats or benches in the choirs of churches, or in schools, for the priests, prebendaries, religious, or scholars, to sit on.

At schools, the word form is frequently applied to what is otherwise termed a class. See **CLASS**.

FORM also denotes the external appearance or surface of a body, or the disposition of its parts, as to the length, breadth, and thickness. See the article **FIGURE**.

FORM is also used among mechanics, for a sort of mould, whereon any thing is fashioned or wrought; as the batter's form, the paper-maker's form, &c. See the article **HATTER**, &c.

Printer's FORM, an assemblage of letters, words, and lines, ranged in order, and so disposed into

pages by the compositor, from which, by means of ink and a press, the printed sheets are drawn.

Every form is inclosed in an iron chafe, wherein it is firmly locked by a number of pieces of wood; some long and narrow, and others of the form of wedges. See **PRINTING**.

FORMA PAUPERIS, in law, is where a person has just cause of suit, but is so poor that he cannot defray the usual charges of suing at law or in equity; in which case, on making oath that he is not worth five pounds in the world, on all his debts being paid, and producing a certificate from some lawyer that he has good cause of suit, the judge will admit him to sue in forma pauperis; that is, without paying any fee to counsellors, attorneys, clerks, &c.

FORMATION, in philosophy, an act whereby something is formed or produced.

FORMATION, in grammar, signifies the manner of forming one word from another; thus account-antship is formed from accountant, and this last from account.

FORMERS, in gunnery, round pieces of wood, fitted to the diameter of the bore of a gun, chiefly used for making cartridges.

On these formers, the paper, parchment, or cotton, which is to make the cartridge, are rolled before it be sewed.

FORMICA, the ant, in zoology. See the article **ANT**.

FORMICA-LEO, the ant-lion, or ant-eater, in zoology, an insect so called from its devouring great numbers of ants. It is the caterpillar or worm of a fly, much resembling the libellæ, or dragon-flies.

FORMING the line, in naval affairs, drawing up the ships of a squadron or division in a straight line, about an hundred and twenty fathoms distant from each other. See the article **LINE of Battle**.

FORMULA, or **FORMULARY**, a rule or model, or certain terms prescribed or agreed by authority, for the form and manner of an act, instrument, proceeding, or the like.

FORMULA, in medicine, imports the constitution of medicines, either simple or compound, both with respect to their prescription and consistence. Paracelsus calls red and clear urine, formula urine.

FORNICATION, the act of incontinency between single persons; for when either of the parties is married, such act is adultery. See **ADULTERY**.

FORNIX, in anatomy, a part of the brain placed under the septum lucidum, and, like it, composed of a medullary substance. Its anterior part rises with a double base, but the two parts soon unite: the hinder part is likewise bifid, and thence called crura fornicis, and by some, pedes hippocampi. See the article **BRAIN**.

FORRAGE, in the military art, denotes hay, oats, barley, wheat, grafs, clover, &c. brought into the camp by the troopers, for the sustenance of their horses.

Dry forage is the hay, oats, &c. delivered out of the magazines, to an army in garrison, or when they take the field, before the green forage is sufficiently grown up to supply the troops.

FORT, in the military art, a small fortified place, environed on all sides with a moat, rampart, and parapet. Its use is to secure some high ground, or the passage of a river, to make good an advantageous post, to defend the lines and quarters of a siege, &c.

Forts are made of different figures and extents, according as the ground requires. Some are fortified with bastions, others with demi-bastions. Some again are in form of a square, others of a pentagon. A fort differs from a citadel, as this last is built to command some town. See the article **CITADEL**.

Royal-FORT, one whose line of defence is at least twenty-six fathoms long.

Star-FORT, a redoubt formed by a number of re-entering and salient angles, the sides of which flank each other.

FORTIFICATION, the art of fortifying a town, or other place; or of putting them in such a posture of defence, that every one of its parts defends, and is defended by some other parts, by means of ramparts, parapets, moats, and other bulwarks; to the end, that a small number of men within may be able to defend themselves for a considerable time against the assaults of a numerous army without, so that the enemy, in attacking them, must of necessity, suffer great loss.

Fortification is either ancient or modern, regular or irregular. Ancient fortification, at first, consisted of walls or defences made of trunks, and other branches of trees, mixed with earth, to secure them against the attacks of the enemy. This was afterwards altered to stone-walls, on which were raised breast-works, behind which they made use of their darts and arrows in security. Modern fortification, is that which is flanked and defended by bastions and out-works, the ramparts of which are so solid, that they cannot be beat down but by the continual fire of several batteries of cannon.

Regular fortification, is that built in a regular polygon, the sides and angles of which are all equal, being commonly about a musket-shot from each other.

Irregular fortification, on the contrary, is that where the sides and angles are not uniform, equidistant, or equal; which is owing to the irregularity of the ground, valleys, rivers, hills, and the like.

The principal maxims of fortification are these:

1. That every part of the works be seen and defended by other parts, so that the enemy can lodge no where without being exposed to the fire of the place.
2. A fortress should command all places round it; and therefore all the out-works ought to be lower than the body of the place.
3. The works farthest from the center, ought always to be open to those

more near. 4. No line of defence should exceed a point-blank musket-shot, which is about an hundred and twenty, or an hundred and twenty-five, fathoms. 5. The more acute the angle at the center is, the stronger will be the place. 6. In great places, dry trenches are preferable to those filled with water, because sallies, retreats, and succours are frequently necessary; but, in small fortresses, water-trenches, that cannot be drained, are best, as standing in need of no sallies, &c.

Marine FORTIFICATIONS. Though these have nothing peculiar in them, yet it may not be improper to give some directions with relation to batteries. 1. In raising batteries to hinder a descent, care should be taken to dispose them in such places where the descent is most easy; and the guns should be so levelled as to scour the surface of the water, that they may fire effectually upon the boats as they approach. 2. It is likewise convenient to have batteries to play upon places where there is good anchorage; and these should be somewhat more elevated than the former. 3. It is also necessary to erect batteries at the entrance of roads; and these ought to be so made, as to discover ships at a distance. 4. It is very necessary that these batteries should be defended by some works, against attacks; and, if possible, should be under the fire of the place; or, at least, they ought not to be too far advanced.

FORTIN, **FORTLET**, or *Field-FORT*, a sence or little fort, whose flanked angles are generally distant one from another an hundred and twenty fathoms.

FORTISSIMO, in music, sometimes denoted by *FFF*, or *fff*, signifies to sing or play very loud or strong.

FORTUNE, *Fortuna*, a goddess worshipped with great devotion by the ancient Greeks and Romans, who believed her to preside over human affairs, and to distribute wealth and honour at her pleasure.

FORUM, in Roman antiquity, a public standing place within the city of Rome, where causes were judicially tried, and orations delivered to the people.

FOSS, or **Fossa**, in anatomy, a kind of cavity in a bone, with a large aperture, but no exit or perforation.

Foss is particularly used for the cavity, or indentation, in the back part of the neck.

Fossa MAGNA, the interior cavity, or *rima magna*, of the pudendum muliebre. Bartholin calls it *fossa navicularis*.

Foss, in fortification, a hollow place, commonly full of water, lying between the scarp and counter-scarp, below the rampart; and turning round a fortified place or a post that is to be defended. See **MOAT**.

Foss-WAY, one of the four principal high-ways of

of England, that anciently led through the kingdom; supposed to be made by the Romans, having a ditch upon one side thereof.

FOSSIL, in natural history, denotes, in general, every thing dug out of the earth, whether they be natives thereof, as metals, stones, salts, earthen, and other minerals; or extraneous, reposit in the bowels of the earth by some extraordinary means, as earthquakes, the deluge, &c.

FOVEA CORDIS, in anatomy, the pit of the heart, or rather of the stomach.

FOUGADE, or **FOUGASSE**, in the art of war, a little mine, about eight or ten feet wide, and ten or twelve deep, dug under some work or post, which is in danger of falling into the enemy's hands, and charged with sacks of powder, covered with stones, earth, and whatever else can make great destruction. It is set on fire like other mines, with a fauciffe.

FOUL, in the sea-language, entangled or embarrassed: foul anchor, i.e. an anchor which has either hooked its own or some other cable, wreck, rocks, &c. "a ship ran foul of us in the night," i.e. came close to our ship, entangling herself amongst our rigging.

FOUL-BOTTOM is when the bottom of a ship is covered with ooze, grass, shells, or other excrements.

FOUL-HAWSE is when the ship, being moored by two anchors, has turned round, and consequently twitted one cable about the other.

FOUL-WIND, a wind which blows contrary to the ship's course.

FOULNESS, in surgery, a term applied to wounds, where the flesh is putrid, fungous, black, or livid.

FOUNDATION, in architecture, is that part of a building which is under-ground.

Foundations are either natural or artificial. Natural, as when a building is erected upon a rock, or very solid earth, in which case we need not seek for any farther strengthening; for these, without digging, or other artificial helps, are of themselves fit to uphold the greatest buildings. But if the ground be sandy, or marshy, or hath lately been dug, recourse must be had to art. If the ground be sandy or marshy, you must dig till you find sound ground, and the best is that which requires most labour in cutting, and when wet does not dissolve into dirt. If the earth to be built upon is very soft, as in moorish grounds, lay good pieces of oak, whose length must be about the breadth of the trench, or two feet longer than the breadth of the wall, across the foundation, about two feet asunder, and being well rammed down, lay long planks upon them, pinning or spiking down each plank to the pieces of oak on which it lies. But if the ground be very bad, let piles of oak, of a diameter about one-twelfth part of their length, be drove down to

reach the good ground, and placed as close as one can stand by another; then spike down long planks upon them. And it must not be forgot to place the piles, not only under the outer walls, but also under the inner walls that divide the building; for if these should sink, it would make the outer wall crack, and so ruin the whole building. If the ground be faulty here and there, let arches be turned over the faulty places, which will discharge them of the weight. As to the rules necessary to be observed in the substruction or artificial part of the foundation, they are these: 1. That the bottom of the trench be made exactly level. 2. That the lowest ledge or row be all of stone (the broader the better) laid close together. 3. That the breadth of the ground-work be at least double that of the wall to be raised on it. However, the breadth may be regulated according to the goodness of the ground, and the weight of the intended edifice. 4. That the foundation be made to diminish as it rises, taking care, however, that it do so equally on both sides. 5. That you ought never to build on the ruins of an old foundation, unless well assured of its depth and strength to bear the superstructure. 6. And lastly, The stones in a foundation should be laid as they naturally lay in the quarry; a precept generally observed by all good architects, because they find the stones are subject to cleave that way of the grain that lay horizontally in the quarry. In some places buildings near the water are founded on sacks of wool laid like mattresses, which being well pressed and greasy, will never give way, nor rot in the water.

FOUNDATION of Bridges is laid after different manners. The first is by inclosing all the round space of ground you would build upon, by dams made with piles set deep in the ground in double rows, well strengthened and bound together with cross pieces and cords, and filling the vacant spaces between them with chalk or other earthy matter. This being done, the water must be emptied out, and the foundation dug according to the quality of the ground, driving down piles, if it be necessary, upon which the walls of the foundation must be laid. But this method is only practicable in building on such rivers, where the water is neither very rapid, nor very deep. The second is done by laying the foundation on grate-work, rafts of stout oak well bound together, and made fast at the surface of the water with cables or machines, and building upon them large quarters of stone, cramped together, and joined with good mortar, or cement, and afterwards letting them descend softly by these cables and machines perpendicularly to the bottom of the water. This was the method practised in laying the foundation of Westminster bridge, the grating being made of the bottom of a frame called by the French *caisson*, the sides of which were so contrived that they might be taken off, after a pier was finished.

ed. The third is by drawing off all, or the greatest part of the water of the river into some other place; and this was done at London-Bridge, if we could believe Stow, who alleges, that during the time of building, the river was turned from Battersea to Rotherhith; but this is not warranted.

FOUNDATION denotes also a donation or legacy either in money or lands, for the maintenance and support of some community, hospital, school, lecture, &c.

FOUNDAY, in metallurgy, a term used by the workers at the iron-mines in many counties in England, for the space of six days, in which time they continue to make a determinate quantity of iron; so that they count their work by these foundays, or weeks.

FOUNDER, in a general sense, the person who lays a foundation, or endows a church, school, religious house, or other charitable institution. The founder of a church may preserve to himself the right of patronage, or presentation to the living.

FOUNDER also implies an artist who casts metals, in various forms, for different uses, as guns, bells, statues, printing characters, candlesticks, buckles, &c. whence they are denominated gun-founders, bell-founders, figure-founders, letter-founders, founders of small works, &c. See **FOUNDRY**.

FOUNDER, in glass-making, a term appropriated to the crown and green glass, and is the person there, who in the same office in the white-glass making is called conciator.

FOUNDERING, in the menage, a disorder in horses, of which there are two kinds, viz. in the feet and in the chest.

Foundering in the feet, is an universal rheumatism, or defluxion of humours upon the sinews of a horse's feet, which causes so great a stiffness in the hoofs, that the horse has no sense or feeling of them.

This disorder arises from hard riding; from great heats and colds; and is sometimes occasioned by watering a horse when he is very hot, by which means, as the farriers term it, his grease is melted within him; also by wearing too straight a shoe, or travelling upon hard ground.

The general methods of curing this distemper are, first to pare all the horse's soles so thin, that you may see the quick: then bleed him well at every toe; stop the vein with tallow and rosin; and having tacked hollow shoes on his feet, stop them with bran, tar, and tallow, as boiling hot as may be; and this renew once in two days for a week together, after which, let him have good exercise, &c. or, after he is pared thin, and let blood at his toes, stop his feet with cow's dung, kitchen-fee, tar, and foot, boiled together, and poured boiling-hot into them.

Foundering in the chest may proceed from crudities in the stomach, or other infirmities, obstruct-

ing the passages of the lungs; and may be discovered by the horse's not being able to bow his joints; and being once laid, he cannot rise again; his legs swell, &c.

As a particular remedy for chest-foundering, take five or six pennyworth of oil of peter, and mingle it with an equal quantity of ale, or beer: then rub this mixture with your hand on the part affected; and cause a red-hot fire-shovel to be held before it during the application.

FOUNDERING, among sailors, sinking in a storm at sea.

FOUNDRY, or **FOUNDRY**, the art of casting all sorts of metals, into different forms. It likewise signifies the work-house, or smelting-hut, wherein these operations are performed.

FOUNT, or **FONT**, among printers, a set or quantity of letters, and all the appendages belonging thereto, as numeral characters, quadrates, points, &c. cast by a letter-founder, and sorted.

FOUNTAIN, *Fons*, a spring of living water that rises out of the ground. See **SPRING**.

Fountains or sources of rivers were held sacred among the ancients, and even worshipped as a kind of divinity: and it was a point of religion, not to muddy the waters in bathing.

Artificial FOUNTAIN, or *jet d'eau*, a contrivance, whereby water is violently spouted upwards.

Some fountains are founded on the elasticity of the air, and others on the pressure of the water.

The artificial fountain (*fig. 9.*) which may be set up upon either of its ends, after it has played out all its water in a jet through the spouting-pipe E, plays again afresh through the spout I, when you have turned it over like an hour-glass. The water contained in the cavity AFH runs down the curve pipe CDE, and spouts up through the jet E by the pressure of the column of water CD. But, unless the pipe GF was open at G, to let the air run up to F, and press at top of the surface of the water in the cavity A, the water could not run down and spout at E. There is such another pipe as GF at K, belonging to the cavity B, through which the water of the jet-received in the basin supplies the cavity B, whilst the fountain stands on the end B: but, when the fountain is inverted, it supplies B with air to let the water descend in the direction GHI, I becoming the spouting pipe.

Upon these principles depend also the alternate running and stopping of the fountain at command (*fig. 10.*) CAE is a receptacle of water close from the air's entrance, except through the pipe GF, when the cock C, by which it was filled, is stopped. There is another pipe EDHB, which goes from the bottom of the water to the jet B in the basin DB, but is stopped by the cock H. At the lowest part of the basin DB there is a small hole at I to let the water of the basin DB run into the basin,

basin GH under it: there is also a small triangular hole or notch in the bottom of the pipe FG at G. Turn the cock H, and the fountain will play some time; then stop, then play again alternately. The cause of playing and stopping is this; the water coming down the pipe EDHB would not come out at B, if the Ss above the water were not supplied, as it dilated: now it is supplied by the pipe GF, which takes it in at the notch G, and delivers it out at F; but after some time the water which has spouted out at B, falling down into the basin DB, rises high enough to come above the notch G, which stops the passage of the air, so that the air Ss above the water in the vessel CAE cannot sufficiently press for want of a supply, and the fountain ceases playing. Now the water of DB runs down into the lower basin HG, through the hole I, till it falls below the top of the notch G, and then the air runs up into the upper receptacle again, and supplying the air at Ss, the fountain plays again. This is seen a little before-hand by a skin of water on the notch G, before the air finds passage, and then you command the fountain to play. The hole I must be less than that of the jet, otherwise the water will all run out into the lower basin, without rising high enough to stop the notch G.

In the next fountain AB (fig. 11.) the air is condensed at the top of the water by means of a syringe, sometimes by blowing in; and the air and water are retained by the cock C, which must be opened, before it can play; then the water, strongly pressed by the condensed air at SS, goes through the pipe *a* and the adjutage *b* with great force, in jets of several figures according to the spouting-pipes put on at *b*.

In the fountain (fig. 12.) the air, being compressed by the concealed fall of waters, makes a jet, which seen for a while is looked upon as a perpetual motion by the ignorant.

The boxes CE and D Y X being close, you only see the basin ABW, with a hole at W, into which the water spouting out at B falls; but that water, going down the hole W, does not come up again at W, but runs down through the pipe WX into the box D Y X, from whence it drives out the air through the ascending pipe Y Z into the cavity of the box CE, where, pressing upon the water that is in it, it forces it out through the spouting-pipe OB, as long as there is any water in CE: so that this whole play is only whilst the water contained in CE, having spouted out, falls down through the pipe WX into the cavity D Y X. The force of the jet is proportional to the height of the pipe WX, or of the boxes CE and D Y X above each other. The height of the water, measured from the basin ABW to the surface of the water in the lower box D Y X, is always equal to the height measured from the top of the jet to the surface of the water in the middle cavity at CE. Now since the surface CE

is always falling, and the water in DY always rising, the height of the jet must continually decrease, till it is shorter by the height of the depth of the cavity CE, which is emptying, added to the depth of the cavity DY, which is always filling; and, when the jet is fallen so low, it immediately gives over. In the figure the air is represented by points.

To prepare this fountain, which is generally done privately first, pour in water at W, till the cavity DXY be full; then turn the fountain over, and the water will run from the cavity DXY into the cavity CE, which is full, when the water runs out at B held down. Set the fountain up again as if nothing had been done to it. When you would make it play, pour in about a pint of water into the basin ABW, and when the pipe WX is filled, the fountain will play, and continue so to do, as long as there is water in CE. You may pour the water left in the basin ABW into any vessel, and invert the fountain, which, when set upright, will be set a playing by putting back the water poured out into ABW; and so *toties quoties*.

FOURCHEE, or FOURCHY, in heraldry, an appellation given to a cross forked at the ends.

FOURCHER, or FOURCHING, in law, signifies the delaying or putting off an action, which might have been brought to a determination in a shorter time.

FOURTH, in music, one of the harmonic intervals. It consists in the mixture of two sounds, which are in the ratio of 4 to 3; that is, of sounds produced by chords, whose lengths are to each other as 4 to 3.

FOWL, among zoologists, denotes the larger sort of birds, whether domestic or wild: such are geese, pheasants, partridges, turkeys, ducks, &c.

FOX, *Vulpes*, in zoology, an animal of the dog-kind, which much resembles the common dog in form, and is of the size of a spaniel: it is chiefly distinguished by its long and straight tail, with the tip white.

The fox is a native of most northern countries. That of Siberia is about the size of a common kind; but its head is larger, and its tail not only bigger and more bushy, but all of one colour.

FOX-GLOVE, *Digitalis*, in botany, See DIGITALIS.

FRACHES, in glass-making, flat iron pans, wherein the new-made vessels are put, to be removed gradually from the fire.

FRACTION, in arithmetic, or, as it is sometimes called, a BROKEN NUMBER, is that which represents a part or parts of any thing proposed, and is generally expressed by two numbers placed one above the other, with a line drawn between them:

Thus $\frac{3}{4}$ is the numerator,
4 is the denominator,

The denominator denoting how many parts the thing

Then $72 \div 36 = 2$, the numerator; and $108 \div 36 = 3$, the denominator: therefore $\frac{72}{36}$ is abbreviated to $\frac{2}{3}$, the lowest terms.

Algebraical fractions are set down in every respect, and also managed in the same manner, as vulgar fractions; therefore, if vulgar fractions are well understood, these will be very easy; for, $\frac{a-b}{a}$, $\frac{a+b}{a}$, and $\frac{a}{b}$ of $\frac{a-b}{aa}$, are algebraic fractions which differ not in the least from vulgar ones in their nature and management.

For Addition, Subtraction, and Multiplication of FRACTIONS, See the articles ADDITION, SUBTRACTION, &c.

FRACTURE, in surgery, a rupture of a bone; or a solution of continuity in a bone, when it is crushed or broken by some external cause.

The word is Latin, *fractura*, and derived from *frango*, to break.

In curing fractures, the principal concern should be the agglutination of the bone: take care, therefore, 1. that it is reduced to its proper situation, and this is done by extension and reposition; 2. after reduction, apply a proper bandage, and prescribe rest to your patient; 3. prevent, or remedy, the inconveniencies that may ensue, and the surgeon will be qualified for this, if he knows, 1. how the bones are situated, whether there are one or more in the limb, whether they are large or small, robust or spongy, even or uneven, and whether one or more be fractured; 2. what muscles are near, with their position and office; 3. Whether any of the larger nerves, veins, or arteries, are near; for a thorough knowledge of these things conduces very much to a successful cure.

When the fractured bones continue in their natural position, a proper bandage will promote the agglutination of the fragments, without reposition or extension; though, as often as they recede from each other, some degree of extension is absolutely necessary, which must always be proportioned to the distortion of the fragments; for the wider the separation and the shorter the limb, from a contraction of the muscles, the greater extension is required. But this operation must be performed tenderly, lest too great violence should injure the patient.

In extending a fractured limb, care is to be taken, 1. that the patient is kept steady, to prevent his giving way to the extension. The posture must be accommodated to the circumstances; for sometimes sitting in a chair, or on the floor, sometimes lying on a bed, or table, is more commodious. 2. The broken limb, both above and below the fracture, must be held by an assistant. 3. The assistant who holds the lower part, must extend it with strength sufficient to replace the fragments; but, if the hands alone are not sufficient, use a rope or napkin; and if one man is not enough, employ two or three. Observe always to proceed with tenderness, that

you may not rack the patient with unnecessary tortures.

There remains one very important observation relative to the extension of fractured bones, which is, that if the surgeon is called in after tumours, or violent inflammations come on, he ought to defer the extension, till they are removed; for, under these circumstances, the parts affected cannot be handled, compressed, or extended, without much acute pains, convulsions, and the danger of a sphacelus: but if the tumor or inflammation are slight, we may easily proceed to extension directly, in order to prevent their increase.

FRÆNUM, in anatomy, a term applied to some membranous ligaments of the body. As,

FRÆNUM LINGUÆ, the ligament under the tongue; which sometimes ties it down too close to the bottom of the mouth, and then requires to be incised or divided, in order to give this organ its proper and free motion. This disorder generally arises in infants soon after their birth, so that they cannot move and exert their tongues in the action of sucking: though it is sometimes also observed in adults.

Each of the lips has also its peculiar frænum: the upper one under the nose; the under one near the roots of the dentes incisores: these are of the utmost service to us in speaking, and eating and drinking.

FRÆNUM PENIS, a ligament of the penis, that ties the prepuce to the lower part of the glans of the penis. See **PENIS**.

There is also a small frænum of the clitoris, by which it is connected to the ossa pubis. See the article **CLITORIS**.

FRAGARIA, the strawberry, in botany. See the article **STRAWBERRY**.

FRAIL, a basket made of rushes, or the like, in which are packed up figs, raisins, &c. It signifies also a certain quantity of raisins, about seventy-five pounds.

FRAISE, in fortification, a kind of defence, consisting of pointed stakes, six or seven feet long, driven parallel to the horizon into the retrenchments of a camp, a half-moon, or the like, to prevent any approach or scalade.

Fraises differ from palisades chiefly from this, that the latter stand perpendicular to the horizon, and the former jet out parallel to the horizon, or nearly so, being usually made a little sloping, or with points hanging down. Fraises are chiefly used in retrenchments and other works thrown up of earth; sometimes they are found under the parapet of a rampart, serving instead of the cordon of stone used in stone works.

To **FRAISE a Battalion**, is to line the musketeers round with pikes, that, in case they should be charged with a body of horse, the pikes being presented, may cover the musketeers from the shock of the horse, and serve as a barricade.

FRAME,

FRAME, in joinery, a kind of case, wherein a thing is set or inclosed, or even supported, as a window-frame, a picture-frame, &c.

FRAME is also a machine used in divers arts; as, **FRAME**, among printers, is the stand which supports the cases. See the article **CASE**.

FRAME, among founders, a kind of ledge inclosing a board, which, being filled with wetted sand, serves as a mould to cast their works in.

FRAME is more particularly used for a sort of loom, whereon artificers stretch their linens, silks, stuffs, &c. to be embroidered, quilted, or the like.

FRAME, among painters, a kind of square, consisting of four long slips of wood joined together, whose intermediate space is divided by threads into several little squares like a net; and hence sometimes called *reticula*. It serves to reduce figures from great to small; or, on the contrary, to augment their size from small to great.

FRAMING, a term used among gardeners, for the boxes and lights which cover the plants raised on common hot-beds.

FRAMING of an Houfe, among carpenters, denotes all the timber-work therein; namely, the carcase, flooring, partitioning, roofing, cieling, beams, athlring, &c. all together.

FRANCHISE, in a general sense, a privilege or exemption from ordinary jurisdiction; as that for a corporation to hold pleas among themselves to such a value, or the like.

FRANCHISE is sometimes used for an immunity from a tribute, in which sense it is either personal or real; that is, belonging to a person immediately, or else by means of this or that place of which he is chief, or a member.

FRANCHISE is also used for an asylum or sanctuary, where people are secure of their persons. See **ASYLUM**.

FRANCISCAN MONKS, **FRIARS-MINOR**, or **GREY-FRIARS**, religious of the order of St. Francis; founded by him in the year 1209.

FRANGULA, black berry bearing alder, in botany, a plant with a woody stem, with many irregular branches covered with a dark bark; these are furnished with oval spear-shaped leaves. The flowers are produced in clusters at the ends of the former year's shoots; these are very small, erect, and apetalous, of an herbaceous colour, and contains five stamina. The flowers are succeeded by small round berries, which are first red, but when ripe turn black. It flowers in June, and the berries ripen in September.

FRANKENIA, in botany, a genus of plants whose flower contains five petals, with a plane border and six filaments, topped with twin antheræ. The fruit is an oval, unilocular, and trivalvular capsule, containing a great many ovated very small seeds.

FRANK LANGUAGE, or **LINGUA FRANCA**,

a kind of jargon spoken in the Mediterranean, and particularly throughout the coasts and parts of the Levant, composed of Italian, Spanish, French, vulgar Greek, and other languages.

FRANK-LAW, a word applied to the free and common law of the land, or the benefit a person has by it.

FRANK-PLEDGE, in our law, signifies a pledge or surety for the behaviour of freemen.

FRANKINCENSE, *Thus*, in the materia medica. See the article **THUS**.

FRANKS, **FRANKIS**, or **FRANQUIS**, an appellation given by the Turks, and other nations of Asia, to all the inhabitants of the western parts of Europe, to which they give the name of *Frankistan*.

FRAPPING, among sailors, the act of crossing and drawing together the several parts of a tackle, or other complication of ropes drawn tight to secure any body. The frapping always increases the tightness, or of course adds to the security acquired by the purchase.

FRAPPING a Ship, passing four, five, or six turns of a cable round the body or hull of a ship in the middle, to secure her in a great storm, when it is apprehended she has not sufficient strength to resist the violent efforts of the waves: this expedient, however, is rarely put in practice, unless in very old ships, which the owners are willing to venture till the last.

FRATERNITY, in the Roman catholic countries, signifies a society for the improvement of devotion.

FRATERNITY, in a civil sense, a company or guild of certain artificers or traders. See the articles **COMPANY** and **GILD**.

FRATRICELLI, **LITTLE BROTHERS**, in church history, a sect of heretics who appeared in Italy about the year 1298, and afterwards spread all over Europe. They wore the habit of the Franciscan order, and pretended that ecclesiastics ought to have no possessions of their own.

FRATRIAGE, *Fratriagium*, the partition among brothers or coheirs, coming to the same inheritance or succession.

FRATRICIDE, the crime of murdering one's brother. See **PARRICIDE**.

FRAUD, in law, signifies deceit in grants or conveyances of lands, &c. or in bargains and sales of goods, &c. to the damage of another person.

FRAXINELLA, in botany. See **DICTAMNUS**.

FRAXINUS, the ash-tree, in botany. See the article **ASH**.

FREAM, a name given by farmers to ploughed lands worn out of heart, and laid fallow till it recovers. See **FALLOWING**.

FRECKLES, *Lentigines*, in medicine, small, yellowish, or dusky spots appearing on the skin, chiefly about the face, neck, and hands. It is mostly

mostly a natural affection caused by the heat of the sun, whereby some parts of the skin appear of a darker colour than usual, called tan, sunburn, and morpew, which differ only in degree, and usually disappear in winter.

Mr. Homberg's medicine, which is composed of bullock's gall mixed with alum, and after the alum is precipitated, exposed three or four months in the sun in a close phial, is the best remedy.

FREE, in a general sense, is used in opposition to whatever is constrained or necessitated. When applied to things endowed with understanding, it more peculiarly relates to the liberty of the will.

FREE-BENCH, signifies that estate in copyhold which the wife, being espoused a virgin, has after the decease of her husband for her dower, according to the custom of the manor.

FREE STATE, a republic governed by magistrates elected by the free suffrages of the inhabitants.

FREE-STONE, a whitish stone dug up in many parts of England, that works like alabaster, but is more hard and durable; being of excellent use in building, &c. It is a kind of a grit stone, and is called free, from its being of such a constitution as to cut freely in any direction: such is the Portland-stone, and the free-stone of Kent.

FREE-THINKER. See the article DEIST.

FREE-WARREN, the power of granting or denying licence to any one to hunt in such and such ground.

FREE the Boat, or bale the boat, among sailors, throw out the water.

FREEDOM, in general, the state or quality of being free.

FREEDOM of a Corporation, the right of enjoying all the privileges and immunities belonging to it.

FREEDOM of the Will, that power or faculty of the mind, whereby it is capable of acting, chusing, or rejecting, whatever it judges proper.

FREEDOM of Contrariety, among moralists, that of chusing either of two opposites, as virtue or vice, good or evil; concerning which the received doctrine is, that mankind have a freedom of contradiction, but not of contrariety; that is, they may abstain from the pursuit of virtue and good, but are incapable of hating them, or of preferring their opposites.

FREEZE, or FRIEZE, in architecture. See the article FRIEZE.

FREEZE, or FRIEZE, in commerce, a coarse kind of woollen stuff, or cloth, for winter wear; so called, as being freezed or napped on one side.

FREEZING, in natural philosophy, the same with CONGELATION, which see.

The principle which authors have gone upon, in order to solve the phenomena of freezing, are

either, first, according to Gassendus, that some foreign matter is introduced into the pores of the fluid, by means whereof its bulk is increased, and its parts become fixed.

And these gentlemen, to solve it, apply to certain nitrous particles, properly formed to produce this effect; in regard sal ammoniac, saltpetre, salt of urine, and many other volatile and alkalizate salts, mixed with water, increase its degree of cold very sensibly. And the manner in which these particles are presumed to hinder the fluidity of water is, that they are constituted of rigid pointed spicula, easily, they say, driven into the globules of water, which, being variously mingled, and as it were intertangled together, by degrees enfeeble, and finally destroy the motion thereof.

Secondly, the followers of Des Cartes assert, that some matter, naturally contained in the fluid, is by an intense degree of cold expelled, through the absence of which, the body becomes fixed. And this they presume to be brought about by the recess of the active, æthereal matter, to which they ascribe all motion of bodies, out of the pores of the water, or at least to a very large abatement of it. And considering the known phenomena of the freezing of the natural fluids (the attraction and repulsion of whose parts in a state of fluidity are pretty near equal, and therefore easily moved one against another; as also from the melting of such as are only reduced to a state of fluidity by heat, the parts being put under a degree of extraordinary vibration, which by cold again becomes rigid, wherein the attraction of their parts seems greatly to overpower that of their repulsion; whence proceeds what we call cohesion, tenacity, viscosity, and the like) we cannot refuse either of the systems above-mentioned, since neither of them at present come under proof by any experiment: they are therefore purely hypotheticalal.

But the third opinion on this subject, according to a late French author, is, that there is some alteration produced in the texture or form either of the fluid particles, or of something contained in them.

In favour of this last, it may be observed, that a globule of water held on the point of a needle, in a smart frost, will, upon freezing, shoot itself out into a star, having a certain number of points; and snow, which is a frozen vapour, seems to be no more than a congeries of these stars, united to each other by the tips of those points, and by no means adapting themselves to, or filling the interstices between them: it must therefore follow, that the dimensions of a quantity of water, reduced thus by cold from a fluid to a fixed state, will be considerably enlarged.

FREEZING, in naval affairs, a sort of ornamental painting, consisting of trophies, flower-work, &c.

on a ship's quarter, stern, or fore part immediately below the upper-edge of her sides, called the gunnel.

FRIEZING-MIXTURE, a composition of snow, or ice pulverized, mixed with nitre, or any other penetrating salt, which will cause so intense a degree of cold, as to fix or congeal the mercury in the thermometer. See **COLD**.

FREIGHT, or **FRAIGHT**, in navigation and commerce, the hire of a ship, or a part thereof, for the conveyance and carriage of goods from one port or place to another; or the sum agreed on between the owner and the merchant, for the hire and use of a vessel.

FREIGHT, is also used for the burden or lading of a ship, or the cargo of goods, &c. which she has on board.

FREIGHT also signifies a duty of fifty sols per tun, paid to the crown of France by the masters of foreign vessels going in or out of the several ports of that kingdom.

FRENUM, or **FRÆNUM**, in anatomy. See **FRÆNUM**.

FRENZY, or **PHRENZY**, in medicine. See the article **PHRENZY**.

FRESCO, a method of painting in relievo on walls, so as to endure the weather.

It is performed with water-colours on fresh plaster; or on a wall laid with mortar not yet dry. This sort of painting has a great advantage by its incorporating with the mortar, and drying along with it, becomes very durable.

FRESHEN the Hawse, among sailors, when a ship rides at anchor, there is always some canvas, mat, leather, or such like matter, wound about the cable in the hawse-hole, and where it may rub against the stem: the matter used on this occasion is called service, and, as by the pitching and labouring of a ship in a storm when she is anchored in an open road or bay, the service must be in a short time wore through, it is necessary to have it frequently renewed for the preservation of the cable, on which all depends; and this act of renewing the service is called freshening the hawse, which is a circumstance a seaman can never be too careful in observing. See the article **HAWSE**.

FRESHES, among sailors, the violence of an abb-tide, increased by heavy rains, flowing into the sea, which it discolours to a considerable distance from the shore on such occasions, where the line on which the two colours meet, may be distinctly observed for a considerable length along the coast.

FRET, or **FRETTE**, in architecture, a kind of knot or ornament, consisting of two lists or small fillets variously interlaced or interwoven, and running at parallel distances equal to their breadth.

Every return and intersection of these frets must be at right angles, otherwise they lose all the beauty, and become perfectly Gothic. Sometimes the

fret consists but of a single fillet, which, if well disposed, may be made to fill its space exceeding well. Frets were very much used by the ancients, especially on even flat members, or parts of a building, as the faces of the corona, and eaves of corniches; under the roofs, soffits, &c. and on the plinths of bases. See the articles **CORONA**, **EVE**, &c.

FRET, in heraldry, a bearing composed of fix bars, crossed, and variously interlaced; some call it the true lover's knot.

FRET, in music, signifies a kind of stop on some instruments, particularly bass-viol and lutes. Frets consist of strings tied round the neck of the instrument, at certain distances, within which such and such notes are to be found.

FRET-WORK, that adorned with frets. It is sometimes used to fill up and enrich flat empty spaces; but is mostly practised in roofs, which are fretted over with plaster-work. The Italians also use fretworks in the mantling of chimneys with great figures; a cheap piece of magnificence, and as durable almost within doors, as harder matters in the weather.

FRETTY, in heraldry, an appellation given to bearings made up of fix, eight, or more bars laid across each other, in the manner of frets.

FRIABLE, among naturalists, an appellation given to bodies that are easily crumbled to pieces: such are the free-stone, pumice-stone, &c.

FRIAR, or **FRIER**, from the French *frere*, a brother, a term common to monks of all orders, founded on this, that there is a kind of fraternity, or brotherhood, between the several religious persons of the same convent or monastery.

FRIAR'S COUL, in botany, a name given to several species of arum. See the article **ARUM**.

FRICTION, the rubbing or chafing of the surface of one body against another: thus when one body insists on another upon an horizontal plane, it presses it with all its weight, which being equally re-acted on (and therefore the whole effect of its gravity destroyed) by the plane, it will be absolutely free to move in any lateral or horizontal direction by any the least power applied thereto, provided both the touching surfaces be perfectly smooth or even.

But since we find no such thing as perfect politure or evenness in the surfaces of bodies (at least such as are produced by art) but an evident roughness or unevenness of the parts in the surface, arising from the porosity and peculiar texture of the body, it is easy to understand that when two such surfaces come together, the prominent parts of the one will in some measure fall into the concave parts of the other, and therefore, when an horizontal motion is attempted in one, the fixed prominent parts of the other will give more or less resistance to the moving surface, by holding and detaining its parts, which is what we call friction.

Now

Now since any body will require a force proportional to its weight to draw it over a given obstacle, it follows that the friction arising to the moving body will always be in proportion to its weight only, and not the quantity of the surface, by which it bears upon the resisting plane or surface. Thus if a piece of wood four inches wide, and one inch thick, be ground, and thereby made exactly fit to the surface of another fixed piece of the same wood, it will require the same weight to draw it along on the same, whether it be laid on its broad or narrow side.

For though on the broad side there be four times the number of touching particles (*cæteris paribus*) yet each particle is pressed with but $\frac{1}{4}$ of the weight that those are on the narrow side; and since four times the number multiplied by $\frac{1}{4}$ of the weight, is equal to $\frac{1}{4}$ of the number multiplied by four times the weight, it is plain the effect, that is the resistance, is equal in both cases, and so requires the same force to overcome it.

The reason why the friction is proportional to the weight of the moving body, is, because the power applied to move the body must raise it in some measure upon and over the prominent parts of the surface upon which it is drawn; and this motion of the body, as it is not upright, so it will not require a power equal to its whole weight; but being in the nature of the motion on an inclined plane, (since the body bears on the prominent parts all the while) the power which moves it will be proportional to but a part of its weight only; and this will vary with the various degrees of smoothness or asperity between the rubbing surfaces, and the other concurring circumstances.

We find by experiment, that a body ABCD (Plate LVI. fig. 1.) of wood, brass, &c. laid on the surface EFGH, will be drawn along by the weight P, nearly equal to one third of its own weight; if the surfaces be hard and well polished, it will be less than a third part; but if the parts be soft or rugged, it will be much greater. Thus also the cylinder of wood AB (fig. 2.) if very smooth, and laid on two well-polished supporters C, D, (having been first oiled or greased) and then charged with the weight of two pounds in the two equal balls G, H, it will require an additional weight x (equal to about a third part of the two pounds) to give motion to, or overcome the friction of the said cylinder.

Now this additional weight, as it causes a greater pressure of the cylinder, will likewise encrease the friction, and therefore require the addition of another weight y , equal to the third part of its own; for the same reason the weight y will require another z , a third part less; and so on *ad infinitum*. Hence upon supposition that the friction is precisely equal to a third of the weight, the first weight with all the additional ones, viz. $2, \frac{2}{3}, \frac{2}{9}, \frac{2}{27}$, &c. will

be a series of numbers in geometrical progression decreasing. Now the sum of all those terms, except the first (i. e. the sum of all the infinite number of additional weights $x+y+z$, &c.) is found (by a known theorem in arithmetic) to be equal to one pound. So that if the weight of the cylinder be inconsiderable, the way to overcome the friction would be to double the power G, or H, at once.

But though we may at a medium allow about a third part of the weight with which any simple machine is charged for the friction arising from thence, yet this is very precarious and seldom the case; for if ABCD (fig. 3.) be a piece of brass of six ounces, and EFGH be also a plate of brass, and both the surfaces well ground and polished, the weight P, of near two ounces, will be required to draw along the body AC alone; but if AC be loaded with 6, 8, or 10 lb. then a sixth part of the weight will be sufficient to draw it along the plane. If the plane be covered with a linen or woollen cloth, then a third, or half part, and sometimes more, will be requisite to draw it along on the plane.

FRICTION, in medicine, the rubbing a diseased part, either with or without unguents, oils, &c. Dr. Cheyne greatly recommends friction with a flesh-brush to persons of weak nerves and sedentary lives; by which means a full and free perspiration would be promoted, and obstructions removed, to the great relief of many valetudinarians.

FRIEZE, FREEZE, or FRIZE, in architecture, a large flat face, or member, separating the architrave from the cornice, being that part of the entablature between the architrave and cornice.

This member was by the ancients called zoophorus, because it was commonly enriched with the figures of animals. The frieze is supposed to be designed to represent the heads of the transverse beams, which sustain the roof or covering.

In the Tuscan order it is quite plain, but is enriched with triglyphs in the Doric; it is sometimes made arched or swelling in the Ionic: in the Corinthian and Composite it is frequently joined to the architrave by a little sweep, and sometimes to the cornice; and in these richer orders, it is commonly adorned with sculpture, figures, compartments, histories, foliages, festoons, &c.

From the variety of their ornaments, friezes obtain various denominations.

Convex or Pulvinated FRIEZES, such whose profile is a curve, the best proportion of which is when drawn on the base of an equilateral triangle.

In some the swelling is only at top, as in a console; in others at bottom, as in the baluster.

Flourished FRIEZES, such as are enriched with rinds of imaginary foliages, as the Corinthian frieze of the frontpiece of Nero: or with natural leaves, either in clusters or garlands; or continued, as in the Ionic of the gallery of Apollo in the Louvre.

Historical FRIEZE, such as are adorned with bas-relievs, representing history, sacrifices, &c. as the arch of Titus at Rome.

Marine FRIEZES, such as represent sea-horses, tritons, and other attributes of the sea, as shells, baths, grottos, &c.

Rustic FRIEZES, such whose courses are rusticated or embossed, as in the Tuscan frieze of Paladio.

Symbolical FRIEZES, those adorned with the attributes of religion, as the Corinthian of the temple behind the capitol at Rome, whereon are represented the instruments and apparatus of sacrifice.

FRIGATE, in the marine, a light nimble ship, built for quick sailing: frigates carry from twenty to thirty-eight cannon, and are esteemed excellent cruifers.

Formerly the name of frigate was only known in the Mediterranean, and given to a kind of long vessel, which they made use of in those seas, and went with sails and oars. The English were the first who appeared on the ocean with those ships; and fitted them for action as well as sailing.

FRIGID, is applied to a jejune stile, that is unanimated by any ornaments, and consequently without any force or vigour.

FRIGID ZONE, in geography. See the article **ZONE**.

FRIGORIFIC, in physiology, small particles of matter, which, according to Gassendus and others, being actually and essentially cold, and penetrating other bodies, produce in them that quality which we call cold. See **COLD**.

FRIST, in the mercantile style, signifies selling goods upon credit, or trust.

FRIT, in the glass manufacture, the matter or ingredients of which glass is to be made, when they have been calcined or baked in a furnace; or it is the calcined matter to be run into glass. See **GLASS**.

There are three kinds of frit; the first, that made for crystal; the second, or ordinary frit, is that made for the common white or crystalline metal; and the third, that made for green glass.

The frit for crystal is made as follows: take two hundred pounds of tarso, powdered fine, and sifted; of the salt of polverine, one hundred and thirty pounds; mix them well together, and put them in the calcar, a sort of oven, or reverberatory furnace, which should first be well heated: here let them remain, baking, frying, and calcining, for five hours, during which, the workman keeps mixing them with a rake, to make them incorporate.

The second, or ordinary frit, is made of bare ashes of polverine, without extracting the salt from them.

The third, for green glass, is made of common ashes, without any preparation.

It may be observed, that glass might be made by immediately melting the materials, without this cal-

cining and making them into frit; but the operation would be much more tedious.

FRIZING of Cloth, a term in the woollen manufacture, applied to the forming of the nap of a cloth, or stuff, into a number of little hard burrs or prominences, covering almost the whole ground thereof.

Some cloths are only frized on the back-side, as black cloths; others on the right-side, as coloured and mixed cloths, rateens, baize, freezes, &c.

FROG, *Rana*, in zoology, a genus of amphibious animals, the body of which is broad and short, without a tail, and furnished with four legs.

FROG, among farriers, the same with frush. See **FRUSH**.

FRONDES, among botanists, denote leaves consisting of several other leaves, and forming the whole of the plant; as is the case of the fern-kind, in which, the fructification being on the back of the leaves, the single leaf makes the whole plant, and is called frondis, not folium.

FRONT of a Battalion, among military men, is the first rank, or file-leaders. It is likewise called the face or head of a battalion.

FRONT of a Place, or the **TENAILLE**, in fortification, all that is contained between the flanked angles of the two neighbouring bastions, viz. the two faces, two flanks, and the curtain.

FRONT, in architecture, the principal face or side of a building, or that which is presented to the chief aspect or view.

FRONT, in perspective, a projection or representation of the face or forepart of an object, or of that part directly opposite to the eye, which is more usually called the orthography. See **ORTHOGRAPHY**.

FRONTAL, in architecture, a little fronton, or pediment, sometimes placed over a little door, or window.

FRONTAL, or **FRONTLET**, or **BROW-BAND**, is also used in speaking of the Jewish ceremonies.

This frontal consists of four several pieces of vellum, on each whereof is written some text of Scripture: they are all laid on a piece of calf's leather, with thongs to tie it by.

The Jews apply the leather with the vellum on their foreheads in the synagoge, and tie it round the head with the thongs.

FRONTALE, in medicine, a name for any external medicine, or topic, applied to the forehead: more particularly it means a refrigerating and hypnotic remedy, prepared of cold cephalics, bruised and tied up in a linen bag, four or five fingers breadth.

FRONTATED, a term used by botanists relating to the leaf of a flower, which grows broader and broader, perhaps terminating in a right-line: and is used in opposition to cuspidated, that is, when the leaves of the flower end in a point.

FRONTIER, the border, confine, or extremity of

of a kingdom or province, which the enemies find in front, when they would enter the same: thus we say, a frontier town, a frontier province, &c. Frontiers were anciently called marches.

FRONTIS OS, in anatomy, called also *os coronale*, the bone of the forehead.

This is a bone of the cranium, of an irregular form, double in infants, but in adults usually single: sometimes, however, it is divided in these into two parts down to the nose. It is situated in the anterior part of the skull, and forms that part of the face which is called the forehead, from whence it has its name. Its figure is symmetrical, resembling a large shell, almost round. See the article **SKULL**.

FRONTISPIECE, in architecture, the portrait or principal face of a building. See **BUILDING**.

FRONTISPIECE is also used to signify an ornament fronting the title page of a book, which, in some measure, should express the subject treated of.

FRONTON, in architecture, the same with pediment. See the article **PEDIMENT**.

FROST, in physiology, such an excessively cold state of the air, as converts watery fluids into ice. See the articles **FREEZING** and **ICE**.

FROTH, a white light substance, formed on the surface of fluids, by vehement agitation; consisting of little sphericles, or globules.

FROTH-SPITTLE, or **CUCKOO-SPITTLE**, a name given to a white froth, or spume, very common in the spring, and first months of the summer, on the leaves of certain plants, particularly on those of the common white field lychnis, or catch-fly, thence called by some spitting poppy.

All writers on vegetables have taken notice of this froth, though few have understood the cause or origin of it till of late; being formed by a little leaping animal, called by some, the flea-grasshopper; by applying its anus close the leaf, and discharging thereon a small drop of a white viscous fluid, which, containing some air in it, is soon elevated into a small bubble; before this is well formed, it deposits such another, and so on, till it is every way overwhelmed with a quantity of these bubbles, which form the white froth which we see.

FRUCTIFEROUS, signifies properly any thing that produces fruit; but, in a more large and figurative sense, it is used by some, particularly lord Bacon, for such experiments in natural philosophy, as prove advantageous to the experimenter in point of gain or profit.

FRUCTIFICATION, among botanists, comprehends both the flower and fruit of plants which cannot be well separated; for though the fruit does not swell and ripen till after the flower is fallen, its rudiment, or first beginning, is in the flower, of which it properly makes a part.

Linnaeus defines the fructification to be a temporary part of vegetables allotted to generation, terminating the old vegetable and beginning the new:

it consists of seven principal parts, viz: 1. the calyx; 2. the corolla; 3. the stamina; 4. the pistillum; 5. the pericarpium; 6. the semina, or seeds; 7. the receptacle. See them explained under their respective articles.

FRUGIVOROUS BIRDS are such as feed on fruits, either wholly or in part.

FRUIT, in general, includes whatever the earth produces for the nourishment and support of man and other animals, as herbs, grain, hay, corn, &c. See the articles **HERB**, **GRAIN**, &c.

FRUIT more properly signifies the production of a tree or plant for the propagation or multiplication of its kinds; in which sense the word includes all kinds of seeds with their furniture; but botanists usually understand by it that part of a plant wherein the seeds are contained.

The fruit of plants is the product or result of a flower, or that for whose production, nutrition, &c. the flower was intended, and in all plants the essential parts of the fruit appear to be only continuations or expansions of those which are seen in the other parts of the tree, and have a communication with the remotest parts, that is, the same fibres which constitute the root, trunk, and boughs, are extended into the fruit itself.

Fruits being known by the different structure or formation of their parts, botanists have therefore applied particular denominations to them, in order to render their description more certain; as the nut, berry, pod, capsule, drupe, pomum, &c. See the articles **NUT**, **BERRY**, &c.

Fruits are serviceable in guarding, preserving, and feeding the inclosed seed; in filtrating the coarser, more earthy, and strong parts, of the nutritious juice of the plant, and retaining it to themselves, sending, none but the most pure, elaborated, and spirituous parts to the seed, for the support and growth of the tender, delicate embryo, or plantule therein contained.

The use of fruits might be rendered much more extensive than it is: many fruits which do hurt when eaten raw, would make wines, equal in flavour to many of those now obtained at a great expence from abroad; and lands, which are not fit for bearing corn, might be a proper soil for bearing corn might be a proper soil for trees and shrubs producing such fruits.—Cherries properly managed make an excellent wine; and, as they are replete with juice, are therefore capable of producing large quantities: the musfel-plumb, which grows wild, makes a very agreeable wine of considerable strength, and, by distillation, affords a pleasant brandy. Gooseberry and currant wine, in particular, if kept to a proper age, is little inferior to the very high priced wines which our good friends of France supply us with.

FRUIT TREES. See the articles **PLANTING**, **PRUNING**, **GRAFTING**, &c. and also their respective names.

FRUITERY, a place for the keeping of fruit, a fruit-house, or fruit-loft. A fruitery should be inaccessible to any thing of moisture, and should be, as much as possible, so even to frost.

FRUMENTACEOUS, a term applied, by botanists, to all such plants as have a conformity with wheat, in respect of their fruits, leaves, ears, or the like.

FRUSH, or **FROG**, among farriers, a sort of tender horn which arises in the middle of a horse's sole; and, at some distance from the toe, divides into two branches, running towards the heel, in the form of a fork.

The frush is a part of a horse's foot, the top of which only should be pared, and that every time the foot is pared, otherwise it is apt to corrupt.

FRUSTUM, in mathematics, a part of some solid body separated from the rest.

FRUSTUM, of a pyramid, or cone, is a piece or part thereof cut off, generally by a line parallel to the base. The solidity of the frustum of a square pyramid may be found by the following theorem.

To the rectangle of the sides of the two bases add the sum of their squares; that sum being multiplied into one third of the frustum's height, will give its solidity.

The solidity of the frustum of a cone may be found by the following theorem.

To three times the rectangle of the two diameters add the square of their difference; that sum multiplied by the height will give the solidity.

FRUTICOSE STALKS, among botanists, those with a hard woody substance. See **STALK**.

FUCHSIA, in botany, a genus of plants whose flower consists of a monopetalous funnel-shaped corolla, with four filaments topped with obtuse antheræ; the fruit is a roundish berry, with four furrows and four cells, containing a number of ovated seeds, and placed in a double series.

Of this genus there is but one species hitherto known, which is a native of the warm part of America, therefore requires a hot house in this climate to preserve it.

FUCUS, in botany, a genus of submarine plants belonging to the cryptogamia class of Linnæus.

The fucus consists of a tough matter, formed into a kind of leaves, which have some appearance of fructification, in punctated tubercles, covering oblong vesicles, supposed by Linnæus to be male flowers; and smooth, roundish vesicles, hollow and interwoven with filaments, which appear to him to be female flowers.

There are a great many species of fucus with broader or narrower leaves, and other peculiarities; one of which, the broad-leaved, serrated fucus, grows to the height of six, eight, or more inches.

FUGITIVE, a person obliged to fly his country, or remove from a place where he had some abode, or establishment, on account of his crimes, debts, or other occasions.

FUGUE, in music, is when different parts of a musical composition follow each other, each repeating what the first had performed.

There are three kinds of fugues; the simple, double, and counter.

Single, or *Simple FUGUE*, is some point consisting of four, five, or more notes, begun by one simple part, and seconded by a second, third, fourth, fifth, &c. if the composition consist of so many; repeating the same or such like notes, that is, in the same proportion, so that the several parts follow, or come in one after another, in the same manner; the leading part still flying before those that follow.

FUGUE DOUBLE, or **FUGA DOPPIA**, is when two or more different points move together in a fugue, and are alternately mixed and interchanged by the several parts.

FULCRUM, in mechanics, the prop or support by which a lever is sustained. See the article **LEVER**.

FULICA, the coot, in ornithology, a genus of birds, of the order of the gallinæ, with a naked or bald forehead, and divided or cloven feet: add to this, that all the toes are longer than in whole-footed birds, and have semicircular membranes affixed to their joints.

FULIGINOUS, whatever proceeds from a thick, sooty smoke, such as litharge and lamp-black.

FULL-MOON, *plenilunium*, that phasis of the moon when, in her opposition to the sun, the whole of her disk is illuminated; in which time eclipses of the moon can only happen. See the articles **MOON** and **ECLIPSE**.

FULLER, a workman employed in the woollen manufactories, to mill, or scour, cloths, serges, and other stuffs, in order to render them more thick, compact, and durable. See **CLOTH**.

FULLER'S EARTH, *cimolia purpurascens*, a kind of marle of a close texture, and of a tolerable smooth and glossy surface, when it has been rubbed. It is extremely soft and unctuous to the touch, of a greyish brown colour, with some admixture of the olive or greenish.

The finest fuller's earth in the world is dug in England, and all the nations round us would gladly purchase it at a great price, were the exportation of it allowed; but one of the great advantages of our woollen manufactory is the keeping it at home. Large quantities of it are dug near Woburn in Bedfordshire; there are also pits of it in Surry, and some other counties; and strata in many places, where it would be very well worth the proprietors while to have it dug, though at present it is neglected.

It is of great use in scouring cloths, stuffs, &c. as it imbibes all the oil and greafe used in dressing the wool.

FULLER'S WEED, in botany, a name sometimes given to the dipsacus, or teasel. See **DIPSACUS**.

FULLING, the art or act of scouring and pressing cloths, stuffs, stockings, &c. to cleanse, thicken, and render them more firm and strong, which is done by means of a water-mill.

In the troughs of the mill are laid the cloths, stuffs, &c. intended to be full'd: then letting the current of water fall on the wheel, the mallets are successively let fall upon them, when by their weight and velocity they stamp and press the stuffs very strongly, which by this means becomes thickened and condensed.

In this operation, fullers earth is used with some proportion of sope; but sope alone would do much better, was it not dearer than fuller's earth.

Fulling of stockings, caps, &c. is performed either with the hands or feet, or a kind of wooden machine, either armed with wooden teeth, or those of horses or bullocks. The ingredients generally used on this occasion are fuller's earth, urine, white and green sope; but water softened with chalk is far preferable.

The following is Mr. Colmet's method of fulling with sope, grounded on experiments made by order of the marquis de Louvois. Let a coloured cloth of about forty-five ells, be laid in the usual manner in the trough of a fulling-mill, without first soaking it in water, as commonly practised in most places. To full this trough-full of cloth fifteen pounds of sope are required, one half of which is to be melted into two pails of river or spring water, made as hot as the hand can bear. Let this solution be poured by little and little, upon the cloth, in proportion as it is laid in the trough: thus it is to be full'd for at least two hours; after which, let it be taken out and stretched. This done, let the cloth be immediately returned into the same trough, without fresh sope, and there full'd two hours more: then take it out, wring it well, and express all the greafe and filth. After the second fulling, dissolve the remainder of the sope, as the former part, and throw it at four several times on the cloth, not forgetting to take it out every two hours, to undo the plaits and wrinkles it got in the trough. When it is sufficiently full'd, and brought to a requisite quality and thickness, it is scoured out for good in hot water, keeping it in the trough till it be thoroughly clean. As white cloths full more easily than coloured ones, a third part of the sope may be saved.

FULMINATING, something that thunders, or resembles thunder. See the articles **THUNDER**.

FULMINATION, in chemistry, is used in a synonymous sense with detonation. See **DETONATION**.

FUMIGATION, in chemistry, a kind of calcination, when metals, or other hard bodies, are corroded, or softened, by receiving certain fumes for that purpose.

FUMIGATION, in medicine, the application of fumes to particular parts of the body; as those of factitious cinnabar to venereal ulcers.

FUMARIA, *Fumitory*, in botany, a genus of plants producing oblong tubulated ringent flowers, including two equally broad filaments terminated with three antheræ to each. The fruit is a short unilocular pod, containing a number of roundish seeds.

The common fumitory is a low annual plant, with bluish green leaves finely divided; the flowers are produced on the tops of the stalks in May and June; the leaves are intensely bitter; and are said to open obstructions, to strengthen the stomach and viscera, and to promote urine; it is also reckoned good against melancholy hypochondriac disorders, the jaundice, and scurvy; and Hoffman gives it the preference to all other herbs as a purifier of the blood.

FUNCTION, the act of fulfilling the duties of any employment.

Function is also applied to the actions of the body.

FUNCTION, in algebra, denotes any compound quantity; and when one of the component quantities is variable, it is said to be a variable function. See the article **QUANTITY**.

FUND, in anatomy, signifies the bottom of any cavity in the body, thus, the fund of the eye is that part possessed by the choroides and retina; the fund of the uterus, the fund of the bladder, &c. signify also the bottom of these parts. See the articles **EYE** and **UTERUS**.

FUND, in commerce, signifies the stocks of the great trading and monied companies. See the article **STOCKS**.

FUNDS is also a term adopted by those who speak of the public revenue of nations, to signify the several taxes that have been laid upon merchandizes either by way of duties of custom, or extise, or in any other manner, to supply the exigencies of the state, and to pay interest for what sums it may have occasion to borrow.

FUNERAL RITES, ceremonies accompanying the interment or burial of any person. See the article **BURIAL**.

FUNERAL COLUMN, a column crowned with an urn, wherein the ashes of some deceased person are supposed to be inclosed; the fust or shaft being beset with tears or flames, the symbols of grief and immortality. See **COLUMN**.

FUNGUS, in surgery, a soft, fleshy, spongy excrescence, arising in the membranes, tendons, and other nervous parts, in consequence of ulcers, wounds, contusions, &c.

To the order of fungi belong several genera; as, agaric, phallus, cycoperdon, &c. See AGARIC.

FUNNEL of a Chimney, the shaft or smallest part of the waste, where it is gathered into its least dimensions.

Palladio directs, that the funnels of chimnies be carried through the roof four or five feet at least, that they may carry the smoke clear from the house into the air. See CHIMNEY.

He also advises, that chamber-chimneys be not made narrower than ten or eleven inches, nor broader than fifteen; for if too narrow, the smoke will not be able to make its way; and if too wide, the wind will drive it back into the room.

FUNNEL-FASHIONED, or **FUNNEL-SHAPED FLOWERS**, in botany. See the article INFUNDIBULIFORM.

FUR, or **FURR**, in commerce. See FURR.

FURBISHER, a person who furbishes, polishes, or cleans arms, as guns, swords, pistols, &c. which is chiefly performed with emery.

FURIES, *Eumenides*, *Diræ*, certain goddesses, whose office it was to punish the guilty after death. These were three in number, Alecto, Megæra, and Tisiphone, who were described with snakes instead of hair, and eyes like lightning, carrying iron chains and whips in one hand, and in the other flaming torches; the latter to discover, and the former to punish the guilty; and they were supposed to be constantly hovering over such persons as had been guilty of any enormous crime.

Mythologists suppose, that Tisiphone punished the crimes which sprang from hatred or anger; Megæra, those from envy; and Alecto, those from an insatiable pursuit after riches and pleasure. They were worshipped at Calina in Arcadia, and at Carmia in Peloponnesus. They had a temple at Athens, near the Areopagus, and their priests were chosen from amongst the judges of that court. At Telphus, a city in Arcadia, a black ewe was sacrificed to them.

FURLING, in the sea language, rolling a sail up close to the yard, stay, or mast, and fastening it by rolling a bandage or rope close about it; and hence,

FURLING-LINE is a line to fasten the sail; those which are made for yards are plaited and flat, and called gasketts.

FURLONG, a long measure, equal to $\frac{1}{8}$ of a mile, or forty poles. See the articles MEASURE, MILE, and POLE.

It is also used in some law-books for the eighth part of an acre. See ACRE.

FURLOUGH, in the military language, a licence granted by an officer to a soldier, to be absent for some time from his duty.

FURNACE, a vessel or utensil for maintaining a strong fire, either of coal or wood.

FURNACE is also applied to that used in the melting of iron, which authors frequently confound with iron forges, though there is a considerable difference between them. See FORGE.

FURNITURE, in dialling, certain additional points and lines, such as the ecliptic, circles of declination, azimuths, Italian hours, points of the compass, &c. drawn on dial-planes.

FUROR UTERINUS, a species of madness peculiar to women, proceeding from an ardent and inordinate desire of coition, which deprives the patient of the use of reason, so that he speaks all manner of obscene words, and, abandoning all shame, invites the men to venereal embraces.

The immoderate desire of copulation is produced by the plenty, acrimony, and heat of the uterine juices, exceeding the natural bounds, and creating an extraordinary turgency in the femoral vessels, which, stimulating in a manner and inflaming the genital parts, excites a vehement and unruly appetite to venereal commerce.

FURR, in commerce, signifies the skin of several wild beasts, dressed in alum with the hair on, and used as a part of dress by princes, magistrates, and others. The kinds most in use are those of the ermine, sable, castor, hare, rabbit, &c. See the articles ERMINE, SABLE, &c.

FURRS, in heraldry, a bearing which represents the skins of certain beasts, used as well in the doublings of the mantles belonging to the coat-armour, as in the coat-armours themselves. See ERMINE.

FURR, among carpenters, a piece nailed upon a rafter, to strengthen it when decayed, or to make it straight when it has sunk in the middle.

FURRING, among carpenters, is the regular fashioning out any part. When the main piece of the material is scanty, either by defects, wains, or want of thickness; then a piece of the same is put behind it to make good its thickness, which is called a furr.

FURUNCLE, or **BOIL**, in surgery, a small resisting tumour, with inflammation, redness, and great pain, arising in the adipose membrane, under the skin.

As there is no part of the body free from being the subject of furuncles, so the whole is sometimes so miserably infested with them, that the patient can hardly tell how to stir himself, or on what part to lie. Not only adults, but also the younger, even newborn infants, are obnoxious to this dreadful disorder, which occasions in them most fatiguing clamour and restlessness. Though there is little danger in this disease in adults, yet, in tender infants, it occasions convulsions, and even death itself.

The principal cause of furuncles is a too glutinous and inspissated state of the blood; and, consequently, the greater the inspissation, the worse and more numerous will be the furuncles.

With

With regard to the cure, it seems to consist chiefly in restoring the stagnated blood to its former circulation and free motion.

When the furuncles are very numerous, or return again, it is proper to use internal purging medicines, and such as attenuate and cleanse the blood. In adults, bleeding is proper, both by the lancet and scarification with cupping; and, at the same time, a strict regimen of diet should be used, drinking frequently and plentifully of a decoction of the woods, and such like attenuators of the blood. The patient should also entirely abstain from drinking fermented and spirituous liquors, particularly wine and its spirit; and from the too frequent use of tobacco. When the disorder is recent, external medicines only will frequently suffice for the whole cure. For this purpose, a mixture of honey, acidulated with spirit of vitriol till it has acquired a considerable sharpness, is proper to anoint the furuncles. Of no less virtue is the frequent touching them with mere spirit of vitriol or sulphur. Discutient plasters are also found very serviceable, as those of simple diachylon, de melito, de sfermaceti, vel diasaponis.

But if these medicines prove insufficient to disperse the tumour, it is to be brought to suppuration, by applying a plaster made of honey and flour, or of diachylon with the gums; and where these are insufficient, to make use of the maturing cataplasms recommended under the article PHLEGMON.

When the furuncle is known to be ripe, by its softness and yellow head, recourse is to be directly had to the scalpel; and having made an opening, the corrupted matter contained therein is to be discharged: after this, a plaster of diachylon must be applied, and the ulcer daily cleansed of its matter, till it is healed.

Pustules and pimples arising in the face, are to be treated like furuncles; and, in both cases, the drinking of whey, and the mineral waters, is accounted good for cleansing the blood.

When sucking infants are afflicted with furuncles, it is proper to give the mother, or nurse, some purging medicine, and to order a strict regimen and diet. At the same time, the infant should take some gentle laxative medicine, with absorbent powders, to allay the acrimony of its juices. *Heister.*

FURZE, or FURZE-BUSH, in botany. See the article ULEX.

FUSAROLE, in architecture, a round member, carved in the manner of a collar or chaplet, with oval beads, and placed immediately under the echinus, in the Doric, Ionic, and Composite capitals.

FUSEE, in clock work, is that conical part drawn by the spring, and about which the chain or string is wound; for the use of which, see the articles CLOCK and WATCH.

FUSEE, or FIRELOCK. See MUSKETT.

FUSIBILITY, in natural philosophy, that quality of bodies which renders them fusible.

FUSIL, in heraldry, a bearing of a rhomboidal figure, longer than the lozenge, and having its upper and lower angles more acute and sharp than the other two in the middle.

It is called in Latin, *fusus*, a spindle, from its shape.

FUSILIERS, or FUSILEERS, in the military art, are foot soldiers, armed with fuses, or firelocks. See the article FIRELOCK.

FUSILY, or FUSILE, in heraldry, signifies a field, or ordinary, entirely covered over with, or divided into, fusils. See FUSIL.

FUSION, the melting of metals, minerals, &c. by means of fire.

Different metals run in different manners from their ores: thus, lead, though extremely fusible in the metal, runs with difficulty from the ore, so as to require a considerable violence of fire. This stubbornness not belonging to the metal, must be attributed to the stony, sulphureous, or other mineral matter with which the ore is mixed; which matter seems to require a degree of heat capable of vitrifying the lead, before the metal will run: but then the lead thus vitrified, recovers a metallic form again, by coming in contact with the coals. See the article LEAD.

Tin runs from its ore with greater ease than lead, and is therefore melted in much less furnaces: but copper requires an intense heat, or a blast furnace; and iron the greatest heat that can be given in a furnace: and both iron and copper absolutely require immediate contact with the fuel employed. Hence it appears, that each metal must have its determinate degree of heat, to run it with advantage from the ore or stone.

In order, likewise, to obtain the metal from the ore to the best advantage, the scoria or slag must be necessarily made to run thin and fluid; otherwise it entangles or inviscates the metal, and will not let it separate fully. And hence we may frequently observe, in the assaying of copper ores, small grains of metal interpersed here and there, among the scoria, that require to be separated by stamping and washing the whole mass; which labour might have been prevented, by using a proper degree of heat capable of procuring a thin fusion and a suitable flux, so as to have made all the metals fall to the bottom of the crucible; which it constantly does, when the operation is well performed. See FLUX.

It seems principally owing to a defect in the knowledge of fusion, that so many recrements or slags of metals, anciently thrown as useless from the furnace, have been of late wrought to considerable profit by more skilful workmen: at least, it seems more rational to attribute the success to this cause, than to a supposed growth of metals in such slags; or to believe

lieve that lead has grown rich in silver by lying exposed to the open air, while, perhaps, it is rather owing to the unskilfulness of the former workmen, who were unable to separate all the silver contained in the lead.

All moisture, and too sudden cooling, prove prejudicial to the more ignoble metals after fusion, and sometimes dangerous to the operator: for a little water falling upon melted iron or copper, makes them expand with prodigious violence, and discharge themselves abroad with a force like that of a cannon; and even sudden cooling will often occasion the surface of the metal to crack, and suffer the more internal part, not yet set or fixed, to issue out to a considerable distance; whence either the loss of the metal or mischief may ensue.

To prevent these ill effects, after copellation it is usual for the operator to throw a quantity of water, all at once, upon the lump of silver, as it lies in the test, at the moment when it begins to grow rigid; for the water, by its coldness, suddenly makes so thick a cover upon the surface of the silver, that the hotter parts in the inside cannot break through the upper. *Shaw's Chem. Lect.*

FUST, the same with the shaft of a column. See the articles **COLUMN** and **SHAFT**.

FUSTIAN, in commerce, a kind of cotton stuff, which seems as it were whaled on one side.

Right fustians should be altogether made of

cotton-yarn, both woof and warp; but a great many are made, of which the warp is flax, or even hemp.

There are fustians made of several kinds, wide, narrow, fine, coarse; with shag, or nap, and without it.

FUSTIC, the wood of a species of mulberry, which grows naturally in the West-Indian islands and Campeachy. With us it is much used for dyeing yellow.

FUTTOCKS, in ship-building, that part of a timber which reaches from the floor to the top-timber. See this distinctly explained in the article **TIMBER**.

FUTTOCK-Shrowds. See the article **Futtock-Shrowds**.

FUTURE, in general, denotes whatever regards futurity, or the time to come. See the article **TIME**.

FUTURE TENSE, among grammarians. See the article **TENSE**.

FUZEE, or **FUSEE**, in military affairs. See the article **FUSEE**.

FUZEE, among farriers, two dangerous splents, joining from above downwards. They differ from screws or thorough splents in this, that the latter are placed on two opposite sides of the leg. See the article **SELENT**.

G A B

G, in grammar, the seventh letter and fifth consonant of our alphabet; but in the Greek, and all the oriental languages, it occupies the third place. It is one of the mutes, and cannot be sounded without the assistance of some vowel.

In English it has a hard and soft sound; hard, as in the words *game*, *gun*, &c. and soft, as in the words *gesture*, *giant*, &c. at the end of words, *gh* is pronounced like *ff*, as in the words *rough*, *tough*, &c. The letter *g* is also used in many words where the sound is not perceived, as in *sign*, *reign*, &c.

As a numeral, *G* was anciently used to denote 400; and with a dash over it, thus $\overline{G}$, 40,000. In music it is the character or mark of the treble cleff; and from its being placed at the head, or marking the first sound in Guido's scale, the whole scale took the name gamut. See the articles *CLEF* and *GAMUT*.

GABEL, a word met with in old records, signifying a tax, rent, custom, or service, paid to the king, or other lord.

GABEL, according to the French duties or customs, a tax upon salt, which makes the second article in the king's revenue, and amounts to about one fourth part of the whole revenue of the kingdom.

GABIONS, in fortification, baskets made of osier-twigs, of a cylindrical form, six feet high, and four wide; which being filled with earth, serve as a shelter from the enemies fire.

They are commonly used on batteries, to screen the engineers, &c. in order to which, one is placed on either side of each gun, room being only left for the muzzle to appear through. They also serve as a parapet on lines, lodgments, &c. when the ground is too hard to dig into.

There are a smaller sort, used on parapets in trenches, &c. to cover the musqueteers; which are placed so close that the muzzle of a musquet can hardly be put through.

GABLE, or **GAVEL**, among builders. See **GAVEL**.

G A G

GAD, among miners, a small punch of iron, with a long wooden handle, used to break up the ore.

One of the miners holds this in his hand, directing the point to a proper place, while the other drives it into the vein, by striking it with a sledge hammer.

GAD-FLY, or **BREEZE-FLY**, names given to the black and yellow bodied cestrus, a fly nearly as large as the common blue flesh-fly. See *Oestrus*.

GAFOld-LANd, in old law-books, land liable to taxes, and let for rent.

GAGATES, *JET*, in natural history. See the article *JET*.

GAGE, in law-books, the same with surety or pledge. See the articles *SURETY* and *PLEDGE*.

GAGE, in joinery, an instrument in which a piece of wood is moveable upon a staff, so as to be set nearer or farther at pleasure. Its use is to draw a line parallel to the straight side of any board, for gaging tenons, and marking stuff for an equal thickness.

GAGE, among letter-founders, a piece of box, or other hard wood, variously notched; the use of which is to adjust the dimensions, slopes, &c. of the different sorts of letters. See *Letter Foundry*.

Sliding-GAGE, a tool used by mathematical instrument makers, for measuring and setting off distances.

GAGE, or **Weather-GAGE**, in navigation, a ship is said to have gained the weather-gage of another when she makes a greater progress to the windward, or when she sails to the windward of some other. See the article *TACKLING*.

Sea-GAGE, an instrument invented by Dr. Hales and Dr. Desaguliers, for finding the depth of the sea.

Bucket-Sea-GAGE, an instrument contrived by Dr. Hales, to find the different degrees of coldness and saltness of the sea, at different depths; consisting of a common household pail or bucket, with two heads

heads to it. These heads have each a round hole in the middle, near four inches diameter, and covered with valves opening upwards; and that they might both open and shut together, there is a small iron rod fixed to the upper part of the lower valve, and at the other end to the under part of the upper valve; so that as the bucket descends with its sinking weight into the sea, both the valves open by the force of the water, which by that means has a free passage through the bucket. But when the bucket is drawn up, then both the valves shut by the force of the water at the upper part of the bucket; so that the bucket is brought up full of the lowest sea-water to which it had descended.

When the bucket is drawn up, the mercurial thermometer, fixed in it, is examined; but great care must be taken to observe the degree at which the mercury stands, before the lower part of the thermometer is taken out of the water in the bucket, else it would be altered by the different temperature of the air.

In order to keep the bucket in a right position, there are four cords fixed to it, reaching about four feet below it, to which the sinking weight is fixed.

Water-GAGE, or HYDROMETER. See the article *HYDROMETER*.

GAIANITES, Gaianita, in church history, a branch of Eutychians. See *EUTYCHIAN*.

GAIN, in commerce, is used in a synonymous sense with profit. See *PROFIT*.

GAIN, in architecture, the levelling shoulder of a joist or other timber.

It is also used for the lapping of the end of the joints, &c. upon a trimmer or girder, and then the thickness of the shoulder is cut into the trimmer, also levelling upwards, that it may just receive the gain, and so the joist and trimmer lie even and level with the surface.

This way of working is used in floors and hearths.

GALANGALS, Galanga, in the materia medica, the name of two roots kept in the shops, a greater and a smaller; of which the smaller is by far the most esteemed.

The lesser galangal is a small and short root, of an irregular figure, and of the thickness of a man's little finger, seldom met with more than an inch or two long. It should be chosen full and plump, of a bright colour, very firm and sound, and of an acrid and insupportably hot taste.

The larger galangal is brought to us in pieces of two inches or a little more in length, and of near an inch in thickness: its surface is less unequal and tuberoso than the smaller sort, but is far from being smooth; on the outside it is of a brown colour, with a very faint cast of red, and within it is of a paler colour, and has a much less acrid and pungent

taste than the smaller kind. It is to be chosen in the largest, foundest, and heaviest pieces.

The roots of both the galangals, but particularly of the lesser, abound with a volatile, oily, aromatic salt; the lesser is esteemed an excellent stomachic: it has the credit of being a great cephalic, cardiac, and uterine, but is more particularly recommended in vertigos. The greater galangal possesses the same virtues, but in a less degree.

GALANTHUS, the snow-drop, in botany, a bulbous rooted plant, whose flower consists of three oblong concave petals, which spread open and are equal; the nectarium is obtuse, cylindrical, and indented; the stamina are six short filaments, topped with oblong acuminate anthers, inclining together; and the fruit is an oval capsule obtusely trigonal, with three cells, which are filled with a number of roundish seeds. The snow-drop being one of the first flowers which blow in the spring, it therefore well deserves a place in gardens, particularly a variety with a double nectarium.

GALAXY, in astronomy, the via lactea, or milky way in the heavens: a tract of a whitish colour, and considerable breadth, which runs through a great compass of the heavens, sometimes in a double, but for the greatest part of its course in a single stream; and is composed of a vast number of stars, too minute or too remote from the earth to be distinguished by the naked eye; but are discovered in all parts of it, in great numbers, by the assistance of the telescope.

GALBANUM, in pharmacy, a gum issuing from the stem of an umbelliferous plant, growing in Persia and many parts of Africa.

It is sometimes met with in the shops in loose granules, called drops or tears, and sometimes in large masses, formed of a number of these blended together; but in these masses some accidental foulness is often mixed with the gum. The single drops usually approach to a roundish, oblong, pear-like form. Galbanum is soft like wax, and, when fresh drawn, white; but it afterwards becomes yellowish or reddish: it is of a strong smell, of an acrid and bitterish taste; it is inflammable in the manner of a resin, and soluble in water like a gum.

It attenuates and dissolves tough phlegm, and is therefore of service in asthmas and inveterate coughs: it is also of great service in hystERIC complaints; it dissipates flatulencies, promotes the menses, and facilitates delivery and the expulsion of the secundines. It is given in pills and electuaries, and is used externally in form of a plaster, applied to the belly, against habitual hystERIC complaints, and on many other occasions.

GALENIC, or GALENICAL, in pharmacy, a manner of treating diseases founded on the principles of Galen.

The distinction of galenical and chemical was occasioned

eaſioned by a diviſion of the practitioners of medicine into two ſects, which happened on the introduction of cheſmiftry into medicine; then the cheſmifts arrogating to themſelves every kind of merit and ability, ſtirred up an oppoſition to their pretenſions, founded on the invariable adherence of the other party to the ancient practice. And though this diviſion into the two ſects of galeniſts and cheſmifts has long ceaſed, yet the diſtinction of medicines, which reſulted from it, is ſtill retained.

Galenical medicines are thoſe which are formed by the eaſier preparations of herbs, roots, &c. by infuſion, decoction, &c. and by combining and multiplying ingredients; while thoſe of cheſmiftry draw their more intimate and remote virtues by means of fire and elaborate preparations, as calcination, diſteſtion, fermentation, &c.

GALENISTS, in church hiſtory, a branch of anabaptiſts, who are ſaid to have adopted ſeveral Arian opinions concerning the divinity of our Saviour.

GALILEANS, a ſect of Jews. Their founder was one Judas, a native of Galilee, from which place they derived their name. Their chief, eſteeming an indignity for the Jews to pay tribute to ſtrangers, raiſed up his countrymen againſt the edict of the emperor Auguſtus, which had ordered a taxation or enrollment of all the ſubjects of the Roman empire.

They pretended that God alone ſhould be owned as Maſter and Lord; and in other reſpects were of the opinion of the Pharifees: but as they judged it unlawful to pray for infidel princes, they ſeparated themſelves from the reſt of the Jews, and performed their ſacrifices apart.

GALL, in the animal œconomy, the ſame with bile. See BILE and BILIOUS.

GALL-BLADDER, called *veſicula*, and *cyſtis fellea*, is uſually of the ſhape of a pear, and of the ſize of a ſmall hen's egg. It is ſituated in the concave ſide of the liver, and lies upon the colon, part of which it tinges with its own colour. It is compoſed of four membranes, or coats; the common coat, a veſicular one, a muſcular one (conſiſting of ſtraight, oblique, and tranſverſe fibres) and a nervous one, of a wrinkled or reticulated ſurface within, and ſurrounded with an unctuous liquor.

The uſe of the gall-bladder is to collect the bile, firſt ſecrated in the liver, and mixing it with its own peculiar produce, to perfect it farther, to retain it together a certain time, and then to expel it.

GALL, in natural hiſtory, denotes any protuberance or tumour produced by the puncture of infects on plants and trees of different kinds.

Theſe galls are of various forms and ſizes, and no leſs different with regard to their internal ſtructure. Some have only one cavity, and others a number of ſmall cells communicating with each other. Some of them are as hard as the wood of the tree they

grow on, whiſt others are ſoft and ſpongy; the firſt being called gall-nuts, and the latter berry-galls, or apple-galls.

The general hiſtory of galls is this: an infect of the fly-kind is inſtricted by nature to take care for the ſafety of her young, by lodging her eggs in a woody ſubſtance, where they will be defended from all injuries: ſhe, for this purpoſe, wounds the branches of a tree; and the lacerated veſſels, diſcharging their contents, ſoon form tumours about the holes thus made. The hole in each of theſe tumours, through which the fly has made its way, may for the moſt part be found; and when it is not, the maggot-inhabitant or its remains are ſure to be found within, on breaking the gall. However, it is to be obſerved, that in thoſe galls which contain ſeveral cells, there may be infects found in ſome of them, though there be a hole by which the inhabitant of another cell has eſcaped.

Oak-galls put, in a very ſmall quantity, into a ſolution of vitriol in water, though but a very weak one, give it a purple or violet colour; which, as it grows ſtronger, becomes black; and on this property depends the art of making our writing-ink, as alſo a great deal of thoſe of dyeing and dreſſing leather, and other manufactures.

In medicine, galls are found to be very aſtringent, and good, under proper management, in diarrheas, dysenteries, and hæmorrhages of all kinds; they have alſo a very eminent virtue as a febrifuge. Half a dram, or more, of the powder of Aleppo galls, may be given for a doſe, and will often cure an intermittent fever. They are alſo uſed externally by way of fomentation in prociſtentia of the anus: and a decoction of them has been injected in the fluor albus with great ſucceſs.

GALLEASSES, in the marine, the largeſt ſort of armed veſſels next to ſhips of war: they are a ſort of ſhip of one deck and three maſts; and are uſed by the Venetians only: they have thirty-two banks of oars, with ſix or ſeven ſlaves to an oar; three batteries of guns from thirty-fix to twenty-four pounders; their complement of men conſiſts of a thouſand or twelve hundred. To ſee one of theſe galleaſſes at ſea, ſhe appears like a great floating iſland, able in appearance to encounter with twenty galleons (ſee the next article). The Turks have ſhips not unlike them, which they call mahones.

GALLEON was formerly a name given to ſhips of war which had three or four decks. The name is now no longer in uſe but with the Spaniards, which they give to their ſhips which are deſtined for Weſt-India voyages. Theſe ſhips, which are of a larger ſize, have always four decks. They give alſo the ſame name to greater or ſmaller veſſels, which go yearly to La Vera Cruz. The Portuguese have ſhips which they call caragues, ſomewhat reſembling the galleon, which they ſend to India and the Brazils.

GALLERY of a *Ship*, a sort of raised balcony, without the cabin, at the stern or quarter of a ship, for the convenience of the commander.

GALLERY, in architecture, a covered place in a house, much longer than broad, and usually in the wings of a building, its use being chiefly to walk in.

GALLERY, in fortification, a covered walk across the ditch of a town, made of strong beams, covered over head with planks, and loaded with earth: sometimes it is covered with raw hides, to defend it from the artificial fires of the besieged. Its sides should be musket proof. It ought to be eight feet high, and ten or twelve wide, and the covering to rise with a ridge, that what is thrown upon it by the besiegers with a design to burn it, may roll off.

Galleries are chiefly used to secure and facilitate the miners approach to the face of the bastion, over the moat, which is already supposed to be filled up with faggots and bavins, and the artillery of the opposite flank dismounted.

GALLERY of a Mine, is a narrow passage, or branch of a mine, carried on underground to a work designed to be blown up.

Both the besiegers and the besieged also, carry on galleries in search of each other's mines, and these sometimes meet and destroy each other.

GALLERY, in gardening, a kind of covered walk in a garden, formed into porticoes or arches, with trees of different sorts; but in the present practice is much in disuse.

GALLEY, a kind of low flat-built vessel, with one deck, made either to sail or row: they are from an hundred and twenty, to an hundred and thirty feet long, eighteen feet broad, and nine or ten feet deep. They have two masts which can be struck at pleasure, two lateen sails, and five pieces of cannon. The galleys have commonly twenty-five or thirty banks of oars on either side, to each of which are chained five or six slaves. There are no gallies now but in the Mediterranean: they commonly keep close along shore, though they sometimes venture out to sea for a short cruise.

GALLIAMBIC VERSE, *Galliambus*, in ancient poetry, a verse consisting of six feet, viz. an anapest, or a spondee; an iambus, or an anapest, or a tribrach; an iambus; a dactyl; a dactyl; an anapest.

The word galliambus is a compound of iambus and gallus, a priest of Cybele. These priests carried about the image of that goddess, in order to get alms, and as a part of their employment was singing verses all over the country, they, by this means, rendered poetry very despicable.

GALLI, in antiquity, the priests of the goddess Cybele, who were eunuchs, and took their name from Gallus, a river in Phrygia.

GALLICAN, any thing belonging to France: thus the term Gallican-church, denotes the church

of France, or the assembly of the clergy of that kingdom. See **CHURCH**.

GALLINÆ, in ornithology, an order of birds, the beak of which is conic, and somewhat incurvated, and the upper chap imbricated.

Under this order are comprehended the ostrich, peacock, pheasant, woodcock, turkey, the common dunghill-cock, partridge, &c.

GALLINACEOUS, an appellation given to birds of the order of the gallinæ.

GALLING, or **EXCORIATION**, in medicine. See **EXCORIATION**.

GALLING of a Horse's Back, a disorder occasioned by heat, and the chafing or pinching of the saddle.

In order to prevent it, some take a hind's skin well garnished with hair, and fit it neatly under the pannel of the saddle, so that the hairy side may be next the horse.

When a horse's back is galled upon a journey, take out a little of the stuffing of the pannel over the swelling, and sew a piece of soft white leather on the inside of the pannel; anoint the part with salt butter, and every evening wipe it clean, rubbing it till it grow soft, anointing it again with butter, or, for want of that, with grease: wash the swelling, or hurt, every evening with cold water and soap, and strew it with salt, which should be left on till the horse be saddled in the morning.

GALLIUM, ladies-bedstraw, in botany, a genus of plants, the flower of which is a quadrifid single petal, without any tube, and placed flatwise: the fruit consists of two globose bodies, growing close together, but not adhering, and containing each a single kidney-shaped seed. It is said to be an excellent astrigent.

GALLON, a measure of capacity both for dry and liquid things, containing four quarts; but these quarts, and consequently the gallon itself, are different, according to the quality of the thing measured: for instance, the wine gallon contains 231 cubic inches, and holds eight pounds averdupois of pure water: the beer and ale gallon contain 282 solid inches, and holds ten pounds three ounces and a quarter averdupois of water; and the gallon for corn, meal, &c. 272½ cubic inches, and holds nine pounds thirteen ounces of pure water.

GALLOON, in commerce, a narrow thick kind of ferret, or lace, used to edge or border cloaths, sometimes made of wool, and at others of gold or silver.

GALLOP, in the manege, a motion of a horse that runs at full speed; in which, making a kind of leap forwards, he lifts both his fore-legs almost at the same time; when these are in the air, just upon the point of touching the ground, he lifts both his hind-legs almost at once.

GALLOWs of a Plough, a part of the plough head,

head, so called by farmers, from its resemblance to the common gallows, as consisting of three pieces of timber, whereof one is placed transversely over the heads of the other two. See *PLOUGH*.

GALLUS, the *Cock*, in ornithology, a well known domestic fowl, the head of which is ornamented with a longitudinal fleshy crest, or comb: the wattles are two, and placed longitudinally on the throat. This, in its natural state, is a very robust and beautiful bird, variegated with a great number of elegant colours.

GALLY, in printing, a frame into which the compositor empties the lines out of his composing-stick, and in which he ties up the page when it is completed.

The gally is formed of an oblong square board, with a ledge on three sides, and a groove to admit a false bottom, called a gally-slice.

GAMBOGE, is a concreted vegetable juice, the produce of two trees, both called by the Indians *caracapulli*, and is partly of a gummy, and partly of a resinous nature. It is brought to us either in form of orbicular masses, or of cylindrical rolls of various sizes; and is of a dense, compact, and firm texture, and of a beautiful yellow. It is chiefly brought to us from Cambaja, in the East-Indies, called also *Cambodja*, and *Cambogia*; and from thence it has obtained its names of *cambadium*, *cambogium*, and *gambogium*.

It is a very rough and strong purge; it operates both by vomit and stool, and both ways with much violence, almost in the instant in which it is swallowed; but yet without griping. It requires caution and judgment in administering it; but those who know how to give it properly, find it an excellent remedy in dropsies, cachexies, jaundice, asthma, catarrhs, and in the worst cutaneous eruptions.

Its dose is from two or three grains, to six, eight, or ten: four grains generally operate briskly without vomiting, and eight or ten grains usually vomit briskly, and afterwards purge downwards.

It is at present much more esteemed by painters in water-colours, than by physicians.

GAME, *Ludus*, in general, signifies any diversion, or sport, that is performed with regularity, and restrained to certain rules. See the article *GAMING*.

GAMES, *Ludi*, in antiquity, were public diversions, exhibited on solemn occasions. Such, among the Greeks, were the Olympic, Pythian, Isthmian, Nemean, &c. games; and, among the Romans, the Apollinarian, Circensian, Capitoline, &c. games. See the articles *OLYMPIC*, *PYTHIAN*, &c.

GAMELIA, *γαμηλια*, in Grecian antiquity, a nuptial feast, or rather sacrifice, held in the ancient Greek families on the day before marriage; thus called, from a custom they had of shaving themselves on this occasion, and presenting their hair to

to some deity to whom they had particular obligations.

GAMELION, a poem or composition in verse on the subject of a marriage, commonly called *epithalamium*. See *EPITHALAMIUM*.

GAMING, the art or act of performing or practising any game, particularly a game of hazard, and this generally for stakes or a sum of money. See *Laws of CHANCE*.

GAMMUT, *GAM*, *GAMMA*, or *GAMMAUT*, in music, a scale whereon we learn to sound the musical notes, *ut, re, mi, fa, sol, la*, in their several orders and dispositions. See *NOTE* and *SCALE*.

The invention of this scale is owing to Guido Areteine; though it is so properly an invention as an improvement on the diagram, or scale of the Grecians. See the article *DIAGRAM*.

The gammut is also called the harmonical hand, by reason that Guido made first use of the figure of the hand to demonstrate the progression of his sounds.

Guido, finding the diagram of the ancients of too small an extent, added five more chords or notes to it; one below the *proslambanomenos* of the ancients, and four above the *hyperbolæon*. The first he called *hypoproslambanomenos*, and denoted it by the letter *G*, or the Greek *Γ*, *gamma*; which note being at the head of the scale, occasioned the whole scale to be called by the name of *gamm*, or *gammut*. This scale is divided into three series or columns, the first called *durum*, the second *natural*, and the third *molle*, &c.

GAMMUT, or *GAMM*, is also the first or gravest note in the modern scale of music, the reason of which is shewn under the preceding article.

GANDER, in ornithology, the male of the goose kind; one of which, it is said, will serve five geese. See *GOOSE*.

GANGLIO, or *GANGLION*, in surgery, a hard tubercle, generally moveable, in the external or internal part of the carpus, upon the tendons or ligaments in that part, usually without any pain to the patient. Though ganglions so nearly resemble an encysted tumour, that Celsus makes them one and the same; yet their differences may appear, if it were only from their different seats; ganglions being confined to the tendons and ligaments of the hands and feet, whereas encysted tumours are not restrained to any part of the body. See the article *ENCYSTED*.

With regard to the cause of ganglions, they seem generally to proceed from an inspissation of the viscid juices, which are let out, and lodged betwixt the fibres and membranes, when the tendons and ligaments of those parts have been injured by a fall, blow, strain, contusion, or the like, in which case they gradually increase more or less, as long as the fibres yield; the juices find vent so as to advance to the

the size of a filbert, walnut, or even a pigeon's egg: some are oblong, round, or oval, with an equal or uneven surface; some of them which are recent, may be easily dispersed; and others, which have been of long standing, hardly yield to any remedies but the knife.

The infiltrated matter of a recent ganglion may often be happily dispersed by barely rubbing the tumour well every morning with the salting saliva, and binding a plate of lead on it afterwards for several weeks successively. Many attribute a greater discutient virtue to the lead, when it has first had some mercury rubbed on it. Forestus, and others, advise the use of a plaster of ammoniac and mercury, and often to rub them with oil of soap. Others write, that a cure may be readily performed, if the patient lays his hand upon a table, and strikes on the tumour with his fist: but care should be taken not to injure the bones, tendons, or other parts of the hand, in striking the tumour; and the same care must be taken if there is a necessity of having recourse to caustics or incision, in order to remove them.

GANGRENE, a very great and dangerous degree of inflammation, wherein the parts affected begin to corrupt, and put on a state of putrefaction. A gangrene is distinguished from a sphacelus, inasmuch as this latter is not an incipient but an absolute and perfect corruption, or death of the parts, already made. See the article **SPHACELUS**.

A gangrene may be discovered generally from the following signs; namely, the inflammation, with its symptoms, which have all along been very violent, do generally undergo a sudden change, as if they were going off. The parts which were before swelled and tense, do now grow soft and flaccid, and upon pressing with the finger on the skin and fat, its impression remains behind, as in an oedema; at length the cuticula separates from the cutis, often rising up in blisters, like those on burns, filled with a reddish, yellowish, and black humour; and the sense of the limb is in some degree diminished. See the article **OEDEMA**.

A gangrene is for the generality never without danger, because it easily changes into a sphacelus, or intire mortification, which never admits of cure but by taking off the dead parts. But a gangrene which is slight, incipient, and not spread far, but only affects the skin and fat, is not very difficult to cure; especially when it happens in a young and stout patient, in a mild and temperate season, and does little or no injury to the muscles and nerves: but the larger, more violent, and confirmed is the gangrene, and the faster it spreads, the more difficult it is generally to effect a cure, especially in an old or weak patient; or in an ill habit of body, from a dropsy, phthisis, or scorbutus: the weather also being too hot, or very cold, or the parts affected being near the thorax, or abdomen, may

make the case more dangerous. Nor can this case be neglected without the utmost danger of life, or its suddenly turning into a sphacelus.

GANNET, in ornithology, a bird of the *Iarus* or gull-kind, frequent on the western coasts of England.

It is equal in size to the common duck. The upper part of the body is of a deep rusty ferrugineous colour, much like that of the common buzzard; and the breast and belly are also brown, but paler. It is an extremely singular species, its whole aspect, in some degree, approaching to that of some of the larger birds of prey.

GANTLET, or **GAUNTLET**, a large kind of glove, made of iron, and the fingers covered with small plates. It was formerly worn by cavaliers, when armed at all points.

GAOL, a prison, or place of legal confinement.

GAOL-DELIVERY, is where a commission or patent is granted by the king in the nature of a letter, to certain persons, who are thereby appointed his justices; or to two or three of them, authorizing them to deliver his gaol, at such a place, of the prisoners contained therein; and for that end it commands them to meet at such a place, at the time they themselves shall appoint, when the sheriff of the county is commanded to bring all the prisoners in the gaol before them, &c. 4 *Inst.* 168.

GARBLER of Spices, an ancient officer in the city of London, who is authorized to go into shops, ware houses, &c. there to view and search drugs, spices, &c. and see that they were garbled or cleaned from the dross and dust wherewith they are mixed.

GARDANT, or **GUARDANT**, in heraldry, denotes any beast full-faced, and looking right forward.

GARDEN, a plot of ground, cultivated and properly ornamented with a variety of plants, flowers, fruit, &c.

Gardens are usually distinguished into flower-garden, fruit-garden, and kitchen-garden; the first of which, being designed for pleasure and ornament, is to be placed in the most conspicuous part, that is, next to the back front of the house; and the two latter being designed for use, should be placed less in sight. But though the fruit and kitchen-gardens are here mentioned as two distinct gardens, yet they are now usually in one; and that with good reason, since they both require to be placed out of the view of the house. See **KITCHIN-GARDEN**.

In the choice of a place proper for a garden, the most essential points to be considered are the situation, the soil, the exposure, water, and prospect.

1. As to the situation, it ought to be such a one as is wholesome, and in a place neither too high nor too low; for if a garden be too high, it will be exposed to the winds, which are very prejudicial to trees;

trees; and if it be too low, the dampness, the vermin, and the venomous creatures that breed in ponds, and marshy places, add much to their insalubrity. The most happy situation is on the side of a hill, especially if the slope be easy, and in a manner imperceptible; if a good deal of level ground be near the house; and if it abounds with springs of water; for, being sheltered from the fury of the winds, and the violent heat of the sun, a temperate air will be there enjoyed; and the water that descends from the top of the hill, either from springs or rain, will not only supply fountains, canals, and cascades, for ornament, but when it has performed its office, will water the adjacent valleys, and, if it be not suffered to stagnate, will render them fertile and wholesome. Indeed if the declivity of the hill be too steep, and the water be too abundant, a garden on the side of it may frequently suffer, by having the trees torn up by torrents and floods; and by the tumbling down of the earth above, the walls may be demolished, and the walks spoiled. It cannot, however, be denied, that the situation on a plain, or flat, has several advantages which the higher situation has not: for floods and rain commit no damage; there is a continued prospect of champaigns, intersected by rivers, ponds, and brooks, meadows and hills, covered with woods or buildings; besides, the level surface is less tiresome to walk on, and less changeable, than that on the side of a hill, since terrace-walks and steps are not there necessary; but the greatest disadvantage of flat gardens, is the want of those extensive prospects which rising grounds afford.

2. A good earth, or soil, is next to be considered; for it is scarce possible make a fine garden in a bad soil; there are indeed ways to meliorate ground, but they are very expensive; and sometimes when the expence has been bestowed of laying good earth three feet deep over the whole surface, a whole garden has been ruined, when the roots of the trees have come to reach the natural bottom.

To judge of the quality of the soil, observe whether there be any heath, thistles, or such like weeds, growing spontaneously in it; for they are certain signs that the ground is poor. Or if there be large trees growing thereabouts, observe whether they grow crooked, ill-shaped, and grubby; and whether they are of a faded green, and full of moss, or infested with vermin; if this be the case, the place is to be rejected: but, on the contrary, if it be covered with good grass fit for pasture, you may then be encouraged to try the depth of the soil. To know this, dig holes in several places, six feet wide, and four feet deep; and if you find three feet of good earth, it will do very well; but less than two will not be sufficient. The quality of good ground is neither to be stony, nor too hard to work; neither too dry, too moist, nor too sandy and light;

nor too strong and clayey, which is the worst of all for gardens.

3. The next requisite is water, the want of which is one of the greatest inconveniences that can attend a garden, and will bring a certain mortality upon whatever is planted in it, especially in the greater droughts that often happen in a hot and dry situation in summer; besides its usefulness in fine gardens for making fountains, canals, cascades, which are the greatest ornaments of a garden.

4. The last thing to be considered is the prospect of a fine country; and though this is not so absolutely necessary as water, yet it is one of the most agreeable beauties of a fine garden: besides, if a garden be planted in a low place that has no kind of prospect, it will not only be disagreeable, but unwholesome.

In the laying out and planting of gardens, the beauties of nature should always be studied; for the nearer a garden approaches to nature, the longer it will please. The area of a handsome garden may take up thirty or forty acres, but not more; and the following rules should be observed in the disposition of it:—There ought always to be a descent at least three steps from the house to the garden; this will render the house more dry and wholesome, and the prospect on entering the garden more extensive. The first thing that should present itself to view, should be an open lawn of grass, which ought to be considerably broader than the front of the building; and if the depth be one-half more than the width, it will have a better effect: if on the sides of the lawn there are trees planted irregularly, by way of open groves the regularity of the lawn will be broken, and the whole rendered more like nature. For the convenience of walking in damp weather, this lawn should be surrounded with a gravel walk, on the outside of which should be borders, three or four feet wide, for flowers: and from the back of these, the prospect will be agreeably terminated by a slope of ever-green shrubs, which, however, should never be suffered to exclude agreeable prospects, or the view of handsome buildings. These walks may lead through the different plantations, gently winding about in an easy natural manner, which will be more agreeable than either those long straight walks, too frequently seen in gardens, or those serpentine windings, that are twisted about into so many short turns, as to render it difficult to walk in them: and as no garden can be pleasing where there is a want of shade or shelter, these walks should lead as soon as possible into plantations, where persons may walk in private, and be sheltered from the wind. Where the borders of the gardens are fenced with walls or pales, they should be concealed with plantations of flowering shrubs intermixed with laurels and other ever-greens, which will have a good effect, and at the same time conceal the fences, which are disagreeable, when left naked and exposed to the sight.

Groves

Groves are the most agreeable parts of a garden, so that there cannot be too many of them; only that they must not be too near the house, nor be suffered to block up agreeable prospects. To accompany parterres, groves opened in compartments, quincunxes, and arbour-work with fountains, &c. are very agreeable. Some groves of ever-greens should be planted in proper places, and some squares of trees of this kind may also be planted among the other wood. See QUINCUNX, &c.

Narrow rivulets, if they have a constant stream, and are judiciously led about a garden, have a better effect than many of the large stagnating ponds or canals so frequently made in large gardens. When wildernesses are intended, they should not be cut into stars and other ridiculous figures, nor formed into mazes or labyrinths, which in a great design appear trifling. Buildings, statues, and vases, appear very beautiful; but they should never be placed too near each other: magnificent fountains are also very ornamental; but they ought never to be introduced, except there be water to keep them constantly running. The same may also be observed of cascades and other falls of water. See the articles CASCADE, FOUNTAIN, &c.

In short, the several parts of a garden should be diversified; but in places where the eye takes in the whole at once, the two sides should be always the same. In the business of designs, the aim should be directed at what is natural, great, and noble. The general disposition of a garden, and of its parts, ought to be accommodated to the different situations of the ground, to humour its inequalities, to proportion the number and sorts of trees and shrubs to each part, and to shut out from the view of the garden no objects that may become ornamental. And before a garden is planned out, it ought ever to be considered, what it will be when the trees have had twenty years growth. *Miller's Gard. Dict.*

GARDENING, a branch of agriculture, containing the cultivation of gardens.

The art of gardening teaches how to lay out properly the different parts of a garden so as to make it not only the most useful, but also the most convenient and ornamental according to its situation; it likewise shews how to prepare and adapt the various kinds of soil for sowing and planting the different kinds of seeds, trees, &c. as also their proper seasons of sowing and managing when growing up, according to their several natures; with the divers methods of increasing and propagating plants, whether by cuttings, layers, grafting, inoculation, &c.

As to the several parts and operations of gardening, see them described under their respective articles, as SOWING, PLANTING, TRANSPLANTING, GRAFTING, INOCULATION, PRUNING, NURSERY, HOT-BED, GREEN-HOUSE, WALK, TERRACE, ALLEY, AVENUE, ARBOUR, GROVE, ESPALIERS, STANDARDS, &c.

GARCINIA, in botany, a tree which rises with an upright stem to about twenty feet high; the branches are placed opposite, in pairs, standing oblique to each other; the leaves are spear-shaped and entire, of a bright green on their upper side, and olive-coloured underneath, and about seven or eight inches long. The flower is roseaceous, consisting of four roundish patent petals of a dark red colour, with sixteen erect stamina. The fruit is a large unilocular coriaceous berry, containing eight hairy and fleshy seeds, which are convex on one side, angular on the other, and surrounded with a soft juicy pulp of a delicious flavour, partaking of the strawberry and grape, which makes it one of the richest fruits in the world. This tree is a native of the inland parts of Mexico and the Molucca islands, and is sometimes called mangostan.

GARGARISM, in medicine, is sometimes taken, in a large sense, for every collution of the mouth; but, strictly speaking, it signifies a liquid medicine, appropriated to affections of the mouth, gum, fauces, larynx, and sometimes of the head, received into the mouth, and there used by way of collution, without deglutition.

GARIDELLA, in botany, a genus of decandrious plants; it hath no flower petals, but, in their stead, are placed five long equal and bilabiated nectaria. The fruit consists of three oblong compressed acuminate capsules, formed of two valves inclosing several small seeds.

GARLAND, among sailors, a sort of net used by the different messes of a ship of war to hang their provisions in, in the apartment where they eat and sleep.

GARLIC, *Allium*, in botany, a plant with a bulbous root, consisting of several membranes, and is of a whitish colour with a purplish cast; the leaves are oblong, and not fistulous as those of the onion, but in their general characters they agree, and are therefore classed by Linnaeus together. See ONION.

Garlic is easily propagated, by planting their cloves or small bulbs in the spring, in beds about four or five inches asunder; in the middle of June the leaves should be tied in knots to prevent their running to seed, and then the bulb will be greatly enlarged: towards the end of July the leaves will begin to wither, and then the root should be taken out of the ground, and hung up in a dry room.

Garlic is proper to warm and stimulate the solids, and to dissolve the gross clammy fluids, whence it is good in cold constitutions and in moist asthma, as well as all defluxions of the breast; it is likewise very diuretic, as appears by its smell in the urine, and upon that account is serviceable in dropsies, for it will sometimes cure it without any other medicine; but it should be avoided in all inflammatory dispositions and hot diseases.

GARNET, among sailors, a sort of tackle or

complication of pulleys, fixed to the main-slay of a merchant-ship to hoist the cargo in and out at the time of lading and delivering her.

Also a rope fixed to the lower corners or clues of the main-sail and fore-sail to draw them up to the yard occasionally, and hence called clue-garnet. See the article CLUE-GARNET.

GARNET, *Granatus*, in natural history, a very beautiful gem, of a red colour, with an admixture of bluish.

When pure and free from blemishes, it is little inferior, in appearance, to the oriental ruby, tho' only of a middle degree of hardness between the sapphire and common crystal. It is found of various sizes, from that of a pin's head to an inch in diameter.

Among our lapidaries and jewellers, genuine garnets are known by different names, according to their different degrees of colour. 1. The garnet, simply so called, is the finest and most valuable kind, being of a very deep blood-red, with a faint admixture of blue. 2. The rock-ruby, a name very improperly given to the garnet, when it is of a very strong but not deep red, and has a fairer cast of the blue; this is a very beautiful gem. 3. The forane or ferain garnet, that of a yet brighter red, approaching to the colour of native cinnabar, with a faint blue tinge. 4. The almandine, a garnet only a little paler than that called the rock-ruby.

Garnets are very properly distinguished into the oriental and occidental kinds, as being found in Europe as well as the East-Indies. The oriental ones are principally brought from Calicut, Cananor, and Cambay; and the European ones are common in Italy, Hungary, and Bohemia.

Some authors have supposed the deeper-coloured garnet to be the same with the carbuncle of the ancients, from which it really differs; since, on receiving the sun's beams, it never gives so true a fire-colour as the carbuncle. See CARBUNCLE.

GARRISON, in the art of war, a body of forces, disposed in a fortress, to defend it against the enemy, or to keep the inhabitants in subjection; or even to be subsisted during the winter season; hence, garrison and winter-quarters are sometimes used indifferently for the same thing; and sometimes they denote different things. In the latter case, a garrison is a place wherein forces are maintained to secure it; and where they keep regular guard, as a frontier town, a citadel, castle, tower, &c. The garrison should always be stronger than the townsmen.

Winter-quarters signify a place where a number of forces are laid up in the winter season, without keeping the regular guard. See WINTER-QUARTERS.

GARRISON-TOWN, a strong place in which troops are quartered, and do duty, for the security

thereof, keeping strong guards at each port, and a main guard in the market-place.

Order of the GARTER, a military order of knighthood, the most noble and ancient of any lay-order in the world, instituted by king Edward III. This order consists of twenty-six knights companions, generally princes and peers, whereof the king of England is sovereign or chief. They are a college or corporation, having a great and little seal.

Their officers are a prelate, chancellor, register, king at arms, and usher of the black rod. They have also a dean with twelve canons, and petty canons, vergers, and twenty-six pensioners or poor knights. The prelate is the head. This office is vested in the bishop of Winchester, and has ever been so. Next to the prelate is the chancellor, which office is vested in the bishop of Salisbury, who keeps the seals, &c. The next is the register, who by his oath is to enter upon the registry the scrutinies, elections, penalties, and all other acts of the order, with all fidelity. The fourth officer is garter, and king at arms, being two distinct offices united in one person. Garter carries the rod and scepter at the feast of St. George, the protector of this order, when the sovereign is present. He notifies the elections of new knights, attends the solemnity of their installations, carries the garter to the foreign princes, &c. He is the principal officer within the college of arms, and chief of the heralds. See KING at Arms.

All these officers, except the prelate, have fees and pensions. The college of the order is seated in the castle of Windsor, with the chapel of St. George, and the chapter-house, erected by the founder for that purpose. The habit and ensign of the order are a garter, mantle, cap, george, and collar. The four first were assigned the knights companions by the founder; and the george and collar by Henry VIII. The garter challenges pre-eminence over all the other parts of the dress, by reason that from it the noble order is denominated; that it is the first part of the habit presented to foreign princes, and absent knights, who, and all other knights elect, are therewith first adorned; and it is of so great honour and grandeur, that by the bare investiture with this noble ensign, the knights are esteemed companions of the greatest military order in the world. It is worn on the left leg between the knee and calf, and is enamelled with this motto, *HONI SOIT QUI MAL Y PENSE*; i. e. "Shame to him that thinks evil hereof." The meaning of which is, that king Edward having laid claim to the kingdom of France, retorted shame and defiance upon him that should dare to think amiss of the just enterprise he had undertaken, for recovering his lawful right to that crown; and that the bravery of those knights whom he had elected into this order,

was such as would enable him to maintain the quarrel against those that thought ill of it.

The mantle is the chief of those vestments made use of upon all solemn occasions. The colour of the mantle is by the statutes appointed to be blue. The length of the train of the mantle only distinguishes the sovereign from the knights companions. To the collar of the mantle is fixed a pair of long strings, anciently wove with blue silk only, but now twisted round, and made of Venice gold and silk, of the colour of the robe, with knobs, or buttons, and tassels at the end. The left shoulder of the mantle has from the institution been adorned with a large garter, with the device *HONI SOIT*, &c. Within this is the cross of the order, which was ordained to be worn at all times by king Charles I. At length the star was introduced, being a sort of cross, irradiated with beams of silver.

The collar is appointed to be composed of pieces gold in fashion of garters, the ground enamelled blue, and the motto gold. See *COLLAR*.

The manner of electing a knight companion into this most noble order, and the ceremonies of investiture, are as follow :

When the sovereign designs to elect a companion of the garter, the chancellor belonging to this order draws up the letters, which passing both under the sovereign's sign manual and signet of the order, are sent to the person by garter principal king at arms, and are in this manner, or to the same effect :— " We, with the companions of our most noble order of the garter, assembled in chapter, holden this present day at our castle at Windsor, considering the virtuous fidelity you have shewn, and the honourable exploits you have done in our service, by vindicating and maintaining our right, &c. have elected and chosen you one of the companions of our order. Therefore, we require you to make your speedy repair unto us, to receive the ensigns thereof, and be ready for your installation upon the — day of this present month, &c."

The garter, which is of blue velvet bordered with fine gold wire, having commonly the letters of the motto of the same, is, at the time of election, buckled upon the left leg, by two of the senior companions, who receive it from the sovereign, to whom it was presented upon a velvet cushion by garter king at arms, with the usual reverence, whilst the chancellor reads the following admonition, enjoined by the statutes :— " To the honour of God omnipotent, and in memorial of the blessed martyr St. George, tye about thy leg, for thy renown, this noble garter; wear it as the symbol of the most illustrious order, never to be forgotten, or laid aside; that thereby thou mayest be admonished to be courageous, and having undertaken a just war in which thou shalt be engaged, thou mayest stand firm, valiantly fight, and successively conquer."

The princely garter being thus buckled on, and

the words of its signification pronounced, the knight elect is brought before the sovereign, who puts about his neck, kneeling, a sky-coloured ribbon, whereunto is appendant, wrought in gold within the garter, the image of St. George on horseback, with his sword drawn, encountering with the dragon. In the mean time the chancellor reads the following admonition :— " Wear this ribbon about thy neck, adorned with the image of the blessed martyr and soldier of Christ, St. George, by whose imitation provoked, thou mayest so overpass both prosperous and adverse adventures, that having stoutly vanquished thy enemies, both of body and soul, thou mayest not only receive the praise of this transient combat, but be crowned with the palm of eternal victory."

Then the knight elected kisses the sovereign's hand, thanks his majesty for the great honour done him, rises up, and salutes all the companions severally, who return their congratulations.

Since the institution of this order, there have been eight emperors, and twenty-eight kings, besides numerous sovereign princes, enrolled as companions thereof. Its origin is somewhat differently related : the common account is, that it was erected in honour of a garter of the countess of Salisbury, which she dropped dancing with king Edward, and which that prince picked up; but our best antiquarians think it was instituted on account of the victory over the French at Cressly, where the king ordered his garter to be displayed as a signal of the battle.

GAS, among chemists, a term made use of by Helmont, to signify, in general, spirit incapable of coagulation, such as proceeds from fermented wine.

GASKET, among sailors, a sort of platted cord fastened to the sail-yards of a ship, to furl or tie up the sail to the yard : it is used by wrapping it round the yard and sail, the latter of which is rolled up close to the former for that purpose.

GASTRO-EPIPLOIC VEIN, a vein that opens into the vena portæ. See *VEIN*.

GASTRIC, in general, something belonging to the stomach. See *STOMACH*.

GASTRIC JUICE, *gastricus succus*, among physicians, a thin, pellucid, spumous, and saltish liquor, which continually distils from the glands of the stomach for the dilution of the food. See the article *FOOD*.

GASTRIC VESSELS, in anatomy, the arteries and veins of the stomach. See the articles *ARTERY* and *VEIN*.

GASTROCNEMIUS, in anatomy, the name of two thick, pretty broad, and oblong muscles, which form a great part of what is called the calf of the leg. They are situated laterally with respect to each other under the poples.

GASTROCNEMIUS is also the name of one of the extensor-muscles of the foot.

GASTRORAPHY, *γαστρογραφία*, in surgery, the operation of fowling up wounds of the abdomen.

GASTROTOMY, *γαστροτομία*, in surgery, the cutting open the abdomen and uterus, as in the the Cæsarian section. See the article **CÆSARIAN**.

GATE, in architecture, a large door, leading, or giving entrance into a city, town, castle, palace, or other considerable building; or a place giving passage to persons, horses, coaches, or waggons, &c. As to their proportion, the principal gates for entrance, through which coaches and waggons are to pass, ought never to be less than seven feet in breadth, nor more than twelve, which last dimension is fit only for large buildings. The height of the gate is to be $1\frac{1}{2}$ of the breadth, and somewhat more; but as for common gates in inns, under which waggons go loaded with hay, straw, &c. the height of them may be twice their breadth.

Paired GATES, such as are set up in fences for shutting up the passages into fields, and other inclosures.

These are of two sorts, either of sawed or cleft timber.

GATE, in the manege, the going or pace of a horse.

GAVELET, in law, an ancient and special cessavit used in Kent, where the custom of gavelkind continues, by which the tenant, if he withdraws his rent and services due to the lord, forfeits his lands and tenements.

GAVELET, in London, is a writ used in the hustings, given to lords of rents in the city of London.

GAVELKIND, a tenure or custom belonging to lands in the county of Kent, by which the lands of the father are, at his death, equally divided among all his sons; or the land of a deceased brother, in case he leaves no issue, among all his brethren. This is by some called ancient socage-tenure; the custom came from our Saxon ancestors, among whom the inheritance of lands did not descend to the eldest, but to all the sons alike; and the reason why it was retained in Kent is, because the Kentish men were not conquered by the Normans in the time of William I.

The particular customs attending this tenure are, that the heir at the age of fifteen, may give or sell his lands in gavelkind; and though the father is attainted of treason and felony, and suffers death, the son shall inherit. A wife shall be endowed of a moiety of the gavelkind-lands, of which her husband died seized, during her widowhood. Likewise a husband may be tenant by curtesy of half his wife's lands, without having any issue by her; but if he marries again, not having issue, he forfeits his tenancy.

GAVELMAN, a tenant liable to pay tribute.

GAVELMED, the duty of mowing grafs, required by the lord of his customary tenants.

GAUGE, or **GAGE**. See **GAGE**, or **GAGE**.
GAUGE-LINE, on the gauging-rod. See the article **GAUGING**.

GAUGE-POINT, of a solid measure, the diameter of a circle, whose area is equal to the solid content of the same measure. Thus, the solidity of a wine gallon being 231 cubic inches, if you conceive a circle to contain so many inches, the diameter of it will be 17.15; and that will be the gauge-point of wine-measure. And an ale-gallon, containing 282 cubic inches, by the same rule, the gauge-point for ale-measure will be found to be 19.15. After the same manner, may the gauge-point of any foreign measure be obtained; and from hence may be drawn this consequence, that when the diameter of a cylinder, in inches, is equal to the gauge-point of any measure, given likewise in inches, every inch in length thereof will contain an integer of the same measure, e. g. in a cylinder whose diameter is 17.15 inches, every inch in height contains one entire gallon in wine-measure; and in another, whose diameter is 18.95 inches, every inch in length contains one ale-gallon.

GAUGER, a king's officer who is appointed to examine all tuns, pipes, hogheads, and barrels of wine, beer, ale, oil, honey, &c. and give them a mark of allowance, before they are sold in any place within the extent of his office.

GAUGING, the art of measuring the contents of all kinds of vessels, thereby to determine the quantity of liquids, &c. they contain.

Gauging is a branch of stereometry. The principal vessels that come under its operation are pipes, barrels, rundlets, and other casks; also coolers, fats, backs, stills, &c.

The solid content of cubical, parallelopipedal, and prismatic vessels is found in cubic inches, &c. by multiplying the area of the base by the perpendicular altitude. And the area of cylindrical vessels is found by multiplying the area of the circular base by the perpendicular altitude.

Before the content of a cask can be known, its form or shape must be considered; for though the diameters and length of one cask may be equal to those of another, yet one of them may contain several gallons more than the other; and therefore the content of all casks cannot be found by the same rule. Most writers, therefore, in treating of this subject, have taken it for granted, that every common cask is in one of the following solids, viz.

1. The middle frustum of a spheroid.
2. The middle frustum of a parabolical spindle.
3. The middle frustum of two parabolical conoids abutting upon one common base.
4. The middle frustum of two cones abutting upon one common base.

Accordingly, they have laid down rules for finding the contents of these solids, and by those rules they suppose the content of any cask may be found.

See

See the method of finding the area of these figures under their proper articles.

From what has been said, it follows, that if we are not exact in assigning the cask its true form, it is impossible we should ever be exact in ascertaining its contents. Now, it is evident to those conversant in these affairs, that there never was any cask in the shape of any one of those solids whose names they bear, unless it can be supposed that it was affected by chance, the cooper never intending them for such: and though it should be admitted that a cask may approach nearly to the form of such a solid, yet what officer had any rule to direct in ascertaining its true form, or to which of the varieties it belonged? Whence it follows, that the best method of gauging all kinds of casks is to reduce them to cylinders; that is, to find a mean diameter between the head and the bung, whence its content will always be found exceedingly near the truth. The method is this:

To the square of the bung diameter, add the square of the head, and four times the square of the mean diameter; multiply this sum by the length of the cask, and divide by 2154.3 for ale, and by 1764.71 for wine, which will give the content respectively.

GAUGING-Rule is an instrument commonly made of box, and sometimes ivory, exactly a foot long, one inch and two-tenths broad, and $\frac{3}{4}$ of an inch thick; it consists of four parts, viz. a rule and three small scales or sliding-piece fitted nicely with grooves to slide in it.

Four-foot GAUGING-Rod, a rod usually made of box-wood, and consists of four rules, each a foot long, and about half an inch square, joined together by three brass joints, by which means the rod is rendered four feet long, when the four rules are quite opened, and but one foot in length when they are folded together.

On the first face of this rod is placed a line of inches (and sometimes with it a line of ale areas) decimally divided, whose use is to take dimensions necessary for gauging vessels either for ale, wine, malt, &c.

Two diagonal lines are placed near the line of inches, one for ale, the other for wine.

The diagonal line of a cask is found by putting the rod in at the bung to the intersection of the head of the vessel, with the staves opposite to the bung-hole.

By the bung, head, and length of a cask, we can find its diagonal line; whence, by having the contents of two similar casks, and the diagonal of one of them given, we can find the diagonal line of the other; for as the content of any cask, in ale or wine gallons, is to the cube of its diagonal, so is the content of any other cask (similar to the former) to the cube of its diagonal, whose cube-root is the diagonal required.

Lines adapted to the London casks are placed on the other faces of this four-foot gauging-rod, viz. 1. a line for a butt standing; 2. for a butt lying, each of which contains 108 gallons, beer-measure; 3. a line for a hoghead, containing 54 gallons; 4. a line for the barrel of 36 gallons; 5. a line for a kilderkin of 18 gallons; 6. a line for a firkin of nine gallons. Then, to gauge any of these casks, there is no more to do than to put in your rod perpendicular at the bung, &c. and if the cask is not full it gives you the quantity of liquor in the cask.

For the same purpose there are also lines put on four-foot gauging-rods for wine-measure; as 1. a tun of 252 gallons; 2. a butt of 126 gallons; 3. a puncheon of 84 gallons; 4. a hoghead of 63 gallons; 5. a tierce of 42 gallons; 6. a barrel of $31\frac{1}{2}$ gallons; 7. a rundlet of 18 gallons; and, lastly, an anchor of 10 gallons; by these lines all brandies and oils are gauged.

These lines for London casks are made by setting the vessel level, and pouring in one gallon of water, and then put the rod downright into the bung-hole (if it is a lying cask) or at the head (if a standing cask) and where the surface of the water cuts the rods, make the division for one gallon; then pour in another gallon, and where the surface of the water cuts the rod, make divisions for two gallons; proceed thus by pouring in one gallon successively after another, and make divisions at every place on the face of the rod, to which the water rises, till the cask be full, and then you have the scale for that cask properly divided. Proceed in the same manner for every one of the London casks above-mentioned, and all the lines will be finished when figured.

Note, The divisions for quarts, marked by dots on the rod, are made by pouring in a quart of water successively, and that you may not be at a loss to know what cask is in hand, the rod will shew you; for by measuring the depth of the bung, &c. if it cut 36, it is a barrel; if 18, it is a kilderkin, &c. and by the line for that cask you must take its ullage; that is, the quantity of liquor either drawn out, or remaining in the cask. For the uses of the line of number, &c. see GUNTER'S Line.

GAULTHERIA, in botany, a genus of plants, whose flower cup is a double persistent perianthium, the corolla is monopetalous and ovated. The fruit is a roundish pentagonal depressed capsule, with five cells and five valves, containing a number of subovate angular oleous seeds.

GAUNTLET, or **GANTLET**. See the article GANTLET.

GAVOTTA, or **GAVOTTE**, is a kind of dance, the air of which has two brisk and lively strains in common time, each of which strains are played twice over; the first has usually four or eight bars, and the second contains eight, twelve, or more.

Tempi di GAVOTTA is when only the time or 3 X move-

G E L

movement of a gavotte is imitated, without any regard to the measure, or number of bars or strains.

GAURA, in botany, a genus of plants, whose flower hath four oblong petals, with eight filiform stamina. The fruit is an ovate tetragonal capsule, compressed at the angles, and contains a solitary oblong angulated seed.

GAURS, in matters of religion, an ancient sect of the magicians in Persia. They have a suburb at Ispahan, which is called Gaurabad, or the town of the Gaurs, where they are employed only in the meanest and vilest drudgery: but they chiefly abound in Kerman, the barrenest province in all Persia, where the Mahometans suffer them to live with some freedom, and in the full exercise of their religion. Some years ago many of them fled into India, where their posterity remain to this day.

They are a poor harmless sort of people, zealous in their superstition, rigorous in their morals, and exact in their dealings: they profess the worship of one God alone, the belief of a resurrection, and a future judgment, and utterly detest all idolatry; though the Mahometans believe them to be the most guilty of it. It is true; they perform their worship before fire, for which they have an extraordinary veneration, as believing it to be the most perfect emblem of the deity. They have the same veneration for Zoroaster that the Jews have for Moses, esteeming him a prophet sent from God.

GAWSE, or **GAWZE**, in commerce, a very slight, thin, open kind of stuff, made of silk, and sometimes of thread; there are also figured gawzes, and some with gold or silver flowers on a silk ground.

GAZONS, in fortification, pieces of fresh earth, covered with grass, and cut in form of a wedge, about a foot long and half a foot thick, to line the outfiles of works made of earth, as ramparts, parapets, &c. The first bed of gazons is fixed with pegs of wood; the second bed should be so laid as to bind the former, by being placed over its joins; and so continued till the works are finished. Betwixt these beds it is usual to sow all sorts of binding herbs, in order to strengthen the rampart.

GEERS, in country affairs, the trappings and other harness belonging to draught-horses or oxen.

GEESE, in ornithology. See **GOOSE**.

GEHENNA, a term mentioned in several parts of scripture, which our English translators have rendered hell. See **HELL**.

GELATINOUS, in pharmacy and medicine, any thing approaching to the glutinous consistence of a gelatina, or jelly.

GELD, in our old customs, a Saxon word signifying money, or tribute: also a compensation for some crime committed. See the article **GILD**.

GELDER-ROSE, in botany. See **VIBURNUM**.

G E L

GELDING, the operation of castrating any animal, particularly horses.

The operation consists in cutting out the testicles: in performing which, three things are to be observed: first, regard is to be had to their age; next, to the season of the year; and, lastly, to the state of the moon. For the first, if the operation is to be performed on a colt, he may be gelded at nine or at fifteen days old, if the testicles be come down, in regard the sooner he is gelt the better it will be for his growth, shape, and courage; though a horse may be gelt at any age, if proper care be taken in the cure. As for the second, the best time is about April or May, or else about the latter end of September. And for the third, the wane of the moon is the fittest time for performing the operation.

The manner of gelding is as follows: the beast being cast down on some soft place, the operator takes the stones between his foremost and his great finger, and slitting the cod, presses the stones forth: then taking a pair of nippers, made very smooth, either of steel, box, or brasil-wood, he claps the strings of the stones between them, very near to where the stones are set on, and presses them so hard, that there may be no flux of the blood; then, with a thin, drawing cauterizing iron, made red-hot, sears away the stone.

This done, he takes a hard plaster made of rosin, wax, and washed turpentine, well dissolved together, and melts it on the head of the strings: that being done, he sears them, and melts more of the salve, till such time as he has laid a good thickness of it upon the strings.

This being done to one stone, the nippers are loosened, and the like is done to the other; and the two slips of the cod are then filled with white salt, and the outside of the cod is anointed with hogsgrease; and thus they let him rise, and keep him in a warm stable, without tying him up.

If he swells much in his cods or sheath, they chase him up and down; and make him trot an hour in a day, and he soon recovers.

The manner of gelding a hog is as follows: the operator, after having made two cross slips, or incisions, on the middle of the stones, presses them out, and anoints the fore with tar. But another more general method, yet somewhat more dangerous, if not well done, is first to cut the stone on the top, and after having drawn that one forth, the operator puts in his fingers at the same slip, and, with a lancet, cuts the skin between the two stones, and by that slit presses out the other stone. Then having cleansed out the blood, he anoints the part with fresh grease: and thus there is but one incision made in the cod. Boar pigs ought to be gelt about six months old; yet they are commonly gelded about three weeks or a month old.

GELDING of a Lamb may be performed from the age

age of three days to three weeks or more, in the following manner: one is to hold the lamb between his legs, or in his lap, and turn him on his back, holding his fore-feet upright together (but if any black spots are seen in his flank, he must not be cut at all); then the cutter holding the tip of the cod in his left hand, cuts the lap of it an inch quite away; which done, he, with the foremoft fingers and thumbs of both hands, should softly slip down the cod over the stones, to the belly, and with his teeth, holding the left stone in his mouth, he draws it softly out the length of the string; after which he is to draw out the other stone in the same manner; then he spits in the cod, and anoints the lamb's flanks with fresh greafe, and so lets him go, and keeps stirring him up and down for two or three hours.

GEM, Gemma, in natural history, a common name for all precious stones, of which there are two classes, the pellucid and semipellucid.

The bodies composing the class of pellucid gems are bright, elegant, and beautiful fossils, naturally and essentially compound, ever found in small detached masses, extremely hard, pellucid, and of great lustre; composed of a very firm and pure matter, without any admixture of earthy substance, giving fire with steel, not fermenting with acid menstruums, and very difficultly calcinable in the fire.

The bodies composing the class of semipellucid gems, are stones naturally and essentially compound, not inflammable no soluble in water, found in detached masses, and composed of crystalline matter debased by earth: however, they are but slightly debased, and are of great beauty and brightness, of a moderate degree of transparency, and are usually found in small masses.

Many authors, not only among the ancients but the moderns, are full of the virtues and medicinal properties of precious stones, but their reputation, in this respect, is now greatly fallen.

Imitation or counterfeiting of GEMS in Glass. The art of imitating gems in glass, is too considerable to be passed without notice; some of the leading compositions therein we shall briefly mention, upon the authority of Neri. See **GLASS**.

These gems are made of pastes, and are no way inferior to the native stones, when carefully made and well polished, in brightness or transparency, but want their hardness. See the article **PASTE**.

The general rules to be observed in making the pastes are these. 1. That all the vessels in which they are made be firmly luted, and the lute left to dry before they are put into the fire. 2. That such vessels be chosen for the work as will bear the fire well. 3. That the powders be prepared on a porphyry stone, not in a metal mortar, which would communicate a tinge to them. 4. That the just

proportion in the quantity of the several ingredients be nicely observed. 5. That the materials be all well mixed, and if not sufficiently baked the first time, to be committed to the fire again, without breaking the pot: for if this be not observed, they will be full of blisters and air-bladders. 6. That a small vacuity be always left at the top of the pot, to give room to the swelling of the ingredients.

To make paste of extreme hardness, and capable of all the colours of the gems, with great lustre and beauty.—Take of prepared crystal, ten pounds; salt of pulverine, six pounds; sulphur of lead, two pounds; mix all these well together into a fine powder; make the whole, with common water, into a hard paste; and make this paste into small cakes of about three ounces weight each, with a hole made in their middle; dry them in the sun, and afterwards calcine them in the straightest part of a potter's furnace. After this, powder them, and levigate them to a perfect fineness on a porphyry-stone, and set this powder in pots in a glass furnace to purify for three days: then cast the whole into water, and afterwards return it into the furnace, where let it stand fifteen days, in which time all foulness and blisters will disappear, and the paste will greatly resemble the natural jewels. To give this the colour of the emerald, add to it brass thrice calcined; for a sea-green, brass simply calcined to a redness; for a sapphire, add zaffer, with manganese; and for a topaz, manganese and tartar. All the gems are thus imitated in this by the same way of working as the making of coloured glasses; and this is so hard, that they very much approach the natural gems.

The colour of all the counterfeit gems, made of the several pastes, may be made deeper or lighter, according to the work for which the stones are designed; and it is a necessary general rule, that small stones for rings, &c. require a deeper colour, and large ones, a paler: besides the colours made from manganese, verdigrease, and zaffer, which are the ingredients commonly used, there are other very fine ones which care and skill may prepare. Very fine red may be made from gold, and one not much inferior to that from iron; a very fine green from brass or copper; a sky-colour from silver; and a much finer one, from the granates of Bohemia.

GEMARA, in Jewish antiquity, a collection of decisions and determinations on the law, wrote after the Mishna was completed.

It was called gemara, or perfection, because it was considered as so perfect an explication of the law, that after it no farther additions could be made, or any thing more desired. It was otherwise called the Talmud. See **TALMUD**.

GEMELLUS, in anatomy, the name of two muscles, both of which are small, flat, and narrow, and situated almost transversely one above the other,

G E M

between the tuberosity of the ischium and the great trochanter, immediately below the pyriformis, and parted by the tendon of the obturator internus.

The superior and smallest gemellus is fixed to the lower part of the spine of the ischium, to the superior part of the small ischiatic notch, and is continued under the acetabulum, where it is bent downwards. The inferior and largest gemellus is fixed to the superior and back part of the tuberosity of the ischium, and bending upwards towards the other line, together with it forms a sort of irregular semicircle.

GEMINATED COLUMN. See the article COLUMN.

GEMINI, or the Twins, in astronomy, is the third in order, of the twelve zodiacal constellations; it is represented by two beautiful children embracing and looking each other affectionately in the face. (See Plate LVII.) The poets say they represent Castor and Pollux, sons of Jupiter and Leda, and brothers to Hellen, who, as Otway says,

— Was the cause of a long ten year's war,
And laid, at last, old Troy in ashes.

It consists of 85 stars, as in the following catalogue, being all that have ever been observed at the Royal Observatory : they are reduced to the beginning of the year 1770.

GEMMA, *Gem*, in natural history. See the article **GEM**.

Sal **GEMMÆ** is the purest and finest fossil salt, and an extremely fine and beautiful fossil. It is considerably hard and firm, and at least as pellucid as rock-crystal; but is frequently coloured throughout with a milky-white, which takes off greatly from its lustre; and as crystal is liable to be tinged with red, green, and yellow, so as to resemble rubies, sapphires, emeralds, and topazes, so this salt is sometimes tinged with these several colours; but rarely preserves the transparency of crystal under the same circumstances. See the article **SALT**.

GENDARMES, or **GENS D'ARMES**, in the French armies, a denomination given to a select body of horse, on account of their succeeding the ancient gendarmes, who were thus called from their being completely clothed in armour.

The king's body guards, the light-horse of the royal house, and the musqueteers, are at present reputed to belong to the gendarmerie.

The grand gendarmes are a troop composed of about two hundred and fifty gentlemen, who guard the king's person. The king himself is their captain, and one of the prime peers their captain-lieutenant, who has under him two lieutenants, three ensigns, three guidons, and other officers. There are besides these, gendarmes of the queen, the dauphin, &c.

GENDER, *Genus*, among grammarians, a division of nouns, or names, to distinguish the two sexes. See **NOUN** and **SEX**.

This was the original intension of gender; but, afterwards, other words, which had no proper relation either to the one sex or the other, had genders assigned them, rather out of caprice than reason; which is at length established by custom. Hence genders vary according to the languages, or even according to the words introduced from one language into another. Thus, *arbor*, in Latin, is feminine; but *arbre*, in French, is masculine: and *dens*, in Latin, is masculine; but *dent*, in French, is feminine. Nay, a gender has sometimes changed in the same language, according to time and occasion. Thus, *alvus*, according to Priscian, was an-

ciently masculine, but afterwards became feminine; and *navire* was anciently feminine in French, but is now masculine. In English we have no genders; indeed we express the difference of sex by different words; as *boar*, *sow*; *boy*, *girl*, &c. We have also twenty-four feminines distinguished from the males by varying the termination of the female into *ess*; as *actor*, *actress*; *prince*, *princess*; *heir*, *heir-ess*, &c. and we have a few words in which the feminine is distinguished from the masculines by the termination *ix*, as *executor*, *executrix*; *administrator*, *administratrix*, &c. which is all our language knows of any thing like genders.

The eastern languages, as well as the vulgar languages of the west, have only two genders, the masculine and the feminine. The Greek and Latin have besides, the neuter, common, and doubtful genders. This last indeed is not common, for it properly belongs only to the names of some animals, which are promiscuously joined both to masculine and feminine adjectives, to express their male or female, as *bos*, *canis*, *fus*, &c. They have also the epicene gender, which is not a different one, but serves promiscuously for either; including both the kinds under one single gender and termination: thus *vulpes*, a fox, though it signifies either the male or female, is really of the feminine gender, in Latin. And *custodias*, watchmen or centinels, are really feminine, though they signify men. This is common to all languages that have them. The Latin and Greek, in the neuter gender, do not regard them, having no relation to the male or female sex, but what fancy gives them, and the termination of certain words.

The Oriental languages frequently neglect the use of genders; and the Persian language has none at all, which is no disadvantage: the distinction of genders being entirely useless.

GENEALOGY, *γενεαλογία*, an enumeration of a series of ancestors; or a summary account of the relations and alliances of a person or family, both in the direct and collateral line.

GENERAL TERMS, among logicians, those which are made the signs of general ideas.

All things that exist, Mr. Locke observes, being particulars, it might be expected that words should be too in their signification: but we find it quite contrary; for most of the words that make all languages are general terms. This is the effect of reason and necessity. For,

First, it is impossible that every particular thing should have a distinct name, because it is impossible to have distinct ideas of every particular thing, to retain its name, with its peculiar appropriation to that idea.

Secondly, It would be useless, unless it could be supposed to have these same ideas in their minds: for names applied to particular things, whereof I alone have the ideas in my mind, could not be significant.

or intelligible to another, who is not acquainted with all those particular things which have fallen under my notice.

Thirdly, It would be of no great use for the improvement of knowledge; which, though founded in particular things, enlarges itself by general views; to which things, reduced into sorts under general names, are properly subservient.

In things where we have occasion to consider and discourse of individuals and particulars, we use proper names: as in persons, countries, cities, rivers, mountains, &c. Thus we see that jockeys have particular names for their horses, because they often have occasion to mention this or that particular horse, when he is out of sight.

Afterwards, observing that a great many things resemble each other in shape, and other qualities, we frame a general idea that takes in only the qualities in which those many particulars agree; and to this idea we give the name, *man*, for example, in which there is nothing new; that which is peculiar to each individual being left out, and only what is common to all retained. And thus we come to have a general idea, and a general name. By the same method the mind proceeds to more general notions and names, as those of animal, substance, being, thing, and such universal terms as stand for any ideas whatsoever.

As to the signification of general words, it is evident they do not barely signify one particular thing; neither do they signify a plurality. But they signify a genus, kind, or sort of things. See the articles ABSTRACTION and GENUS.

GENERAL of an Army, in the art of war, he who commands in chief. See ARMY.

A general ought to be a man of great courage and conduct, to have great experience, and to be of good quality. His conduct appears in establishing his magazines in convenient places; in examining the country, that he may not engage his troops too far, while he is ignorant of the means of bringing them off; in subsisting them; and in knowing how to take the most advantageous posts, either for fighting or shunning a battle. His experience inspires his army with confidence, and an assurance of victory; and his quality, by creating respect, augments his authority. By his liberality he gets intelligence of the strength and designs of the enemy, and by this means is enabled to take the most successful measures. A general ought likewise to be fond of glory, to have an aversion to flattery, to render himself beloved, and to keep a strict discipline.

The office of a general is to regulate the march and encampment of the army; in the day of battle to chuse out the most advantageous ground; to make the disposition of the army; to post the artillery; and where there is occasion, to send his orders by his aids de camp. At a siege he is to cause

the place to be invested; to order the approaches and attacks; to visit the works; and to send out detachments to secure his convoys.

GENERAL is also used for a particular march, or beat of drum; being the first which gives notice, commonly in the morning early, for the infantry to be in readiness to march.

GENERATING Line, or *Figure*, in geometry, is that which by its motion produces any other plane or solid figure. Thus, a right line moved any way parallel to itself, generates a parallelogram; round a point in the same plane, with one end fastened in that point, it generates a circle. One entire revolution of a circle, in the same plane, generates the cycloid; and the revolution of a semi-circle round its diameter, generates a sphere, &c. See the articles CYCLOID, SPHERE, &c.

GENERATION, *Generatio*, in physiology, the act of procreating and producing a thing which before was not; or, according to the schoolmen, it is the total change or conversion of one body into a new one, which retains no marks of its former state. Thus, we say, fire is generated, when we perceive it to be where before there was only wood, or other fuel: in the same manner a chick is said to be generated, when we perceive it where before there was only an egg; or the egg is changed into the form of a chick.

In generation, there is not properly any production of new parts; but only a new modification, or manner of existence, of the old ones.

When almighty God, says Dr. Blair, created the world, he so ordered and disposed of the *materies mundi*, that every thing produced from it should continue so long as the world should stand. Not that the same individual species should always remain; for they were in process of time to perish, decay, and return to the earth from whence they came; but that every like should produce its like, every species produce its own kind, to prevent a final destruction of the species, or the necessity of a new creation. For which end, he laid down certain regulations, by which each species was to be propagated, preserved, and supported, till, in order and course of time, they were to be removed hence: for without that, those very beings, which were created at first, must have continued to a final dissolution of all things; which almighty God of his infinite wisdom, did not think fit. But that he might still the more manifest his omnipotence, he set all the engines of his providence to work, by which one effect was to produce another, by means of certain laws or rules, laid down for the propagation, maintenance, and support of all created beings. This his divine providence is called nature, and these regulations are called the laws or rules of nature, by which it ever operates in its ordinary course; and whatever recedes from that, is said to be preternatural, miraculous, or monstrous.

GENERATION of Animals.—According to Aristotle, the males contain the principle, and the females the matter of generation: for though both were furnished, indeed, with a feminal liquor, yet the semen of the males alone was prolific. The moderns, on the other hand, as well those who contend for the system of generation from eggs, as they who adopt that of the animalcules in the male seed, pretend that females have no such feminal liquor at all, and that what was commonly taken for it was some other animal fluid.

There are great and many difficulties which attend the most plausible account of the first formation of the parts of an animal, and the beginning of motion in its fluids: for though both reason and experience convince us, that all the parts of an animal did exist before generation, yet, how this matter comes to assume so very different a form, as that of an embryo, is by no means agreed on.

Harvey is of opinion, that all females are furnished with eggs, and that the embryos, or young animals, are formed in the same manner as a chick in the egg of any bird. Generation, according to this celebrated physician, is effected only by means of the uterus, or womb, which conceives the foetus by a kind of contagion communicated to it by the male seed, much in the same way as a load-stone communicates magnetism to iron. This contagion, he thinks, acts not only on the uterus, but is communicated to the whole body of the female, which is altogether prolific; though the uterus he acknowledges is the only part that is capable of conceiving the foetus, just as the brain is alone capable of forming ideas and notions. Agreeably to this doctrine of Harvey, Steno, and other anatomists, have pretended to discover certain eggs in the ovaries or testicles of women; which Mr. Buffon denies to be the case, affirming, that there are no such eggs to be found in the testicles or ovaries of women.

We cannot enter into a detail of the reasonings for and against the system of generation from eggs, and shall therefore only observe, that its advocates pretend to have discovered eggs in all the females on which they made observations; that the largest of those found in women did not exceed the bigness of a pea; that they are extremely small in young girls under fourteen, but that age and commerce with men makes them grow larger; that there are more than twenty such eggs in each ovary or testicle; that they are fecundated in the ovary by the spirituous and volatile part of the male seed; that they afterwards are detached and fall into the uterus through the Fallopian tubes; that here the foetus is formed of the internal substance of the egg, and the placenta of the exterior part. See the article **Fœtus**.

Leewenhoek is the author of another system of generation, from animalcules in the male seed. He

tells us, he discovered many thousands of these in a drop less than a grain of sand. These are found in the semen of all males whatever, but not in that of females; and are so small, that 3,000,000,000 of them are not equal to a grain of sand, whose diameter is but the hundredth part of an inch. When any of these animalcules gets into an egg, fit to receive it, and this falls into the womb through the Fallopian tubes, the humous which distil through the vessels of the womb, penetrating the coats of the egg, swell and dilate it, as the sap of the earth does seed thrown into it. The placenta begins to appear like a little cloud, upon one side of the external coat of the egg; and, at the same time, the spine of the embryo-animalcule is grown so big, as to become visible; and a little afterwards, the cerebrum and cerebellum appear like two bladders; and the eyes stand next goggling out of the head; then the beating of the heart, or *punctum saliens*, is plainly to be seen; and the extremities discover themselves last of all.

The animalcules are of different figures, some like tadpoles, and others like cells. In the semen of a man, and in that of a dog, there have been discovered two different kinds of them, the one supposed to be males, and the other females. Some even pretend to have seen animalcules disengage themselves from the membranes that surround them; and that they then appeared perfectly like men, with legs, arms, &c. like those of the human body.

All the advocates for the system of generation from animalcules strongly oppose that from eggs. They contend, that these animalcules cannot be looked upon as the inhabitants of the semen, since they were of greater extent than the liquor itself, not to mention that no such animals are found in any other liquors of the body; and since females have nothing similar to these animals, they think it manifest that the prolific principle resides in the males. When they are asked, to what purpose serves such an immense profusion of human animalcules, they answer, that it is agreeable to the ordinary course of nature, both in the animal and vegetable part of the creation. They likewise strengthen their system, by alledging the many examples we have of similar transformations in the insect-class of animals, which from caterpillars and small worms, become winged animals of the butterfly, or fly-kinds.

By this system, says Mr. Buffon, the first woman cannot be said to have contained the whole race of mankind, as being all, according to it, the true posterity of the first man, and in their animalcule-state contained only in him. On this principle he proceeds to invalidate the system of generation from animalcules: for supposing the size of a man to be 1, then will that of one of the spermatic animalcules be $\frac{1}{1000000000}$; and as a man is to an ani-

G E N

Venus Physique. He observes, that all the variety, observable among mankind, may have been accidental at first; but being once established in the constitution of the parents, they become natural to their posterity. To illustrate this, he gives an instance of a sexdigitary family at Berlin, who had six fingers, or six toes, and frequently both; and that this peculiarity was transmitted equally by the father and mother, but was lost by alliances with those who had but the usual number of fingers or toes.

Those who desire a more full account of these systems of generation may consult Harvey, Leewenhoek, Buffon, &c.

Parts of GENERATION. The parts of generation, in men, are the testicles, vasa deferentia, vesiculæ seminales, and penis. See the article TESTICLE, &c.

Those, in women, are the pudendum or vulva, the clitoris, nymphae, vagina, uterus or womb, ovaries, and Falopian tubes. See the articles PUDENDUM, CLITORIS, &c.

GENERATION OF *Fishes*. The opinion of most naturalists, that the female fishes first deposit their spawn, and that the males afterwards eject the semen upon it, is denied by Linnæus; who thinks it impossible that the eggs of any animal should be impregnated out of its body. He thinks it much more probable, that the males always eject their semen some time before the females deposit their spawn; and that, by swallowing this semen, the spawn is impregnated in the body of the fish. Nay, he tells us, that he himself saw three or four females, in the spawning time, gather about the male, and greedily swallow the semen he ejected. This he observed in some species of the eelox, perch, and especially the cyprinus; but he recommends farther enquiry to be made on this subject.

GENERATION of *Insects* is now certainly known to be from eggs; which the female deposits in places, where, at a proper season, they are hatched into animals like their parents; or into maggots, or worms, which, after several transformations, at last appear in the form of their parents.

GENERATION of Plants. The impregnation of the female palm-tree by the male, has been known in the most ancient times. Herodotus, the father

As to Buffon's own system, he thinks that every part, both of animals and vegetables, contains an infinite number of organic molecules; that these molecules assume successively different forms, and are put into different motions, according to the circumstances they are in; but that they are much more numerous in the seminal liquors of both sexes, and the seeds of plants, than in other parts; that these organic molecules make the matter of nutrition; that this matter is always active, and tends to organization, forming itself into different shapes, according to the moulds it meets with. When the quantity of this organic matter is but small, as in man, and most large animals, generation only takes place at the age of maturity, and even then the number of animals produced is but small. The case is just the reverse in animals which abound with this matter, as in fishes, and most birds.

With respect to the generation of mankind, the same author thinks it a certain fact, that the male-feed is received into the womb of the woman; and that, for this purpose, it is highly probable the internal orifice opens during the act of coition. The female-feed also makes its way into the womb, where being mixed with that of the male, they both together contribute to the formation of the fœtus; which is either male or female, according as the seed of the man or woman abounds most with organic molecules; and the infant resembles either the father or mother, according to the different combinations of these molecules. Both these seminal liquors he thinks equally active in the formation of the fœtus and that they fix and counterbalance each other; the molecules of each parent being thereby determined to form similar parts to those of the individual that furnished them, as the head, trunk, arms, legs, &c. He thinks the molecules proceeding from the genital parts fix themselves first; and that the other molecules arrange themselves successively round these, in the same order which they before occupied in the parent. When a great quantity of the seminal liquors of both sexes is received into the womb, there are formed different spheres of attraction in different parts of these liquors; the consequence of which is, that several fœtuses are formed at the same time. See VEGETATION.

Nearly a-kin to Mr. Buffon's system is that of Mr. Maupertuis, which he has explained in his

GNOMON, in dialling, is the style or pin of a dial, whose shadow serves to point out the hour.

The word is Greek, and derived from *γνωμων*, which imports somewhat that makes known; because the style indicates the hour.

The gnomon of every dial is supposed to represent the axis of the world, and therefore the two ends, or extremities thereof, must answer to the north and south poles.

GNOMON, in geometry. If a parallelogram be divided into four lesser ones by two right lines drawn respectively parallel to the sides thereof, and one of these parallelograms be retrenched, or taken away; the remaining three will form a gnomon.

GNOMON, in astronomy, a pillar, &c. erected to find meridian altitudes of the sun and stars by its shadow.

The method of finding the sun's meridian altitude by the help of a gnomon was much used by the ancients. It must be observed, that the greater the height of the sun is, the shorter is the shadow of a gnomon, and the contrary. In making observations for determining the meridian altitudes of the sun and stars, it was usual to set down what proportion the length of the shadow bore to the height of the pillar; that is, the height of the pillar being divided into a certain number of equal parts, to say how many of these parts the length of the shadow amounted to at the equinoxes or solstices. The most ancient observation of this kind, that we meet with, is that made by Pytheas, in the time of Alexander the Great, at Marseilles, where he found the height of the gnomon was to the meridian shadow, at the summer solstice, as $213\frac{1}{2}$ to 600; the same as Gassendus found it to be, by an observation made at the same place, almost 2000 years after, in the year 1636.

A very exact method whereby to observe the meridian altitude of the sun is as follows.—Make a circular perforation in a brass plate, to transmit enough of the sun's rays to exhibit his image on the floor: fix this plate parallel to the horizon in a high place proper for observation: then let fall a plumb-line, whereby to measure the height of the perforation above the floor. Take care the floor be perfectly level, and exactly horizontal; and let it be whitened over, to exhibit the sun more distinctly: draw a meridian line thereon, passing through the foot of the gnomon, that is, through the point where the center of the plumb-line marks the floor: note the extreme points of the sun's diameter on the meridian line K and I (Plate LX. fig. 5.) and from each subtract a right-line equal to the semi-diameter of the aperture, viz. KH on one side, and LI on the other: then will HL be the image of the sun's diameter, which, bisected in B, gives the point on which the rays fall from the center of the sun.

Now having given the right-line AB, and the

altitude of the gnomon, with the angle A, which is right; the angle ABG, or the apparent altitude of the sun's center, is easily found: for assuming one of the given sides AB for radius; AG will be the tangent of the opposite angle B. Then say, as one leg AB: is to the other AG:: so is the whole sine: to the tangent of the angle B.

GNOMONICS, *Gnomonica*, the art of dialling, or of drawing sun and moon dials, on any given plane. See the article **DIAL**.

GNOSTICS, in church-history, christian heretics so called, it being a name which almost all the ancient heretics affected to take, to express that new knowledge and extraordinary light to which they made pretensions; the word gnostic signifying a learned, or enlightened person.

St. Epiphanius ascribes the origin of the Gnostics to Simon Magus, and says that they acknowledged two principles, a good and a bad. They supposed there were eight different heavens, each of which was governed by its particular prince: the prince of the seventh heaven, whom they named Sabaoth, created the heavens and the earth, and six heavens below him, and a great number of angels. In the eighth heaven they placed their Barbelo, or Barbero, whom they sometimes called the father and sometimes the mother of the universe. All the Gnostics distinguished the creator of the universe from God, who made himself known to men by his Son, whom they acknowledged to be the Christ. They denied that the Word was made flesh; and asserted that Jesus Christ was not born of the Virgin Mary, that he had a body only in appearance, and that he did not suffer in reality. They neither believed a resurrection, nor a judgment to come; but imagined that those who had not been instructed in their maxims, would return into the world, and pass into bodies of hogs and other of the like animals. They had several apocryphal books, as the Gospel of St. Philip, the Revelations of Adam, the Gospel of Perfection, &c.

GOAT, *Capra*, in zoology, a quadruped of the order of the pecora. See the article **CAPRA**.

GOAT'S-BEARD, *Tragopogon*, in botany. See the article **TRAGOPOGON**.

GOAT'S-EYE, *Egias*, among ancient physicians. See **ÆGIAS**.

GOAT-SUCKER, *Caprimulgus*, in ornithology, a species of hirundo. See **HIRUNDO**.

GOAT'S-THORN, the same with tragacanth.

GOBELINS, a celebrated manufactory for tapestry, established by Mr. Colbert, at Paris, in 1667. See **TAPESTRY**.

GOBONE, or **GOBONY**, in heraldry, the same with componed. See **COMPONED**.

GOD, *Deus*, the Supreme Being, the first cause or creator of the universe, and the only true object of religious worship.

The Hebrews called him Jehovah; which name they never pronounced, but used instead of it the words Adonai, or Elohim.

God, says Sir Isaac Newton, is a relative term, and has respect to servants. It denotes, indeed, an eternal, infinite, absolutely perfect being: but such a being without dominion, would not be God. The word God frequently signifies lord, but every lord is not God. The dominion of a spiritual being, or lord, constitutes God; true dominion, true God; the supreme, supreme; pretended, pretended. From such true dominion it follows that the true God is living, intelligent, and powerful; and from his other perfections, that he is supreme, or supremely perfect. He is eternal and infinite, omnipotent and omniscient; that is, he endures from eternity to eternity, and is present from infinity to infinity. He governs all things that exist, and knows all things that are to be known. He is not eternity or infinity, but eternal and infinite. He is not duration and space, but he endures and is present: he endures always, and is present every where; and by existing always and every where, constitutes the very things we call duration and space, eternity and infinity. He is omnipresent, not only virtually, but substantially; for power without substance cannot subsist. All things are contained and move in him, but without any mutual passion, that is, he suffers nothing from the motions of bodies, nor do they undergo any resistance from his omnipresence.

With respect to Christians it will be sufficient to mention, that they were very early divided in opinion, with regard to the nature and essence of the Supreme Being; a great part worshipping three persons in the unity of the godhead, while others absolutely rejected a trinity of persons, and asserted the unity of the Divine nature, both with respect to person and substance.

GODDESS, a heathen deity of the female sex.

GOD-FATHERS and **GOD-MOTHERS**, persons who undertake to answer for the future conduct of infants at their baptism.

GOLD, *Aurum*, the sol and rex metallorum of the chemists, is a yellow metal scarce at all elastic or sonorous, very soft and flexible, the most ductile of all metallic bodies. Dr. Halley took one grain of gilt silver, of which only one forty-eighth part was gold: this grain was drawn into a wire two ells in length, which examined by a microscope, appeared every where covered with the gold: a piece of the wire being put into aqua-fortis, the silver was eaten out, and a tube of gold remained, which notwithstanding its extreme thinness, was still opaque.

Gold is of all natural bodies the most ponderous: hence it sinks into quicksilver, whilst all other substances, platina excepted, swim on the surface. It is upwards of nineteen times heavier than an equal

bulk of water: a Paris cubic foot is reckoned to weigh 1368 pounds. From its greater density it becomes sensibly hotter than other bodies when laid with them in hot water.

Gold dissolves in a mixture of the nitrous and marine acids, called, from its action on this rex metallorum, aqua-regia: either of these acids singly have no effect upon it; nor is it acted on by the vitriolic.

GOLD-WIRE, a cylindrical ingot of silver, superficially gilt, or covered with gold at the fire, and afterwards drawn successively through a great number of little, round holes, of a wire-drawing iron, each less than the other, till it be sometimes no bigger than a hair of the head. See the article **WIRE**.

GOLD-WIRE flattened, is the former wire flattened between two rollers of polished steel, to fit it to be spun on a stick, or to be used flat, as it is without spinning, in certain stuffs, laces, embroideries, &c. See the article **STUFF**, &c.

GOLD-THREAD, or **SPUN GOLD**, is a flattened gold, wrapped or laid over a thread of silk, by twisting it with a wheel and iron bobbins.

GOLD-LEAF, or **BEATEN GOLD**, is gold beaten with a hammer into exceeding thin leaves, so that it is computed, that an ounce may be beaten into sixteen hundred leaves, each three inches square, in which state it takes up more than 159052 times its former surface.

This gold they beat on a block of black marble, about a foot square, and usually raised three feet high: they make use of three sorts of hammers, formed like mallets, of polished iron: the first, which weighs three or four pounds, serves to chase, or drive: the second, of eleven or twelve pounds, to close; and the third, which weighs fourteen or fifteen pounds, to stretch and finish. They also make use of four moulds of different sizes, viz. two of vellum, the smallest whereof consists of forty or fifty leaves, and the larger of two hundred: the other two, consisting each of five hundred leaves, are made of bullocks guts well scoured, and prepared.

Method of preparing and beating GOLD. They first melt a quantity of pure gold, and form it into an ingot: this they reduce, by forging, into a plate about the thickness of a sheet of paper; which done, they cut the plate into little pieces about an inch square, and lay them in the first or smallest mould to begin to stretch them: after they have been hammered here a while with the smallest hammer, they cut each of them into four, and put them into the second mould, to be extended farther.

Upon taking them thence, they cut them again into four, and put them into the third mould, out of which they are taken, divided into four, as before, and laid in the last, or finishing mould, where they are beaten to the degree of thinness required.

The leaves thus finished, they take them out of the mould, and dispose them into little paper books, prepared with a little red bole for the gold to stick to; each of which ordinarily contains twenty-five gold leaves. There are two sizes of these books; twenty-five leaves of the smallest only weigh five or six grains, and the same number of the largest, nine or ten grains.

It must be observed, that gold is beaten more or less, according to the kind or quality of the work it is intended for; that for the gold wire-drawers to gild their ingots, is left much thicker than that for gilding the frames of pictures, &c. withal. See **GILDING**.

GOLD-FINCH, in ornithology, the English name of a species of fringilla, with the wings variegated with black, yellow, and white.

GOLD-SIZE. See the article **SIZE**.

GOLD-SMITH, or as some choose to express it, silver-smith, an artist who makes vessels, utensils, and ornaments in gold and silver.

Shell-GOLD, that used by the illuminers, and wherewithal we write gold letters. It is made of made of the pareings of leaf-gold, and even of the leaves themselves, reduced into an impalpable powder, by grinding on a marble with honey. After leaving it to infuse some time in aqua-fortis, they put it in shells, where it sticks. To use it they dilute it with gum-water, or soap-water.

GOLDEN, something that has relation to gold, or consists of gold, is valuable, or the like; as,

GOLDEN-BULL. See the article **BULL**.

GOLDEN-CALF, in Jewish antiquity, a figure which the Israelites cast in gold, and set up in the wilderness to worship during Moses's absence in the mount, and which that legislator, at his return, burnt, ground to powder, and mixed with the water the people were to drink of; as in Exod. xxxii.

GOLDEN-FLEECE, in the ancient mythology, the skin, or fleece, of the ram upon which Phryxus and Hella are supposed to have swam over the sea to Colchis; which being sacrificed to Jupiter, its fleece was hung upon a tree in the grove of Mars, guarded by two brazen-hoofed bulls, and a monstrous dragon that never slept; but was at last taken and carried away by Jason, and the Argonauts.

GOLDEN-NUMBER, in chronology, a number shewing what year of the moon's cycle any given year is. See **CYCLE of the Moon**.

GOLDEN-RULE, in arithmetic, is also called the rule of three, and the rule of proportion. See **PROPORTION** and **RULE of THREE**.

GOLDEN-ROD, in botany. See the article **SOLIDAGO**.

GOLDEN-SAXIFRAGE. See the article **CHRYSOPTERUM**.

GOLPS, in heraldry, are roundles of a purple tincture, called by the French *torteaux*, adding their peculiar colours.

GOMPHOSIS, γομφωσις, in anatomy, a species of articulation, wherein one bone is set in the other, like a nail or peg; as the teeth within the jaws.

GOMPHRENA, the purple everlasting flower, in botany, a genus of plants, the flower of which is divided into five parts, and erect; the petals are subulated and permanent: the fruit is a thin, roundish crust, with one cell, in which are contained a single, large, roundish seed, with an oblique end. It is a native of both East and West-Indies; and the flower is usually of a beautiful purple colour.

GONDOLA, a sort of barge curiously ornamented, and navigated on the canals of Venice. See the article **BARGE**.

GONORRHOEA, in medicine, an involuntary efflux of the seminal juices, and some other recrementitious matter.

A virulent gonorrhoea, or clap, proceeds from impure coition with an infected person.

This distemper begins, and makes its progress, in the following manner.

The patient, sooner or later, according as the person with whom he has had conversation, was more or less infected, and according to his constitution, by which he may be more or less disposed to receive the infection, is first seized with an unusual pain in the genitals; and a kind of sensation like a rotation of his testicles. Afterwards, if the prepuce constantly covers his glands, there appears an eruption, or pustule, which, by its size, colour, and figure, resembles a spot of the measles. Presently after appears a weeping matter like semen, which daily changes colour, and becomes more purulent, and more yellow, till at length, if the disorder be highly virulent, it assumes a greenish hue, or appears like a thin sanious matter, mixed with blood. The pustule at length becomes an ulcer, called a shanker.

Those whose glans is uncovered, seldom have such a pustule, and are less liable to imbibe the infection. The running brings on a heat, or smarting in making water, which is most violent when it is over, for then it seems to burn the whole duct of the urethra.

Another symptom is the cordee, or contraction of the frænum, by which the penis is bent downwards. There is likewise, when the penis is erected, great pain, as if compressed transversely with a strong hand. This chiefly happens in the night, when the patient is warm in bed: sometimes the urethra being eaten, and excoriated with long running of acrimonious pus, nature breeds a soft spungy flesh, to supply the defect; which daily increasing, forms caruncles, or carnosities so far as to plug up the urinary passage, and stop up the urine. However, the little adjoining ulcers continue to pour forth a kind of an ichor. It also happens, through some violent motion, or the ill-timed use of astring-

astringents, that the sanies, which should be carried off by the gonorrhœa, is translated to the scrotum, and causes one or both of the testicles to swell, and inflame with intolerable pain : the running at the same time decreasing, while the scalding of the urine is as great as ever.

To these symptoms may be added the phimosis, and the paraphimosis. There are also sometimes watery bladders, called crystallines, and at length buboes of the glands in the groin. See PHIMOSIS, PARAPHIMOSIS, BUBO, and POX.

Women are not subject to such a variety of symptoms as men; their chief complaint being a difficulty of urine, and a running; however, they are liable to shankers and venereal warts, as well within as on the outward parts of the labia pudendi; as also to buboes in the groin: as for the contraction of the sphincter vaginæ, purring as it were the external orifice, this is not a phimosis, though by some improperly so called.

This disorder proceeding from an infection of a malignant gonorrhœa, or the lues venerea, is first conveyed to the genitals, and afterwards through the pores to the lymph, or seminal liquor; the due crasis and natural mixture of which it destroys, by inducing partly a caustic and corroding, and partly a putrid state thereof; hence arise the pains, the heats, the tumours, the inflammations, and the excruciations of the genitals: for at first the glands only is infected whilst in coition, the poison insinuating itself into the pores; after which, it soon proceeds to the glands of the urethra, then to the prostates, and afterwards to the vesiculæ seminales.

Astruc, in the cure of this disorder, directs the use of crude quicksilver, as in the common unction, to be rubbed upon the parts, as about the penis, especially under the urethra, to the perinæum, and so up to the pubes and testicles, by which the mercury, insinuating itself through the pores into the lymphatic vessels, is instantly conveyed into the glandules, and subdues the poison lodged therein, taking away all the symptoms without any disturbance to the primæ viæ, the stomach and guts.

If there is no discharge from the penis of any virulent matter, it is called the gonorrhœa sicca, or dry clap; the symptoms of which are a dysury, or difficulty of making water, and after, from the increase of the inflammation and tumefaction, an ichthy, or total suppression of urine.

In the cure of the dry clap, Astruc advises plentiful bleeding in the beginning, to take off the tension, and to abate the inflammation; as also emollient decoctions of mallows, linseed, &c. in milk, to foment the parts: but perhaps it might be better to make a poultice of these ingredients, after Boerhaave's method, to lay to the parts affected; or, which is best of all, to use them one after the other.

Astruc advises also lenient clysters, cooling emulsions, and pitans, with sal prunella and anodynes, between whites. During the continuance of the inflammation, no mercurials must be used, and if the symptoms increase, threatening an abscess in the perinæum, it is to be forwarded as much as possible, by suppurative poultices, and the matter discharged.

When the gonorrhœa has continued a long while, or long enough for the poisonous matter to make its way into the blood; or by astringents given unseasonably it cannot make its exit; then the patient is infected with the pox.

The third species of this disorder requires the very same treatment with the simple and virulent: but here the least time must not be lost; the affected part must be kept in a constant state of laxity, by the most emollient applications; and the contagious matter must with all possible expedition be drawn out: for the whole cure depends upon the total discharge of the infectious matter, together with the pus, which it has introduced; and if this task is not performed, a pox is greatly to be apprehended. Wherefore, if this disease continues but for a little time, recourse must be had to all the severities of a salivation. For though salivating does not at all cure either of the two former kinds of gonorrhœa, this species of the disease, having its seat in the glandulæ Cowperianæ of the urethra, so that the pus discharges itself by their excretory duct into the urinary duct, is much more susceptible of the power of mercury.

GOOD, in general, whatever is apt to cause or increase pleasure, or diminish pain in us; or, which amounts to the same, whatever is able to procure, or preserve to us the possession of agreeable sensations, and remove those of an opposite nature.

Metaphysical GOOD, the same with perfection. See PERFECTION.

Moral GOOD, denotes the right conduct of the several senses and passions, or their just proportion and accommodation to their respective objects and relations.

GOOD BEHAVIOUR, in law, an exact carriage and behaviour to the king and his people.

GOOGINGS, in ship-building, certain plates of iron bolted to the stern-post of a ship, to receive and keep steady the rudder.

There are four or five of them on the stern-post, having a large hole in each, into which certain spindles, called pintles, are introduced, upon which the rudder rests, and turns as upon an axis. See the article RUDDER.

GOOSE, *Anser*, in ornithology, a well-known bird of the anas-kind, with the back of a greyish brown colour, the belly and edges of the wing-feathers white.

GOOSEBERRY, *Grossularia*, in botany, a genus of plants of the shrub kind; its characters are,

it hath a woody root, the branches when full grown are of a dark purple colour, armed with sharp thorns at the rise of the leaves, which have short pedicles, and are lacinated like those of the currant or vine, but less; the flowers are like those of the currant, with which Linnæus classes them, under the general names ribes, but as they differ much both in their appearance and also their fruit, which in this grow not in bunches, it may here be thought proper to separate them as distinct genera. There are several sorts of gooseberries propagated in gardens, as the amber-gooseberry, red hairy gooseberry, large Dutch gooseberry, green gooseberry, red smooth gooseberry, with some other varieties; they are all propagated by cuttings, suckers, or from seeds, though best from cuttings, which may be taken off in autumn or spring; they are managed much the same as the currant both in planting and pruning, excepting that the extremities are commonly left in pruning.

GOOSE-NECK, among sailors, a sort of hook fixed in the inner end of a boom, or pole, to extend the bottom of some of the sails of a ship, particularly the main boom of a brig or sloop, and the lower-studding-sail booms of ships and larger vessels. See the article **BOOM**.

The goose neck is hooked in a ring or eye-bolt of iron, and may be occasionally unhooked at pleasure.

GOOSE-WINGS of a *Sail*, the clues, or lower corners, of a ship's main-sail or fore-sail, when the middle part is tied up or furled to the yard.

The goose-wings are only used in a great storm to furl under, when the sail at large, or even reefed, would be too much for the ship to carry at such a time.

GOR-COCK, a bird, otherwise called a moor-cock. See **MOOR-COCK**.

GORDIAN KNOT, in antiquity, a knot made in the leathers or harness of the chariot of Gordias, king of Phrygia, so very intricate, that there was no finding where it began or ended.

The inhabitants had a tradition, that the oracle had declared, that he who untied this knot, should be master of Asia. Alexander having undertaken it, was unable to accomplish it, when fearing lest his not untying it should be deemed an ill augury, and prove a check in the way of his conquests, he cut it asunder with his sword, and thus either accomplished or eluded the oracle.

GORE, in heraldry, one of the abatements, which, according to Guillim, denotes a coward. It is a figure consisting of two arch lines drawn one from the sinister chief, and the other from the sinister base, both meeting in an acute angle in the middle of the fess point.

GORE, in law, signifies a narrow slip of ground.

GORGE, *Gula*, in architecture, the narrowest

part of the Tuscan and Doric capitals, lying between the astragal, above the shaft of the pillar and the annulets. See **TUSCAN** and **DORIC**.

It is also used for a concave moulding, larger, but not so deep as a scotia, which serves for compartments, &c. See the article **COMPARTMENT**.

GORGE, in fortification, the entrance of the platform of any work.

In all the outworks, the gorge is the interval betwixt the wings on the side of the great ditch, as the gorge of a ravelin, half-moon, &c. These, it is to be observed, are all destitute of parapets; because, if there were any, the besiegers, having taken possession of the work, might use it to defend themselves from the shot of the place; which is the reason that they are only fortified with palisadoes, to prevent a surprize.

The gorge of a bastion is nothing else but the prolongation of the curtains from their angle with the flanks, to the center of the bastion where they meet. When the bastion is flat, the gorge is a right line, which terminates the distance between the two flanks. See the articles **BASTION** and **FORTIFICATION**.

GORGED, in heraldry, the bearing of a crown, coronet, or the like, about the neck of a lion or swan, and in that case it is said, the lion or cygnet is gorged with a ducal coronet, &c.

Gorged is also used when the gorge, or neck of a peacock, swan, or the like bird, is of a different colour or metal from the rest.

GORGED, among farriers, &c. signifies the same as swelled; in which sense they say, the legs of a horse are gorged; the pastern joint is gorged; you must walk him out to disgorge his shoulder.

GORGERIN, in architecture, the same with gorge. See the article **GORGE**.

GORGONS, in antiquity, a warlike female nation of Lybia, in Africa, who had frequent quarrels with another nation of the same sex, called Amazons.

GOSHAWK, the English name of a yellow-legged falcon, with a brown back, and a white variegated breast.

GOSPEL, the history of the life, actions, death, resurrection, ascension, and doctrine of Jesus Christ.

This history is contained in the writings of St. Matthew, St. Mark, St. Luke, and St. John; who from thence are called evangelists. The Christian church never acknowledged any more than these four gospels as canonical; notwithstanding which, several apocryphal gospels are handed down to us, and others are entirely lost.

GOSSYPIMUM, cotton, in botany, a genus of plants whose flower consists of five plane patent petals, growing together at their bases, and vertically cordated; the stamina are numerous, and joined in a column, and the fruit is a roundish capsule containing

aining four cells, which encloses a number of oval seeds, surrounded with a downy matter called cotton. See the article COTTON.

GOTHIC, in general, whatever has any relation to the Goths; thus we say, Gothic customs, Gothic architecture, &c. See the article ARCHITECTURE.

Gothic architecture is far removed from the manner and proportions of the antique; having its ornaments wild and chimerical, and its profiles incorrect: however, it is frequently found very strong, and appears very rich and pompous, as may be seen in several of our English cathedrals. This manner of building was, originally, very heavy and coarse; but is since run into the opposite extreme, being slender, rich, and delicate to a fault. In the Gothic architecture we see high vaults raised on slender pillars; and every thing crowded with windows, roses, crosses, figures, &c.

GOVERNMENT, in general, is the polity of a state, or an orderly power constituted for the public good.

GOVERNMENT is also a post or office which gives a person the power or right to govern or rule over a place, a city or province, either supremely or by deputation.

GOVERNMENT is also used for the city, country, or place to which the power of governing is extended.

GOVERNMENT, in grammar, a part of construction usually called regimen.

GOUGE, an instrument or tool used by divers artificers; being a sort of round hollow chisel, for cutting holes, channels, grooves, &c. either in wood or stone. See JOINERY.

GOURD, *Cucurbita*, in botany. See the article CUCURBITA.

GOUT, *Arthritis*, in medicine, as defined by Boerhaave, a very painful disease, whose seat is in the joints and ligaments of the feet, and whose principal times of invasion are the spring and autumn.

The curative intention, according to Winingham, requires, first, that the primæ viæ be set free from a load of indigested crudities, and the viscera be restored to their pristine vigour; secondly, that the fluid stagnating in, and stuffing up the smaller vessels, may be expelled the body, and a free passage through the contracted vessels be restored.

The first intention may be answered by vomits and gentle cathartics repeated as occasion requires; by bitters, aromatics, antiscorbutic medicines; by alkaline fixed salts, taken in small quantities for a long time; by aliments and drinks that are nourishing, light, easy of digestion, quickly assimilated, and taken in due quantity; by powerful exercise often repeated, and long continued; and especially by riding in a dry, serene, pure air; by frictions; by motion of the affected parts; by going to sleep at early hours.

The second intention may be answered partly by the preceding, as well as by procuring gentle sweats; by bathing in natural and artificial baths; by sweating in a bagnio; or by the use of volatile salts, and copious drinking of attenuating liquors, actually hot, in the morning while in bed, in order to procure a sweat; as also by mercurial purges, taking a large quantity of diluents after them; by frictions of the whole body, especially the parts affected, with hot, dry, linen-cloths, till a redness appear; by cold baths, and the like.

To abate the excessive pain in the part affected, Boerhaave says, that if there be an absolute necessity, opiates may be given internally, and the patient may drink plentifully of hot whey, or any other liquor of the like nature. Externally emollients and anodynes may be used, laid on pretty hot; or the part affected may be beat with nettles; or it may be appointed with terebinthinated balsam of sulphur; or tow may be burnt thereon.

GOUT-WORT, in botany, a term sometimes used for angelica. See ANGELICA.

GOUTY-LAND, among farmers, denotes a moorish, cold, and black soil, abounding with springs.

In Staffordshire, this sort of land is ordered much in the same manner as heathy land, only that it is usually burnt deeper. It bears little but oats, white oats upon the gouty, and black oats upon the black cold land.

The turf of these grounds burnt, and carried upon rye or barley lands, is esteemed a better improvement than dung. See the article HEATHY LAND.

GRACE, *Gratia*, among divines, signifies any unmerited gift which God bestows on mankind.

Act of GRACE, an act of parliament for a general and free pardon, and for setting at liberty insolvent debtors.

Days of GRACE, in commerce. See DAY.

GRACES, in heathen mythology, three goddesses, whose names were Aglaia, Thalia, and Euphrosyne; that is, shining, flourishing, and gay; or, according to some authors, Palsithea, Euphrosyne, and Ægiale. Some make them the daughters of Jupiter and Eurynome, or Eumonia, the daughter of Oceanus; but the most common opinion is, that they were the daughters of Bacchus and Venus.

They are sometimes represented dressed, but more frequently naked, to shew, perhaps, that whatever is truly graceful, is so in itself, without the aid of exterior ornaments. They presided over mutual kindness and acknowledgement; bestowed liberality, eloquence; and wisdom, together with a good grace, gaiety of disposition, and easiness of manners.

GRACILIS, in anatomy, a muscle of the leg, so called from its slenderness: it arises from the synchondrosis of the os pubis.

GRADATION, in general, the ascending step by step, or in a regular and uniform manner.

GRADATION, in architecture, a flight of steps, particularly ascending from the cloister to the choir in churches.

It also denotes an artful disposition of several parts, as it were by steps and degrees, after the manner of an amphitheatre; so that those placed before, are rather serviceable than the contrary, to those behind.

GRADATION, in painting, a gradual and insensible change of colour, by the diminution of the tints and shades.

GRADATION, in rhetoric, the same with climax. See the article **CLIMAX**.

GRAFT, or **GRAFF**, in gardening, a cion or shoot of a tree inserted into another, so as to make it yield fruit of the same nature with that of the tree from whence the graft was taken.

GRAFTING, or **ENGRAFTING**, is the taking a shoot from one tree, and inserting it into another, in such a manner, that both may unite and form one tree.

There are various methods of grafting; but the following will be sufficient to explain the manner of performing the operation; which is done about the latter end of March, or the beginning of April:

The top of the stock is cut off in a smooth, straight place; then the cion, or graft, is prepared by cutting it on one side from the joint, or seam, down slopewise, making the slope about an inch, or an inch and an half long; and observing it is bent so that the cion may stand nearly upright when it is fixed to the stock. At the top of the slope a shoulder is made, whereby it is to rest on the crown of the stock. The whole slope must be plain and smooth, that it may lie even to the side of the stock. The length of the cion used here may be about four inches from the shoulder, for a standard tree; but for a dwarf, or wall tree, it may be six inches.

When the cion is prepared, the outside of its sloped end, from the shoulder downwards, is applied to the west, or south-west side of the stock, and its length and breadth measured thereon; which done, the bark of the stock (but not any of its wood) is cut away to those dimensions, that the cut part of the cion may be fitted in as exactly as possible. In doing this, regard must be had to the bigness of the stock, and the thickness of its bark, in order to proportion thereto the length and breadth of the cut part of the cion; otherwise the passages of the sap in the stock and cion will not meet, and the cion will then of course perish. When the cut part of the cion is exactly fitted to, and laid on that of the stock, they are bound together with woollen yarn, and covered with clay, an inch above and as far below the head of the stock; working it round the cion, till it become sharp at top, that the rain may run down it.

Whip-GRAFTING, or *Tongue-GRAFTING*, is proper for small stocks, from an inch diameter to a quarter of an inch, or even less. Mr. Worlidge, Mr. London, Mr. Miller, and others, speak of it as the most effectual way of any, and that which is most in use, because the cion covers the stock much sooner in this method than in any other; for here the cion and stock must always be of the same thickness. There are three ways of performing it, and all of them may be practised somewhat later than either of the foregoing.

The first is, to slope the cion off a full inch, or more; then to do the same to the stock; and afterwards to tie the one to the other, with bafs or yarn, so as to join them closely at every part, but particularly at the rind; and then to cover the joint carefully with well-tempered clay. The bafs used for this, or for any other binding, should be taken from a found mat, and be soaked in water for some hours, to increase its strength, and render it the more pliable.

The second way is, to make a shoulder in the graft, and, the head of the stock being cut off and smoothed, to join it.

The third method, which is an improvement of the last, is properly named tipping or tonguing. This is done by cutting the stock off slanting, as before, and leaving at its upper side a thin piece, or tongue, as it is called, of the wood, pared away like the lower end of a cion. The cion is then sloped, and tongued, in the same manner as the stock, and a slit is made in each of them, downward in the stock, and upward in the graft, on the side opposite to the tongue, so that each may receive the tongue of the other. The cion is then joined to the stock, as closely as can be, particularly at the bark; a ligature is made round them with bafs or woollen yarn, and the engrafted part is well covered with clay or cement.

Root-GRAFTING, is a modern invention, the design of which is somewhat different from that of any of the former methods; this being for the propagation or multiplication of plants already fitted to produce their fruit.

To perform this, take a graft, or sprig, of a young tree, which you intend to propagate, and a small piece of the root of another tree of the same kind, or of a like genus, and whip-graft them together; observing that the butt-ends of the graft and root be well united, and that the rind of the root join closely to that of the graft. These may, afterwards, be planted out at pleasure, and the piece of root will collect the nutritive juices, and feed the graft, as the stock does the other way.

This method of propagation is very easy and expeditious; roots being more plentiful than stocks: by this means the pieces of roots of one crab-stock, for example, or of one apple-stock, will serve for twenty or thirty apple-grafts; and the like of other trees.

trees. It is also an excellent way for raising tender trees, which will hardly bear being grafted in the stock. Add, that trees thus grafted bear sooner, and are more easily dwarfed, than any other way.

The only objection against this method is, that the young tree grows but slowly at first, which is occasioned by the smallness of the root that feeds the graft; for in all trees the head must follow the increase of the roots, from whence it hath its nourishment.

Reiterated-GRAFTING, or *GRAFTING by a double, or triple Incision*, is a method mentioned by Agricola; whose work, though chimerical enough in many respects, contains, notwithstanding, several good things. To perform this, first graft a good cion on a stock, and cut it away to one-half, or a third part; then fix to that remaining part of the cion, another graft, of a better kind; and to that a third; for the oftener the tree is grafted, the finer fruit it produces.

By this method, the author above-mentioned assures us, that he produced muscat-pears, which were admirable; making, at first, use of a stock grafted with a pound-pear, on which he grafted a summer bon-chretien; and when the branch of this last had shot, he grafted on it a cion of a bergamo, which he also cut, and grafted on it a cion of a muscat-pear.

GRAFTING by Approach, called also *Inarching*, and *Ablatation*, is used only when the tree intended to be grafted, and that from which the graft is to be taken, stand so near, or can be brought so near to each other that they may be joined together. The method of performing it is thus: The branch to be inarched is fitted to that part of the stock where it is to be joined; the rind, and part of the wood, of one side of that branch, is then pared away very smooth and even, for the length of three inches; and afterwards, the other branch, which is to serve for the stock to which the graft is to be united, is served in the same manner, so that the two may join closely and equally together, that the sap vessels may meet. A little tongue is then cut upwards in the graft, and a slit is made in the stock, to receive it; so that when they are joined, the tongue prevents their slipping, and the graft is the more closely united to the stock. When they are thus placed exactly together, they must be tied with bass, worsted, or some other soft thing; and the place of junction must be well covered over with grafting-clay, to prevent the air from drying the wound, and the wet from rotting the stock. A stake must also be fixed in the ground, and both the stock and the graft must be tied thereto, to prevent their being displaced by the wind. When they have remained in this state four months, they will be sufficiently united, and the graft may then be cut off from the mother tree; observing to slope it close to the stock. It is of great service to the graft then to lay a fresh coat of

clay all round the grafted or jointed part. This operation should be performed in April or May, that the graft may be perfectly united to the stock, before the ensuing winter.

This method was more practised formerly than at present, on orange-trees, jasmines, &c. but as there are better ways to manage them, either by cuttings or inoculation, inarching is therefore little used, but on those sorts of plants which are of a firm contexture and slow growth, which will not take otherwise.

It may be remarked, that few trees will take on each other, unless they are of the same genus; for instance, a plumb cion will not take on a nut-tree, but an almond, peach, nectarine, or apricot cion, will take on a plumb stock, and *vice versa*; as they are all of the same family, and are therefore properly classed together by Linnæus under the general name *prunus*, as they agree in their generical characters, by which they are distinguished from all other trees; but many of these are very subject to emit large quantities of gum (if grafted by the afore-mentioned forms) from such parts of the trees as are deeply cut and wounded, which in the tender kinds, as peaches and nectarines, are more common and hurtful; it is found by experience, as the safest method, to practise escheueon-grafting, or, as it is more commonly called, inoculation. See the article *INOCULATION*.

The walnut, fig, and mulberry, will also take by this method of grafting, though neither of them will succeed in any other way: but still they, like all other trees thus managed, will remain weak, and stunted in their growth, besides the shortening of their otherwise usual time of duration.

All grafts, particularly of young cions, are subject to be injured by birds; but that may be prevented, by binding some small bushes about the tops of the stocks.

The binding of grafts should be loosened when the cions have pushed forth about an inch and an half, or two inches, for if it is continued longer, its too great tightness will hinder the swelling of the stock, so as to hazard the cion being broke by the winds at the place of bandage: as a substitute in this case, if the cion is so ordered in cutting, that an eye be left against the place of junction, between the stock and graft, there is a probability of the bud putting forth after the damage has so happened, provided it is broke off above it, and thereby a year is gained.

GRAIN, a general name for all sorts of corn, as wheat, barley, &c.

GRAIN, is also the name of a small weight, the twentieth part of a scruple in apothecaries weight, and the twenty-fourth of a penny-weight troy. See the article **WEIGHT**.

GRAIN also denotes the component particles of stones and metals, the veins of wood, &c. Hence cross-

cross-grained, or against the grain, is contrary to the fibres of wood, &c.

GRAINING-BOARD, among curriers, an instrument (called also a pummel) used to give a grain to their leather. See the article **CURRYING**.

GRAMEN, grass, in botany. See the article **GRASS**.

GRAMEN JUNCUM, a name used by Morison for a species of plantain.

GRAMINEOUS CROWN, in antiquity, the fame with the obsidional one. See the article **CROWN**.

GRAMINEOUS PLANTS, those with narrow, oblong leaves, without any pedicle; such are grasses, pinks, &c.

GRAMMAR, γραμματική, the art of speaking and writing any language with propriety.

GRAMMAR is also used for a book containing the rules of this art, methodically digested; of which there are multitudes indeed, but few good ones.

GRAMMARIAN, one that is skilled in, or teaches grammar.

GRAMMATICAL, in general, something belonging to grammar. See the article **GRAMMAR**.

GRANADIER, a soldier armed with a sword, a firelock, a bayonet, and a pouch full of hand-granadoes. They wear high caps, are generally the tallest and bravest fellows, and are always the first upon all attacks.

Horſe-GRANADIERS, called by the French *grenadiers volans*, or flying-granadiers, are such as are mounted on horseback, and fight on foot: their exercise is the same with the other granadiers.

GRANADILLA, passion-flower, a plant called by Linnæus *passiflora*. See the article **PASSIFLORA**.

GRANADO, a hollow ball or shell, of iron or other metal, about two inches and a half in diameter, which, being filled with fine powder, is set on fire by means of a small fusee fastened to the touch hole, made of the same composition as that of a bomb: as soon as the fire enters the shell, it bursts into many pieces, much to the damage of all that stand near. See the article **BOMB**.

Thuanus observes, that the first time grenadoes were used, was at the siege of Wachtendonck, a town near Guedres; and that the inventor was an inhabitant of Venlo, who, in making an experiment thereof, occasioned two-thirds of that city to be burnt, the fire being kindled by the fall of a granado.

GRANARY, a building to lay or store corn in, especially that designed to be kept a considerable time.

GRAND, a term borrowed from the French, implying the same with great.

GRAND-JURY, the jury who find bills of indictment at the sessions, &c. of the peace.

GRANGE, a house or farm furnished with gra-

naries and barns for holding corn, stables for horses, stalls for cattle, &c.

GRANIFEROUS POPS, among botanists, are such as contain small seeds resembling grain.

The word is compounded of the Latin, *granum*, grain, and *fero*, to bear.

GRANITE, *Granita*, in natural history, a distinct genus of stones, composed of separate and very large concretions, rudely compacted together, of great hardness, and capable of receiving a very beautiful polish.

GRANIVOROUS, in natural history, an epithet given to animals that feed on corn or seed.

The word is compounded of the Latin, *granum*, grain, and *vor*, to devour.

GRANULATION, in metallurgy, the action of reducing metals to small particles in order to promote their fusion and mixture with other bodies.

GRAPES, the fruit of the vine. See the article **VINE**.

GRAPE-HYACINTH. See the article **MUSCARI**.

GRAPHOMETER, among surveyors, an instrument for taking angles, and generally called a semi-circle. See **SEMI-CIRCLE**.

GRAPPLING, in the sea-language, a sort of small anchor with four or five flukes or arms, commonly used to ride a boat. See **ANCHOR**.

Fire GRAPLING, an instrument nearly resembling the above, only that it is fitted with strong barbes in the room of flukes; and is fixed at the yard arms of a fire-ship, to grapple her adversary, and set her on fire.

GRASS, *Gramen*, in botany, a general name for most of the herbaceous plants used in feeding cattle.

GRASS-PLATS, and green walks, are made, for the most part, not by sowing grass-seed, but by laying turfs; and, indeed, the turfs from a fine common, or down, are much preferable to sown grass: but if walks or plats are to be made by sowing, the best way is to procure the seed from those pastures, where the grass is naturally fine and clear, or else the trouble of keeping it from spiny or benty grass will be very great, and it will scarce ever look handsome.

In order to sow grass-walks, the ground must be first dug; and when it has been first dressed and laid even, it must be very carefully raked over, and all the clods and stones taken off, and then covered over an inch thick with good mould. This being done, the seed is to be sown pretty thick, that it may come up close and short; it must then be raked over again, to cover the seed, that if the weather should happen to be windy, it may not be blown away. It ought also to be observed, that where grass is sown in gardens, either for lawns or walks, there should always be a good quantity of the white trefoil, or Dutch clover, sown with it; for this will make a fine turf much sooner than any other sown grass,

grafs, and will continue a better verdure than any other of the grafs tribe.

In order to keep grafs-plats or walks handfome, and in good order, you may fow in autumn frefh feed over any places that are not well filled, or where the grafs is dead; but nothing improves grafs fo much, as mowing and conftant rolling.

When turf is laid in gardens, it is a general practice to cover the furface of the ground, under the turf, either with fand or very poor earth; the defign of this is, to keep the grafs fine, by preventing its growing too rank. This is proper enough for very rich ground, but it is not fo for land that is poor; for when this is praftised in fuch places, the grafs will foon wear out and decay in patches.

GRASSHOPPER, in zoology, a fpecies of the gryllus, frequent in patures. See GRYLLUS.

GRATINGS, in fhip-building, certain hatches or covers laid over the hatchways of a fhip, and croffed with battens of wood, fo as to let the light down between the decks of a fhip. See HATCHES.

GRATIOLA, hedge-hyffop, in botany, a genus of plants, whole flower is monopetalous and ringent; it hath five fubulated filaments, topped with roundifh antheræ. The fruit is an oval, acuminate capfule, compofed of two valves, and containing two cells, which are filled with a number of fmall feeds.

It is good in dropfies, jaundices, and other chronic complaints, taken in infufion; and though a rough and violent medicine, is reckoned a very powerful one.

GRAVE, in mufic, is applied to a found of a low or deep tone.

GRAVE *Accent*, in grammar, is a mark placed in this manner [*ˈ*] over fome vowel, and implies that the voice fhould be lowered in pronouncing that fyllable.

GRAVEL, in natural hiftory, is a congeries of fmall pebbles, which, being mixed with a fiff loam, makes lafting and elegant walks in our gardens.

Opinions, with regard to the choice of gravel, are various; fome are for having it as white as poffible, and in order to render it the more fo, caufe the walks to be often rolled with ftone rollers, which add a whitenefs to the furface. But this renders them very troublefome to the eyes, by reflecting too ftrofly the rays of light: fuch gravel, therefore, as will lie fmoother and reflect the leaft, fhould be preferred. Again, fome fcreen the gravel too fine, but this is an error; for if it be caft into a round heap, and the great ftones only are raked off, it will be the better. There are many kinds of gravel which do not bind, and by this means caufe a continual trouble of rolling, to little or no purpofe; as for fuch, if the gravel be loofe or fandey, you fhould take one load of ftrong loam and two of gravel, and fo caft them well together.

The beft and moft efteemed gravel is that of Black-heath, in Kent, which being mixed with a proper proportion of loam (found alfo on the fame common) makes the moft beautiful and lafting walks any where; nor is it confined to a few places about London, for we have known feveral tons of it exported to adorn the pope's garden at Rome, although it may be fuppofed fo much beneath its hofelinefs's dignity to tread upon it; but Italy cannot produce a more handfome terra firma.

The month of March is the propereft time for laying gravel; for it is not prudent to do it fooner, or to lay walks in any of the winter months before that time. In making thefe walks, great regard muft be had to the level of the ground, fo as to lay the walks with eafy defcents toward the low parts of the ground, that the wet may be eafily drained off: but when the ground is level, it will be proper to have fink-ftones laid by the fides of the walk, and at convenient diftances, to let off the wet; and when the ground is naturally dry, the drains from the fink-ftones may be contrived fo as to convey the water into felfpools, from which the water will foak away in a fhort time; but in wet lands there fhould be under-ground drains, to convey the water off, either into ponds, ditches, or the neareft place proper to receive it.

Some are apt to lay gravel-walks too round, but this is an error; becaufe they are not fo good to walk upon; and befides, it makes them look narrow; one inch is enough in a crown of five feet; and it will be fufficient, if a walk be ten feet wide, that it lies two inches higher in the middle than it does on each fide; if fifteen feet, three inches; if twenty feet, four inches; and fo in proportion.

For the depth of gravel-walks, fix or eight inches may do well enough; and a foot in thicknefs will be fufficient for any; but then there fhould always be a depth of rubbifh laid under the gravel, efpecially if the ground be wet.

Some turn up gravel-walks into ridges, in December, in order to kill the weeds; but this is very wrong, fince it never answers the end; and, therefore, if conftantly rolling them after rain and froft, will not effectually kill the weeds and mofs, you fhould turn the walks in March, and lay them down at the fame time.

In order to deftroy worms that fpoil the beauty of gravel or grafs walks, fome recommend the watering them with water made very bitter, by fteeping walnut-tree leaves in it; but if, in the firft laying of the walks, there be a good bed of lime-rubbifh laid at the bottom, it will prove the moft effectual method to keep out the worms, for they never harbour near lime.

GRAVEL-BIND. See the article CONVULVUS.

GRAVEL, in medicine, a very painful diftemper, arifing from a gritty matter concreting into fmall

small stones in the kidneys and bladder. See the article **STONE**.

GRAVELLING, an accident that often happens to a horse in travelling, occasioned by some small gravel stones getting between the hoof and the shoe, where they fester and fret the part.

It is cured by taking off the shoe, picking out all the gravel, washing the part affected, and then pouring upon it hot, a composition of sheep's tallow and bay salt melted together.

GRAVELLY Land, that which abounds with gravel and sand.

The best manure of these lands is marl, or any stiff clay that will dissolve with the frost, cow dung, chalk, mud, and half rotten straw from the dung-hill.

GRAVER, the name of a tool by which all the lines, scratches, and shades, are engraved on copper, &c.

There are three sorts of gravers, round-pointed, square-pointed, and lozenge-pointed. The round are best for scratching; the square-pointed for cutting the larger strokes; and the lozenge-pointed for the most delicate strokes: but a graver of a middle form, between the square and lozenge pointed, will make the strokes or hatches appear with more life and vigour. See **ENGRAVING**.

GRAVING, among sea-men, the act of cleaning a ship's bottom. See **CAREEN** and **DOCK**, where this operation is particularly explained.

GRAVITATION, in philosophy, the pressure which one body exerts upon another by reason of its gravity. See **ATTRACTION**.

GRAVITY, the natural tendency which all bodies have towards a center. See **ATTRACTION**.

GRAVITY, in mechanics, the tendency of bodies towards the center of the earth. Gravity is of two kinds, absolute and relative, or specific.

Absolute GRAVITY is the whole force with which a body tends downwards, or towards the center of the earth, and is always equal to the quantity of matter the body contains, without any regard to its bulk; so that the absolute gravity of a pound of wood is equal to that of a pound of iron.

Relative or Specific GRAVITY is the excess of gravity of one body above that of another of equal dimensions, and is always proportionable to the quantity of matter under that dimension. Thus a cubic inch of iron is heavier than a cubic inch of wood; for the iron being more dense than the wood, contains a greater quantity of matter under the same bulk.

For the method of finding the specific gravities of bodies, see *Hydrostatical BALANCE*.

GRAVITY of the Air. See **AIR** and **ATMOSPHERE**.

GRAY, or **GREY**, in horsemanship. See the article **GREY**.

GREASE, in farriery, a swelling and gourdiness of the legs of a horse.

This disease is generally the effects of a faulty blood, and happens mostly to horses of a gross constitution; sometimes it is owing to carelessness in the persons that look after them, for want of keeping their limbs clean and dry; but for the most part horses that run late in the winter at grass are the most subject to it; their blood by that means growing poor and dropical, exposes them first to swell in their limbs, and then to eruptions, which discharge a fetid stinking matter resembling melted glue, and when it turns sharp and corrosive, it becomes very troublesome. Sometimes the grease breaks out only behind, sometimes before; and when the constitution is very bad, it will break out in all the four limbs at the same time.

When the heels are very much swelled and full of hard scabs, it is necessary to begin the cure with poultices, which may be made with either turneps or rye-flower, turpentine, and hogs lard, mixed with spirit of wine or red wine-lees; and when the horse comes to move his limbs with less stiffness, it will be proper to purge him, which, in some cases, must be repeated five or six times before you can obtain the desired effect. Where there are pretty large swellings in the limbs, diuretics that work powerfully by urine, often succeed better than purges.

Molten GREASE, a distemper incident to very fat horses from over-riding, or any violent exercise.

It is known by the horse's voiding a greasy matter with his dung; though this symptom sometimes attends fat horses that stand much in the stable, and have but very little exercise, on their catching the least cold. But when a horse's grease is really melted, it is always accompanied with a fever, heat, restlessness, starting tremors or tremblings, great inward sickness, shortness of breath, and sometimes with the symptoms of a pleurisy.

In order to cure this disease, it is necessary to bleed plentifully in order to empty the vessels; and several rowels or issues should be cut in different parts of his body. Glysters are also of great service, and ought to be rather of the emollient kind, than purgative, as they are principally intended to cool the intestines; all the other internals ought likewise to be cleansing, attenuating, and opening.

GREAT, a term of comparison, applied to things of large or extraordinary dimensions, &c.

GREAT Circles of the Sphere, are such as divide the sphere into two equal parts or hemispheres, in contradistinction to the lesser circles, which cut the sphere into unequal parts. See **SPHERE**.

GREAT Circle Sailing. See the article **SAILING**.

GREEK, or **GRECIAN**, something relating to ancient Greece.

GREEK

GREEK Bible. See the article **BIBLE**.

GREEK Church, that part of the Christian church established in Greece and other parts of Turkey.

GREEK Language, the language spoken by the ancient Greeks, and still preserved in the writings of Plato, Aristotle, Demosthenes, Thucydides, Xenophon, Homer, Hesiod, &c.

The Greek language was that of a people who had a taste for the arts and sciences, which they happily cultivated; and hence it abounds with very significative terms, which are often borrowed by the moderns, and applied to any new discovery, instrument, machine, &c.

GREEK Orders, in architecture, are the Doric, Ionic, and Corinthian; the other two, namely, the Tuscan and Composite, being called the Latin orders.

GREEK Valerian, in botany. See **POLEMONIUM**.

GREEN, one of the original colours of the rays of light. See the article **COLOUR**.

GREEN, among painters and dyers, is a colour produced by a mixture of yellow and blue, which will be either deeper or lighter in proportion to the quantity of yellow used in the composition.

GREEN-CLOTH, a board or court of justice, held in the counting-house of the king's household, composed of the lord-steward, and the officers under him, who sit daily, and take cognizance of matters of justice within the verge of the court, which extends about two hundred yards every way from the last gate of the palace where his majesty resides.

GREEN-FINCH, in ornithology, the English name of the greenish fringilla, having its wings and tail variegated with yellow. It is a very common bird with us, and something larger than the chaffinch.

GREENHOUSE, a conservatory, or house erected in a garden, for the preservation of those sorts of plants which cannot endure the cold of our winters if exposed to the open air.

A greenhouse is distinguished from a stove to hot-house by its not having much artificial heat used in it; therefore those plants which are usually placed in it are not very tender, and will bear to be out in the open air during the summer season. In plate LX. fig. 1. is exhibited a view of a greenhouse with two glass cases adjoining to the ends; these may be used for the preservation of succulent plants, or for forcing roses, strawberries, &c. according to the fancy of the owner; and vines may be trained within-side from the bottom without, whereby in summer they will produce excellent bunches of the finest and most delicious grapes, of those sorts which would not ripen without doors with us, and would also be a good succession to those grapes which are forced in the stove. The length of these glass

cases may be from ten to twenty-five feet, and eight or nine feet in width, with flues, *f*, in the back, to be used in damp or frosty weather; the door-way, *a*, at those times may be opened, which will admit from the glass-cases so much warmth into the greenhouse as to keep out the frost, which is all the artificial heat required. The upper part of the fourth side of the roof of the greenhouse may be tiled or slated, under which shutters should be so contrived that by means of lines and pulleys they may be let down on the glasses or pulled up at pleasure, these will be a good security against frost, snow, or hail; the pillars in front should not be broader than may be thought necessary for the support of the roof, for there cannot be too much light in a greenhouse; the glasses in front should be sliding sashes, in order to give air to the plants at proper times; these should have shutters which may fold back against the piers within side, the middle one should be a glass door, for the convenience of bringing in or carrying out the plants; this need not be used at other times, as there are other entrances into the greenhouse, as out of the glass cases at *a*, or from the sheds at *b*; these sheds are very convenient for tools and other purposes, as likewise they keep the back of the cases warm; and it would not be amiss if one was continued behind the greenhouse, to prevent the frost and damps entering that way, otherwise the back requires a greater thickness of brick-work. In the section, the space marked *r*, between the roof and the ceiling *c*, should be filled up with straw, pease-haum, reeds, fern, or some such matter, to prevent the frost penetrating that way. The depth of the greenhouse should not be less than twelve feet, nor more than twenty, we think about fifteen or sixteen feet a good dimension for if it exceeds twenty, there must be more rows of plants placed to fill the house than can with convenience be reached in watering and cleaning; nor are houses of too great depth so proper for keeping of plants as those of a moderate size; as to the length, it should be proportioned to the quantity of plants it is to contain; about fifty feet is a moderate length, when the width is about fifteen, for if it is longer, the middle part of the house will receive no benefit of the fires in severe frosts. The height of the sashes in front of the greenhouse may be from eight to sixteen feet, and should be glazed with crown glass, but the slope parts of both places should be glazed with green glass, for if they are glazed with crown glass, the leaves of the plants are very apt to be burnt in different places, in hot sun-shine days in March or April, which frequently happens by the uneven panes collecting the rays of the sun to a focus, but the green glass is not so likely to do so: the ceiling and the walls should be stuccoed, or plastered and white-washed, but stucco is best, as it does not rub or peel off; this is necessary to help to keep out the frosts, as also to reflect

Greenhouse.

Fig. 1.

Fig. 3. Honey-comb.

Fig. 2. Hexagon.

Fig. 1. Section.

reflect the light, for there cannot be too much light, as was observed before. The floor of the greenhouse, &c. which should be laid either with Bremen squares, Purbeck stone, broad tiles, or hard bricks, according to the fancy of the owner, must be raised a foot at least above the surface of the ground whereon the house is placed; but if the situation is moist and springy, and thereby subject to damps, it should be raised at least three feet above the surface; and if the whole is arched with low brick arches under the floor, it will be of great service in preventing the damps rising in winter, which are often very hurtful to the plants, especially in great thaws, when the air is often too cold to be admitted into the house to take off the damps.

In this greenhouse the plants are to be disposed so as to form a rising surface from the front to the back; trussels of different heights are necessary to place the plants on when their heights are too equal, the lowest row should be forwardest next the windows, leaving a space to walk along; the rows of plants should rise gradually from the first, in such a manner that the heads of the second row should be entirely advanced above the first, the stems being only hid thereby, and so on for the rest. At the back of the house within-side there should be a passage left of four or five feet, for the conveniency of watering the plants, as also to admit of a current of air round them, that the damps occasioned by the perspiration of the plants may be better dissipated, which by being pent in too closely often occasions a mouldiness upon the tender shoots and leaves; and when the house is close shut up, this stagnating rancid vapour is often very destructive to the plants, for which reason they should never be crowded close together. In the principal house should be placed the most admired evergreens, such as orange, lemon, and citron trees, myrtles, geraniums, &c. the lemon and citron trees next the fire (see the plan) they being more tender than the orange; and where there are various sorts of plants they should be so disposed that their different foliage and tints of green may make an agreeable contrast; but as to the several sorts of succulent plants, such as aloes, sedums, torch-thistles, melon-thistles, euphorbiums, &c. (as was before observed) they should be placed in the glass-cases by themselves, as there is a great difference in nature between evergreens, herbaceous plants, and those we call succulent.

The sloping glasses of these cases should be made to slide, the upper-ones over the lower, which may be fixed, as also the front glasses may be contrived one to slide by the other, this is absolutely necessary to admit air to the plants in warm weather in a greater or lesser quantity according as there may be occasion.

But, besides the conservatories here mentioned, it will be proper to have a deep hot bed frame, such as is commonly used to raise large annuals in the

spring; into which may be set pots of such plants as come from Carolina, Virginia, &c. while the plants are too small to plant in the open air; as also may other sorts from Spain, &c. which require only to be screened from the violence of the frosts, and should have as much free air as possible in mild weather; which can be no better effected than in one of these frames, where the glasses may be taken off every day when the weather will permit, and put on every night; and in hard frosts, the glass may be covered with mats, straw, pease-haulm, or the like, so as to prevent the frost from entering the pots to freeze the roots of the plants, which is what will, many times, utterly destroy them; though a slight frost pinching the leaves or shoots very seldom does them much harm: if these are sunk a foot or more below the surface of the ground, they will be the better, provided the ground is dry; otherwise they must be wholly above ground: the sides of this frame should be built with brick, with a curb of wood laid round on the top of the wall, into which the gutters, on which the glasses slide, may be laid: the back wall of this frame may be about five feet high, and the front three feet, the width about six feet, and the length in proportion to the number of plants: as the plants which this frame is designed to protect during the winter are hardy enough to admit of being removed out of it in April, it may be used for raising in the summer a crop of melons, &c. which will keep it fully employed all the year.

GREGARIOUS, an epithet applied to such animals as live together in flocks or herds.

GREGORIAN Calendar. See the article **CALENDAR**.

GREGORIAN Year. See **YEAR**.

GREWIA, in botany, a genus of plants whose flower consists of a coriaceous coloured calyx, composed of five lanceolated leaves, the corolla is formed of five petals of the shape of the cup, but less, and emarginated at the base; the stamina are composed of a very great number of setaceous filaments, topped with roundish anthera. The fruit is a quadrangular berry having four cells, each inclosing a globe seed.

GREWT, among miners, implies earth of a different colour from the rest, found on the banks of rivers as they are searching for mines.

GREY, or **GRAY**, a mixed colour compounded of black and white. See **COLOUR**.

GRIFFON, in heraldry, an imaginary animal, supposed by the ancients to be half eagle and half lion.

GRINDING, *Trituratio*, the reducing hard substances to fine powders, by means of mills, rubbing them in a mortar, or with a muller on a marble.

GRIPE, in husbandry, a small ditch cut across a meadow or ploughed land, in order to drain it.

GRIPEs.

GRIPES, among sailors, certain ropes hooked to the decks of a ship, and drawn tight over the boats, to secure and prevent them from being shaken by the agitation of a ship at sea.

GRIPING, in the sea language, the inclination of a ship to run to the windward of her course, when the steers with a wind on either quarter.

This is partly occasioned by the shock of the waves which strike her on her weather-quarter, but chiefly by the arrangement of the sails, which dispose her at such a time to edge continually to windward. See the article **QUARTER**.

GRIST, in country affairs, implies corn already ground or ready for grinding.

GROAT, an English money of account, equal to four-pence.

GROGRAM, among manufacturers, a kind of stuff composed of silk and mohair.

GROIN, *Pubes*, in anatomy. See the article **PUBES**.

GROOM, a name applied to several superior officers belonging to the king's household.

GROOM is more particularly used for a servant appointed to attend horses in the stable.

GROMMET, among sailors, a sort of wreath or ring of rope to fasten a sail to any stay, upon which it is drawn along at the time of hoisting and lowering it, by the help of these grommets, as a curtain is extended or drawn together along its rod by the assistance of rings.

GROOVE, among miners, the shaft or pit sunk into the earth, whether in the vein or not.

GROOVE, among joiners, implies the channel made by their plough in the edge of a moulding, &c.

GROSS-WEIGHT, among merchants, signifies the whole weight of any commodity, including the dust, dross, and bag, chest, &c. in which it is contained.

GROSSULARIA, the gooseberry and currant-bushes. See **RIBES** and **GOOSEBERRY**.

GROTESQUE, something whimsical, extravagant, and monstrous.

GROTTO, in natural history, a large deep cavern in some rock or mountain.

GROTTO is also used for a small artificial edifice made in a garden, in imitation of a natural grotto.

The outides of these grottos are usually adorned with rustic architecture, and their inside with shell-work, coral, &c. and also furnished with various fountains, and other ornaments.

GROVE, in gardening, a small wood impervious to the rays of the sun.

Groves are the greatest ornaments to a garden; nor can a garden be complete which has not one or more of these. In small gardens there is scarce room to admit of groves of any extent: yet, in these, there should be at least one contrived, which should be as large as the ground will allow it: and, where

these are small, there is more skill required in the disposition, to give them the appearance of being larger than they really are.

Groves are of two sorts, viz. open and close; open groves are such as have large shady trees, which stand at such distances, as that their branches may approach so near to each other, as to prevent the rays of the sun from penetrating through them: but as such trees are a long time in growing to a proper size for affording a shade, so, where new groves are placed, the trees must be placed closer together, in order to have shade as soon as possible; but, in planting of these groves, it is much the best way to dispose all these trees irregularly, which will give them a greater magnificence, and also form a shade sooner, than when the trees are planted in lines; for, when the sun shines between the rows of trees, as it must do some part of the day in summer, the walks between them will be exposed to the heat, at such times, until the branches of these trees meet; whereas, in the irregular plantations, the trees intervene, and obstruct the direct rays of the sun.

When a person, who is to lay out a garden, is so happy as to meet with large full grown trees upon the spot, they should remain inviolate, if possible; for it will be better to put up with many inconveniences, than to destroy these, which will require an age to retrieve; so that nothing but that of offending the habitation, by being so near as to occasion great damps, should tempt the cutting them down.

Most of the groves which have been planted either in England, or those celebrated gardens in France, are only a few regular lines of trees; many of which join to the habitation, or lead to some building, or other object: but these do not appear so grand, as those which have been made in woods, where the trees have grown accidentally, and at irregular distances; where the trees have large spreading heads, and are left at such distance as to permit the grass to grow under them, then they afford the greatest pleasure; for nothing is more noble than fine spreading trees with large stems, growing through grass, especially if the grass is well kept, and has a good verdure; beside, most of these planted groves have generally a gravel walk, made in a straight line between them; which greatly offends the sight of persons who have a true taste: therefore, whenever a gravel walk is absolutely necessary to be carried through these groves, it will be much better to twist it about, according as the trees naturally stand, than to attempt regularity: but dry walks under large trees are not so useful as in open places; because the dropping of the trees will render these walks useless, after rain, for a considerable time.

Close groves have frequently large trees standing in them; but the ground is filled under these with shrubs, or under-wood; so that the walks which are made

made in them are private, and screened from the winds; whereby they are made agreeable for walking, at such times when the air is too violent or cold for walking in the more exposed part of the garden.

These are often contrived so as to bound the open groves, and frequently to hide the walls, or other inclosures, of the garden: and when they are properly laid out, with dry walks winding through them, and on the sides of these, sweet-smelling shrubs and flowers irregularly planted, they have a charming effect: for here a person may walk in private, sheltered from the inclemency of cold or violent winds, and enjoy the greatest sweets of the vegetable kingdom: therefore, where it can be admitted, if they are continued round the whole enclosure of the garden, there will be a much greater extent of walk: and these shrubs will appear the best boundary where there are not fine prospects to be gained.

These close groves are by the French termed *bosquets*, from the Italian word *boschetto*, which signifies a little wood: and in most of the French gardens there are many of them planted; but these are reduced to regular figures, as ovals, triangles, squares, and stars: but these have neither the beauty or use which those have that are made irregularly, and whose walks are not shut on each side by hedges, which prevents the eye from seeing the quarters; and these want the fragrancy of the shrubs and flowers, which are the great delight of these private walks; add to this, the keeping of the hedges in good order, is attended with a great expence; which is a capital thing to be considered in the making of gardens. *Miller's Gard. Dict.*

GROUND, in agriculture; see **EARTH** and **SOIL**.

GROUND, in painting, the surface upon which the figures and other objects are represented.

The ground is properly understood of such parts of the piece as have nothing painted on them, but retain the original colours upon which the other colours are applied to make the representations.

A building is said to serve as a ground to a figure, when the figure is painted on the building.

GROUND-ANGLING, a method of angling without a float, only with a plumb of lead, or rather a bullet, because it will roll on the ground.

GROUND-IVY, *hedera terrestris*, in botany; see **IVY**.

GROUND-PINE, in botany; see **CHAMEPITYS**.

GROUND-TAKLE, among sailors, all sorts of ropes which belong to the anchors, or for mooring a ship; as cables, hawfers, tow-lines, warps, buoy-ropes, &c.

GROUND-WORK, among builders; see **FOUNDATION**.

GROUNDING, in the sea language, a ship is

said to ground when she strikes and rests upon the ground.

GROUNDSEL, in botany; see **SENEGIO**.

GROUP, in painting and sculpture, an assemblage of two or more figures of men, beasts, fruits, &c. which have some apparent resemblance to one another.

GROUSE, or **GROWSE**, the name of a very valuable bird, of the size of a full-grown fowl. Its head is large, and adorned with a very beautiful scarlet protuberance over the eyes, which are remarkably piercing. It is a native of England, tho' not very common, and lives on large mountainous heaths.

GROWAN, among the Cornish miners, implies a coarse gritty stone of a greyish colour, which they are often obliged to dig through, before they reach the tin ore.

GRUB, the English name of the hexapode worms, or maggots, hatched from the eggs of beetles.

GRUBS, in medicine, certain unctuous pimples rising on different parts of the face, particularly in the alæ of the nose. They are cured by cooling physic, and such medicines as have a tendency to cleanse the blood.

GRUBBING, a term used by our farmers to signify the taking up the roots of trees.

GRUME, *Grumus*, in medicine, implies a concretion of blood, milk, or other similar substance.

GRUS, the crane, in ornithology, a bird of the heron kind. See **CRANE**.

GRYLLOTALPA, the mole cricket, in natural history, a creature approaching to the locust kind, and very properly called by this name by Mosket, as it has much of the form of the cricket, and makes a noise like it in the evening; and is, like the mole, continually employed in digging the ground.

GRYLLUS, in zoology, the name of the cricket and locust kind, which, together with the grasshopper, form one genus of insects.

GUAIACUM, or **QUAJACUM**, in botany, a genus of plants, the flower of which consists of a monophyllous cup, cut into five parts, the corolla is composed of five obato-oblong concave petals, which spread open. The fruit is a roundish, obliquely acuminate drupe, deeply furrowed, inclosing a hard nut.

The wood of guaiacum is extremely hard and solid, of a dense compact texture, and remarkably heavy, so as to sink in water; it is of a blackish yellow colour in the middle, and sometimes variegated. This wood comes over in large pieces, weighing four, five, or more, hundred weight, from Jamaica, Mexico, Porto-rico, St. Domingo, and other parts of the West-Indies; it is of a fragrant smell, and

and of an aromatic and pungent, but somewhat bitterish, taste.

When the tree is standing, or newly felled, the bark adheres so firmly as not to be got off even with iron tools; after lying for some time it separates easily. On account of its great hardness, solidity, and indisposition to crack, it is employed by the turners, and others, for several of the more curious mechanic uses. In Holland, at Hamburg, and other places of large commerce, it is rasped in work-houses established for that purpose, after the same manner as the colouring-woods; and from these the druggist and apothecary are supplied.

A strong decoction of guaiacum is used as an alterative diet-drink in venereal, cancerous, and other disorders, from an impurity of the blood and juices. Hoffman recommends the spirituous extract (which is the most active preparation) as a high antidote against the venereal poison, provided it be used properly, according to the laws of medicine. He mentions also another resinous preparation of this wood, under the title of "A singular resin, of a stimulating errhine quality, and possessing also a corroborating power, highly friendly to the nervous parts of the head." This, according to his account, is the resin that precipitates in boiling down a watery decoction of the wood.

Gum-GUAIACUM, so called, is a resin exuding from the guaiacum-tree. It is of a brown colour, partly reddish, and often greenish, brittle, of a glossy surface when broke, of a pungent taste; and when rubbed or heated, of a not disagreeable smell: its smoke, in burning, has somewhat the smell of that of wood. Such should be chosen as has pieces of the bark adhering, and easily parts from them by a few quick blows. The masses which have no bark, especially the large ones, are often sophisticated. I received for gum-guaiacum, a whole box of an artificial composition of colophony and balsam of sulphur: this abuse was readily distinguishable by the smell of the compound, when laid upon burning coals, and even by its appearance upon breaking.

Out of an ounce of gum-guaiacum, rectified spirit of wine dissolves six drams and two scruples: of the remainder, water applied at first, extracts four scruples out of an ounce: of the residuum, spirit dissolves four drams and two scruples. In distillation, it gives over a little both to water and to spirit, so little as to be altogether inconsiderable.

Its virtues are the same with those of the wood. It is used pretty frequently in England, very rarely in Germany, the pure resin artificially extracted from the wood by spirit of wine, advantageously and elegantly supplying its place.

GUAJAVA, or *GUAVA*, in botany, the name by which Tournefort calls the *psidium* of Linnaeus. See *PSIDIUM*.

GUANABANUS, the custard-apple, in botany, a genus of plants whose characters are as follow:

The empalement of the flower consists of three small pointed leaves; the flowers of some sorts have only three petals, but in others six; in the latter, three are alternately less than the others: from the empalement arises the pointal, which afterwards becomes an oval, or round, fleshy, soft fruit, inclosing several oblong, smooth, hard seeds.

GUARANTY, in policy, the engagement of neutral kindoms or states, whereby they undertake that certain treaties should be inviolably observed.

GUARD, in a general sense, signifies the defence or preservation of any thing; the act of observing what passes, in order to prevent surprize; or the care, precaution, and attention we make use of, to prevent any thing happening contrary to our intention and inclinations.

GUARD, in the military art, is a duty performed by a body of men, to secure an army or place from being surprized by an enemy.

In a garrison, the guards are relieved every day, and it comes to every soldier's turn once in three days; so that they have two nights in bed, and one upon guard.

To be upon guard, to mount the guard, to dismount the guard, to relieve the guard, to change the guard, the officer of the guard, or the serjeant of the guard, are words often used, and well understood.

Advanced-GUARD is a party of either horse or foot, that marches before a more considerable body, to give notice of any approaching danger.

When an army is upon the march, the grand-guards, which should mount that day, serve as an advanced-guard to the army: in small parties, six or eight horse are sufficient, and these are not to go above four or five hundred yards before the party.

An advanced-guard is also a small body of twelve or sixteen horse, under a corporal, or quarter-master, posted before the grand-guard of a camp.

Artillery-GUARD is a detachment from the army to secure the artillery; their corps-de-garde is in the front, and the centres round the part. This is a forty-eight hours guard: and upon a march, they go in the front and rear of the artillery, and must be sure to leave nothing behind; if a gun or wagon break down, the captain is to leave a part of his guard to assist the gunners and matrosses in getting it up again.

Corps-de-GARDE, are soldiers entrusted with the guard of a post, under the command of one or more officers.

Counter-GUARD, in fortification. See the article *COUNTER-GUARD*.

Forrage-GUARD, a detachment sent out to secure the forragers, which are posted at all places, where either the enemy's party may come to disturb the forragers;

forragers; or where they may be spread too near the enemy, so as to be in danger of being taken. They consist both of horse and foot, and must stay at their posts till the forragers all come off the ground.

Grand-GUARD, three or four squadrons of horse, commanded by a field-officer, posted at about a mile and a half from the camp, on the right and left wings, towards the enemy, for the security of the camp.

Main-GUARD, that from whence all the other guards are detached.

Piquet-GUARD, a good number of horse and foot always in readiness in case of an alarm: the horse are all the time saddled, and the riders booted. The foot draw up at the head of the battalion, at the beating of the tattoo; but afterwards return to their tents, where they hold themselves in readiness to march, upon any sudden alarm. This guard is to make resistance, in case of an attack, till the army can get ready.

Quarter-GUARD, a small guard, commanded by a subaltern officer, posted by each battalion, about an hundred yards before the front of the regiment.

Rear-GUARD, that part of the army which brings up the rear, which is generally the old grand-guards of the camp. The rear-guard of a party is six or eight horse, that march about four or five hundred paces behind the party. The advanced-guard of a party on its going out, make the rear-guard on its return.

Standard-GUARD, a small guard, under a corporal, out of each regiment of horse, and placed on foot, in the front of each regiment.

Van-GUARD, that part of the army which marches in the front.

GUARDS also imply the troops kept to guard the king's person.

Yeomen of the GUARDS. See **YEOMEN**.

GUARD, in fencing, implies a posture proper to defend the body from the sword of the antagonist.

GUARD-BOAT, in naval affairs, a boat commanded by a lieutenant, appointed to row around the ships in a harbour to see that the officers in each ship observe their watch, and call to the boat as the passes, and do not suffer them to board without a watch-word.

GUARD-SHIP, a vessel of war appointed to superintend the marine affairs in a harbour or river, and see that the ships who are not commissioned have their proper watch kept duly every night, also to receive and secure seamen who are impressed in the time of war.

GUARDIAN, in law, a person who has the charge or custody of such person or persons as have not sufficient discretion to take care of themselves; as idiots, or children under age.

GAUZUMA, bastard cedar-tree, in botany, a genus of trees whose characters are as follow:

It hath a regular flower consisting of five leaves, which are hollowed like a spoon at their base; but at their tops are divided into two parts, like a fork; the flower cup consists of three leaves, from whence arises the pointal, which afterwards becomes a roundish warted-fruit, which has five cells inclosing many seeds.

GUIDON, the name of a sort of standard carried by the king's life-guards; so called from its being broad at one extreme, and almost pointed at the other, and slit, or divided into two.

GUIDON also implies the officer who carries the guidon.

GUILANDINA, in botany, a genus of plants whose flower consists of a campanulated cup, with five concave lanceolated petals. The stamina are ten subulated filaments, topped with obtuse incumbent antheræ.

The fruit is a ventricose, compressed rhomboidal pod, having one cell, including oleose seeds of a globose compressed form.

GUILD, or **GILD**, a Saxon word signifying a company, or fraternity.

GUILDHALL, the chief hall of a city or corporation where the courts are held.

GUINEA-PEPPER, in botany. See the article **CAPSICUM**.

GUINEA-PIG, in zoology, a quadruped of the rat kind, with a variegated body, resembling in some measure that of a young pig, whence the name.

GUITER, a musical instrument of the stringed kind, used greatly in Spain, and at present in England.

GULA, in anatomy, the same with œsophagus. See **ŒSOPHAGUS**.

GULA, or **GOLA**, in architecture, the same with cymatium, or ogce. See **CYMATIUM** and **OGEE**.

GULES, in heraldry, the true scarlet colour, and expressed in engraving by lines falling perpendicular from the top of the escutcheon to the bottom.

GULPH, in geography, a part of the sea almost surrounded by the land.

GUM, in pharmacy, a concreted vegetable juice, which transudes through the bark of certain trees, and hardens upon the surface.

GUM, among gardeners, a kind of gangrene incident to fruit-trees of the stone kind, arising from a corruption of the sap, which, by its viscidness, not being able to make its way through the fibres of the tree, is, by the protrusion of other juice, made to extravasate and ouze out upon the bark.

When the distemper furrounds the branch, it admits of no remedy, but when only on one part of a bough, it should be taken off to the quick, and some cow-dung clapped on the wound, covered over with a linen-cloth, and tied down. **M. Quin-**

tinie

tinie directs to cut off the morbid branch two or three inches below the part affected.

GUMS, *Gingivæ*, in anatomy; see **GINGIVÆ**.

GUM-BOILS, a morbid affection of the gums called by writers of surgery parulides. These are of different degrees, and usually arise from pains in the teeth. They are to be treated by discutients as other inflammatory tumors, but if these fail, or the disorder is neglected, it usually terminates in an abscess or fistula. Sage, camomile, and elder flowers, boiled in milk and water, make a good gargarism to be held in the mouth, and the remaining herbs may be sewed up in a bag to be kept hot to the cheek. A half roasted fig is a very good internal application, and, when the softness of the tumor shews that the matter is suppurated, it ought immediately to be opened with the lancet, to prevent the matter's lodging there, and eroding the bone, and producing a fistula or caries.

GUN, a fire-arm, or weapon of offence, which forcibly discharges a ball, shot, or other offensive matter, through a cylindrical barrel, by means of gun-powder. See the article **GUN-POWER**.

Gun is a general name, under which are included divers or even most species of fire-arms. They may be divided into great and small.

Great guns, called also by the general name cannons, make what we also call ordnance, or artillery; under which come the several sorts of cannons, as cannon-royal, demi-cannon, &c. Culverins, demi-culvers, fakers, minions, falcons, &c. See **CANNON**, **CULVERIN**, &c. as also **ORDNANCE** and **ARTILLERY**.

Small guns include musquets, musquetoons, carabines, blunderbusses, fowling-pieces, &c. See the article **MUSQUET**, &c.

Pistols and mortars are almost the only sort of regular weapons, charged with gun-powder, that are excepted from the denomination of guns. See the articles **PISTOL** and **MORTAR**.

GUN is also a name given by the miners to an instrument used in cleaving rocks with gun-powder. It is an iron cylinder of an inch and a quarter thick, and about six inches long, and having a flat side to receive the side of a wedge, and a hole drilled thro' it to communicate with the inside of the hole in the rock. The hole is made of about eight inches deep, and in the bottom of it are put about two or three ounces of gun-powder; then this gun is driven forcibly in, so as to fill up the hole, and the wedge is driven in on its flat side to secure it. The priming at the hole is then fired by a train, and, the orifice being so well stopped by this gun, the force of the powder is determined to the circumjacent parts of the rock which it splits.

GUNNEL, in ship-building, the upper-part of a ship's side.

GUNNER, an officer appointed for the service

of the artillery; or a person skilled in the art of gunnery.

GUNNER of a Ship of War, an officer appointed to take charge of the artillery and ammunition abroad; and to teach the men the exercise of great guns.

GUNNERY, the art of determining the motion of bodies shot from mortars, cannon, &c. See the article **PROJECTILE**.

GUN-POWDER, a composition of salt-petre, sulphur, and charcoal, well mixed together and granulated; which easily takes fire, and expands with amazing force.

The invention of this composition is ascribed by Polydore Virgil to a chemist, who having accidentally put the ingredients above-mentioned into a mortar, and covered it over with a stone, it happened to take fire, and threw off the stone. Thelvel says that this chemist was one Constantine Anelzen, a monk of Friburg; but Belleforet and others assert it to be Bertholdus Schwartz: at least it is affirmed that he first taught the use of gun-powder to the Venetians, in the year 1380. Peter Mexia however contradicts this account, by shewing it to have been used by Alphonso XI. king of Castile, in the year 1342. Ducange adds, that there is mention made of this powder in the registers of the chambers of accounts of France, so early as the year 1338; and our countryman, Friar Bacon, expressly mentions the composition, in his treatise *De nullitate Magiæ*, published at Oxford in the year 1216.

Method of making GUN-POWDER. The following receipt for making gun-powder is taken from Dr. Shaw's Chemical Lectures.

Take four ounces of refined salt-petre, an ounce of brimstone, and six drams of charcoal; reduce these to a fine powder, and continue beating them for some time in a stone-mortar, with a wooden-pebble, wetting the mixture between whiles with water, so as to form the whole into an uniform paste, which is reduced to grains, by passing it through a white sieve for the purpose; and in this form, being carefully dried, it becomes the common gun-powder.

For greater quantities, mills are usually provided, by means of which more work may be performed in one day than a man can do in a hundred. See **MILL**.

The nitre or salt-petre is refined thus: dissolve four pounds of rough nitre as it comes to us from the Indies, by boiling it in as much water as will commodiously suffice for that purpose; then let it shoot for two or three days in a covered vessel of earth, which sticks laid across for the crystals to adhere to. These crystals being taken out, are drained and dried in the open air.

In order to reduce this salt to powder, they dissolve a large quantity of it in as small a proportion

of water as possible; then keep it constantly stirring over the fire, till the water exhales, and a white dry powder is left behind. See NITRE.

In order to purify the brimstone employed, they dissolve it with a very gentle heat; then scum and pass it through a double strainer. If the brimstone should happen to take fire in the melting, they have an iron cover that fits on close to the melting vessel, and damps the flame. The brimstone is judged to be sufficiently refined if it melts without yielding any foetid odour between two hot iron-plates into a kind of red substance.

The coal for the making of gun-powder is either that of willow, or hazel, well charred in the usual manner, and reduced to powder: and thus the ingredients are prepared for making this commodity; but as these ingredients require to be intimately mixed, and as there would be danger of their firing if beat in a dry form, the method is to keep them continually moist, either with water, urine, or a solution of sal-ammoniac: they continue thus stamping them together for twenty-four hours, after which the mass is fit for corning and drying in the sun, or otherwise, so as sedulously to prevent its firing.

Different kinds of GUN-POWDER. The three ingredients of gun-powder are mixed in various proportions, according as the powder is intended for musquets, great guns, or mortars; though these proportions seem not to be perfectly adjusted, or settled by competent experience.

Semienowitz for mortars, directs 100 lb of salt-petre, 25 lb of sulphur, and as many of charcoal; for great guns, 100 lb of salt-petre, 15 lb of sulphur, and 18 lb of charcoal; for musquets and pistols 100 lb of salt-petre, 8 lb of sulphur, and 10 lb of charcoal. Miethius extols the proportion of 1 lb of salt-petre to three ounces of charcoal, and two or two and a quarter of sulphur; than which, he affirms, no gun-powder can possibly be stronger. He adds, that the usual practice of making the gun-powder weaker for mortars than guns, is without any foundation, and renders the expence needlessly much greater: for whereas to load a large mortar, 24 lb of common powder is required, and consequently to load it ten times 240 lb, he shews by calculation, that the same effect would be had by 150 lb of the strong powder.

To increase the strength of powder, Dr. Shaw thinks it proper to make the grains considerably large, and to have it well sifted from the small dust. We see that gun-powder, reduced to dust, has little explosive force; but when the grains are large, the flame of one grain has a ready passage to another, so that the whole parcel may thus take fire nearly at the same time, otherwise much force may be lost, or many of the grains go away as shot unfired.

Method of trying and examining GUN-POWDER. There are two general methods of examining gun-

powder; one with regard to purity, the other with regard to its strength. Its purity is known by laying two or three little heaps near each other upon white paper, and firing one of them; for if this takes fire readily, and the smoke rises upright, without leaving any dross, or sculent matter behind, and without burning the paper, or firing the other heaps; it is esteemed a sign that the sulphur and nitre were well purified, that the coal was good, and that the three ingredients were thoroughly incorporated together; but if the other heaps also take fire at the same time, it is presumed that either common salt was mixed with the nitre, or that the coal was not well ground, or the whole mass not well beat, and mixed together; and if either the nitre or sulphur be not well purified, the paper will be black or spotted.

In order to try the strength of gun-powder, there are two kinds of instruments in use; but neither of them appear more exact than the common method of trying to what distance a certain weight of powder will throw a ball from a musket.

There has been much talk of a white powder, which, if it answered the character given it, might be a dangerous composition: for they pretend that this white powder will throw a ball as far as the black, yet without making a report; but none of the white powder we have seen, says Dr. Shaw, answers to this character; being, as we apprehend, commonly made either with touchwood or camphor, instead of coal.

Observations on the Force of GUN-POWDER. Gun-powder fired either in vacuum, or in air, produces by its explosion a permanent elastic fluid: for if a red-hot iron be included in a receiver, after being exhausted, and gun-powder be let fall on the iron, the powder will take fire, and the mercurial gage will suddenly descend upon the explosion; and though it immediately ascends again, yet it will never rise to the height it first stood at, but will continue depressed by a space proportioned to the quantity of gun-powder which was let fall on the iron.

The same production likewise takes place, when gun-powder is fired in the air: for if a small quantity of powder be placed in the upper-part of a glass tube, and the lower part of the tube be immersed in water, and the water be made to rise so near the top, that only a small portion of air is left in that part where the gun-powder is placed: if in this situation the communication of the upper-part of the tube with the external air be closed, and the powder be fired, which will easily be done by a burning glass, the water will in this experiment descend upon the explosion, as the quicksilver did in the last; and will always continue depressed below the place at which it stood before the explosion; and the quantity of this depression will be greater, if the quantity

quantity of powder be increased, or the diameter of the tube be diminished. From whence it is proved, that as well in air as in a vacuum, the explosion of fired powder produces a permanent elastic fluid. It also appears from experiment, that the elasticity or pressure of the fluid produced by the firing of gun-powder, is, *ceteris paribus*, directly as its density. This follows from hence, that if in the same receiver a double quantity of powder be let fall, the mercury will subside twice as much as in the firing of a single quantity.

To determine the elasticity and quantity of this elastic fluid, produced from the explosion of a given quantity of gun-powder, Mr. Robins premises, that the elasticity of this fluid increases by heat, and diminishes by cold in the same manner as that of the air; and that the density of this fluid, and consequently its weight, is the same with the weight of an equal bulk of air having the same elasticity, and the same temperature. From these principles, and from his experiments (for a detail of which, we must refer the reader to his *New Principles of Gunnery*, in Scholium to Prop. II.) he concludes, that the fluid produced by the firing of gun-powder will be $\frac{3}{4}$ of the weight of the gun-powder, and the ratio of the respective bulks of the powder, and the fluid produced from it, will be in round numbers 1 to 244.

Hence we are certain, that any quantity of powder, fired in any confined space, which it adequately fills, exerts, at the instant of its explosion, against the sides of the vessel containing it, and the bodies it impels before it, a force, at least 244 times greater than the elasticity of common air; or, which is the same thing, than the pressure of the atmosphere; and this without considering the great addition which this force will receive from the violent degree of heat with which it is endued at that time, the quantity of which augmentation is the next head of Mr. Robins's enquiry. He determines that the elasticity of the air is augmented when heated to the extremest heat of red hot iron, in the proportion of 796 to 194 $\frac{1}{2}$; and supposing that the flame of fired gun-powder is not less hot than red hot iron, and the elasticity of the air, and consequently of the fluid, generated by the explosion, being augmented by the extremity of this heat in the ratio of 796 to 194 $\frac{1}{2}$, it follows, that if 244 be augmented in the ratio, the resulting number, which is 999 $\frac{1}{2}$, will determine how many times the elasticity of the flame of fired powder, exceeds the elasticity of common air, supposing it to be confined in the same space which the powder filled before it was fired.

Hence, then, the absolute quantity of the pressure exerted by gun-powder, at the moment of its explosion, may be assigned: for, since the fluid then generated has an elasticity of 999 $\frac{1}{2}$, or, in round numbers, 1000 times greater than common air;

and since common air, by its elasticity, exerts pressure on any given surface, equal to the weight of the incumbent atmosphere, with which it is in equilibrio, the pressure exerted by fired powder, before it has dilated itself, is 1000 times greater than the pressure of the atmosphere; and consequently the quantity of this force on a surface of an inch square, amounts to above six ton weight, which force, however, diminishes as the fluid dilates itself. The variations of the density of the atmosphere does not any way alter the action of powder by any experiment that can be made. But the moisture of the air has a very great influence on the force of it; for that quantity which, in a dry season, would communicate to a bullet a velocity of 1700 feet in one second, will not, in damp weather, communicate a velocity of more than 12 or 1300 feet in a second, or even less, if the powder be bad and negligently kept.

The velocity of expansion of the flame of gun-powder when fired in a piece of artillery, without either bullet, or any other body before it, is prodigious. By the experiments of Mr. Robins, it seems this velocity cannot be much less than 7000 feet in a second. This, however, must be understood of the most active part of the flame: for, as was before observed, as the elastic fluid in which the activity of gun-powder consists, is only $\frac{3}{4}$ of the substance of the powder, the remaining $\frac{1}{4}$ will in the explosion be mixed with the elastic part, and will by its weight retard the activity of the explosion; and yet they will be so completely united as to move with uncommon motion; but the unelastic part will be less accelerated than the rest, and some of it will not even be carried out of the barrel, as appears by the considerable quantity of unctuous matter which adheres to the inside of all fire-arms, after they have been used. These inequalities in the expansive motion of the flame render it impracticable to determine its velocity, otherwise than from experiments.

To recover damaged GUN-POWDER. The method of the powder-merchants is this; they put part of the powder on a sail-cloth, to which they add an equal weight of what is really good, and with a shovel mingle it well together, dry it in the sun, and barrel it up, keeping it in a dry and proper place. Others again, if it be very bad, restore it by moistening it with vinegar, water, urine, or brandy: then they beat it fine, searce it, and to every pound of powder add an ounce, an ounce and a half, or two ounces, according as it is decayed, or melted salt-petre. Afterwards, these ingredients are to be moistened and mixed well, so that nothing can be discerned in the composition, which may be known by cutting the mafs; and then they granulate it as aforesaid. In case the powder be in a manner quite spoiled, the only way is to extract the

the salt-petre with water, according to the usual manner, by boiling, filtrating, evaporating, and crystallizing; and then with fresh sulphur and charcoal to make it up a-new again. In regard to the medical virtues of gun-powder, Boerhaave informs us, that the flame of it affords a very healthy fume in the height of the plague, because the explosive acid vapour of nitre and sulphur corrects the air; and that the same vapour, if received in a small close pent-up place, kills insects.

GUN-SHOT-WOUNDS, those made by shot, bullets, &c. shot from some species of fire-arms.

GUNTER'S-LINE, called also the *Line of Numbers*, and the *Line of Lines*, is a graduated line usually placed upon scales, sectors, &c. so called from Edmund Gunter, its inventor.

This line is no other than a logarithmic scale of proportionals, wherein the distance between each division is equal to the number of mean proportionals contained between the two terms, in such parts as the distance between 1 and 10 is 10000, &c. Wherefore,

If the distance betwixt 1 and 10 upon the scale be made equal to 10000, &c. equal parts, and .954 &c. the logarithm of 9 of the same parts, be set off from 1 to 9, it will give the division standing against the number 9. In like manner, if .903, .845, .778, which are the logarithms of 8, 7, and 6, of the same equal parts, be set off from 1 to 8, 7, and 6, they will give the divisions answering to the numbers 8, 7, and 6, upon the line. And after the same manner may the whole line be divided.

This line has been contrived various ways, for the advantage of having it as long as possible. It was first placed, by its inventor Edmund Gunter, on a two feet scale. After this, Wingate doubled the line, in order to render it susceptible of working right on or a-cross. Then, the learned Oughtred projected it in a circle, and also made it to slide: and, lastly, it was projected in a kind of spiral, by Brown.

But the method of using or applying it in all is not very different. In Gunter's and Wingate's projection, common compasses are used; in Oughtred's and Brown's, flat compasses, or an opening index; and in the sliding rule no compasses at all, the slider supplying the place of the compasses.

Description of GUNTER'S Line. This line is usually divided into an hundred parts, every tenth whereof is numbered, beginning with 1, and ending with 10. So that, if the first-great division 1 represent one tenth of any integer or whole number, the next 2 will represent 2 tenths; 3, three tenths, &c. and the intermediate divisions to many 100th parts of the same integer. Or, if these subdivisions represent 10 integers, then each of the larger divisions will represent 100, and the whole line will be 1000. In like manner, it may be ex-

tended to 10000 by making each subdivision 100. Hence, it is easy to conceive, that any number whatsoever may be found upon the rule, by increasing or decreasing the large divisions, and, consequently, this single line will represent the whole table of logarithms.

Use of GUNTER'S Line.—1. One number being given to be multiplied by another, to find their product.

Suppose the numbers given were 8 and 4, to find their product. Extend the compasses from 1 to 4, and that extent laid from 8, the same way, will reach to 32, the product required. Or, if you work by the sliding-rule, set 1, at the beginning of the sliding-piece, against 4 on the upper or fixed piece; and against 4 on the slider stands 32, on the upper or fixed piece; which is the product required. Whence it is abundantly evident, that the sliding-piece performs the office of the compasses, and therefore, when the method of solving any problem by the compasses is understood, there will be no difficulty of solving the same by the sliding-rule.

2. One number being given to be divided by another, to find the quotient.—Suppose it were required to divide 64 by 4. Extend the compasses from 4 to 1, and the same extent, laid the same way, will reach from 64 to 16, the quotient required.

3. Three numbers being given to find a fourth in direct proportion.—Let the numbers given be 7, 22, and 14. Extend the compasses from 7 to 22, which extent, laid the same way, will reach from 14 to 44, the fourth proportional required.

4. To find a mean proportional between 2 given numbers.—Bisect the distance between the two given numbers, and the point of bisection will fall on the proportional sought. Thus, if the numbers given be 32 and 8, the middle point between them will be 16, which is the mean proportional required.

5. To extract the square root of any number.—Bisect the distance between 1 on the line, and the point representing the given number; the half whereof being laid from one will give the root required. Thus the square root of 9 will be found to be 3, of 81, 9; &c. The reason of these operations will be easily conceived, by considering the nature of logarithms; for, as we have already observed, this line is no other than a projection of the table of logarithms, and, consequently, whatever is said of the latter may justly be applied to the former. See LOGARITHMS.

GUNTER'S QUADRANT, one made of wood, brass, &c. containing a kind of stereographic projection of the sphere on the plane of the equinoctial, the eye being supposed placed in one of the poles.

Besides the use of this quadrant in finding heights and distances, it serves also to find the hour of the day, the sun's azimuth, and other problems of the globe. See the article *Gunter's Quadrant*.

GUNTER'S SCALE, called by navigators simply the Gunter, is a large scale, generally two feet long, and about an inch and a half broad, with artificial lines delineated on it, of great use in solving questions in trigonometry, navigation, &c.

The line of numbers on these scales consists of two equal lengths, commonly called two radii; the first containing the logarithms of numbers from 10 to 100; and in the second are inserted those between 100 and 1000, or such of them as can conveniently be introduced.

These divisions are taken from a scale of equal parts; such, that 100 make the length of one radius; and from this scale the divisions for the sines, tangents, and versed sines, are also taken. Now, from this construction of the line of numbers, it is plain, that, as the numbers in one radius exceed those in the other, by one place in the scale of numeration, therefore the differences of their indices must also be unity: so that such numbers only, whose index differs by 1, can be estimated in a length of two radii; but in a length of three radii, numbers, whose indices differ by 2, may be read; and a difference of 3 may be reckoned in a length of 4 radii, &c. The tables of logarithmic sines, tangents, secants, and versed sines, are generally computed for a circle, whose radius is 10,000,000: therefore,

In the sines, the index 9 belongs to all } 90 0 0 and 5 44 36
between
The index 8 5 44 36 and 0 34 23
The index 7 to all bet. 0 34 23 and 0 3 27
6 0 3 27 and 0 0 21 &c.

In the tangents, the index 9 belongs to all } 45 0 0 and 5 42 10
between

And the indices, 8, 7, 6, &c. fall as in the sines.

In the versed sines, the index 9 belongs to all between } 180 0 0 and 90 0
0 belongs to all between 90 0 0 and 25 51
8 25 51 and 8 7
7 8 7 and 2 34
6 2 34 and 0 45 &c.

Now, as the length of the Gunter's scale admits of no more than two radii, or of such numbers only, whose index differs by unity; therefore, within this length, no more of the sines, tangents, or versed sines, can be introduced, than those whose index differs by unity: and as not only the greatest number among the sines and tangents, but also those more generally wanted, have the indices 9 and 8 differing by unity; therefore all the sines from 90°

to 0° 34', and all the tangents from 45° to 0° 34', are those only, which are put on these scales; the divisions answering to the lesser sines and tangents being omitted for want of room. And this is the reason why the sine of 90°, and the tangent of 45°, are limited by the same termination as the second radius on the line of numbers.

To construct the Line of logarithmic Sines on GUNTER'S Scale.—From the scale of equal parts, take the numbers expressing the arithmetical complements of the log-sines of the successive degrees, and parts of degrees intended to be put on the scale, descending orderly from 90°; then these distances, successively laid from the mark representing 90° at the right-hand end of the scale, will give the several divisions of a scale of logarithmic sines.

For the ends of any scale being assigned, the progressive divisions of that scale are laid thereon from that end which represents the beginning of the progression; or the same divisions may be laid from the other end, by taking the complements of the terms to the whole length of the scale.

Consequently the arithmetical complements of the sines are to be laid from the division representing 90 degrees.

To construct the Line of logarithmic Tangents on GUNTER'S Scale.—These are laid down in the same manner, and for the same reasons, that the sines were; the tangent of 45° standing against the sine of 90°.

The divisions for the tangents above 45° are reckoned on the same line from 45° towards the left-hand; or any tangent and its co-tangent are expressed by the same division.

Thus one mark serves for 40° and 50°, and the division at 30° serves also for 60°; that at 20° serves for 70°, &c. and the like is to be understood for the intermediate divisions.

For as the tangent of an arc is to a radius;

So is radius to the co-tangent of that arc.

Therefore the tangent is equal to the square of radius divided by the co-tangent.

And the co-tangent is equal to the square of radius divided by the tangent.

Now, the radius being unity, its square is also unity.

Therefore the tangent and co-tangent of any arc are the reciprocals one of the other.

But the reciprocals of numbers are correlatives to the arithmetical complements of their logarithms.

Therefore the logarithms of a tangent and its co-tangent are arithmetical complements one of the other, and consequently will fall at equal distances from 45 degrees.

Therefore, in the line of logarithmic tangents, the divisions to degrees under 45 serve also for those above, both being equally distant from 45 degrees.

To construct the Line of logarithmic versed Sines on GUNTER's Scale.—As the greatest number of degrees will fall within the limits of the scale by beginning at 18°, therefore the termination of this line is at 18°, which is put against 90° on the lines: and although the numbers annexed to the divisions increase in the order from right to left, yet they are only the supplements of the versed sines themselves.

Now subtract the logarithmic versed sines of such degrees and parts of degrees as are intended to be put on the scale, from the logarithm versed sine of 180°; then the remainder taken from the aforesaid scale of equal parts, and laid successively from the termination of this line, will give the several divisions sought.

The following Table to every 10 degrees was constructed in the foregoing manner, and are the numbers to be taken from the scale of equal parts, for the degrees they stand against.

Deg.	Supplements of Versed Sines.	Deg.	Supplements of Versed Sines.	Deg.	Supplements of Versed Sines.
180	0,00000	120	0,12494	60	0,60206
170	0,00331	110	0,17327	50	0,74810
160	0,01330	100	0,23149	40	0,93190
150	0,03011	90	0,30103	30	1,17401
140	0,05402	80	0,38387	20	1,52066
130	0,08545	70	0,48282	10	2,21941

From this table it appears, that the least versed sine which can be introduced within the length of a double radius, falls between 10° and 20°, where the index changes from 1 to 2; which will happen about 11° 28'.

If a table of logarithm versed sines to 180° are wanting, they are easily made by the following rule:

“Take the logarithm sine of 30 degrees from twice the logarithm sine of (N) any number of degrees, the remainder is the logarithm versed sine of (2N, or) twice those degrees.”

For it is a well known geometrical property, that the sine of any arc (A) is a mean proportional between radius (R) and half the versed sine of twice that arc.

Therefore, putting v for the versed sine, and s for the sine;

$$\text{The } v 2 A = \left(\frac{2 s s A}{R} = s s A \times \frac{2}{R} = s s A \times \frac{2}{10} \right) s s A \times \frac{2}{5}; \text{ radius being } 10.$$

Or the log. $v 2 A = 2 \log. s A - \log. 5$.

But, when radius is 10, the sine of 30° is 5.

Therefore the log. $v 2 A = 2 \log. s A - \log. \text{ sine of } 30^\circ$.

Most of the writers on this subject give the fol-

lowing rule for laying down the divisions of this line:

“From the line of logarithmic sines, take the distance between 90° and any arc; that distance being twice repeated, from the termination of the line of versed sines, will give the division for twice the complement of that arc.”

Thus the distance between 90° and 20° on the sines twice repeated, gives the versed sine of 140°; or twice 70°, the complement of 20°. For the divisions to be laid on this line, are the differences between the logarithm versed sine of 180°, and the logarithm versed sines of the successive arcs.

Now the difference between the logarithm versed sines of 180°, and of any arc 2 A, is log. ver. sine 180 — 2 log. sin. A + log. sin. of 30°.

Or, 10,30103 + 9,69897 — twice the log. sin. of A.

Or, 20,00000 — twice logarithm sine of A.

Or the arithmetical complement of twice log. sine of A.

That is, the difference between the logarithm versed sine of 180°, and the logarithm versed sine of any arc, is equal to double the arithmetical complement of the logarithm sine of half that arc, rejecting the indices.

But as the differences give the divisions to the supplements of the real versed sines, therefore the arithmetical complement of the logarithm sine of any arc, being doubled, will give the distance of the division for the supplement of twice that arc on the line of versed sines.

Thus, for 70°, the logarithm sine is 9,97299.

The arithmetical complement is 0,02701.

Its double is 0,05402.

Which is the number in the foregoing table standing against 140°, and is the supplement versed sine of twice 70°.

Now, as the arithmetical complement of the log. sines of arcs are the distances on the line of sines between 90°, and the divisions to those arcs; therefore the distances between 90 degrees and any arc, being twice repeated, will give the division of the supplemental versed sine to twice the co-sine of that arc: *Phil. Trans.* Vol. XLIX.

GURNARD, in ichthyology, the English name of two species of trigla.

These fishes, from their different colours, are called the grey and red gurnard. The grey gurnard has a bifid and spinose snout, with two spines at each eye. The red kind has likewise the rostrum bifid, and the covering of the gills striated, and each of them armed with three spines. This last is a very remarkable spinose fish, which seldom exceeds a foot in length.

Both these fishes make a singular noise, when out of the water, not unlike the grunting of a hog: whence their English name.

GUSSET, in heraldry, is formed by a line-drawn

drawn from the dexter or sinister chief points, and falling down perpendicularly to the extreme base.

GUTTÆ, in architecture, are ornaments in form of little cones, in the platform of the Doric cornice, or architrave, underneath the triglyphs, representing a sort of drops or bells, usually fix in number. They are sometimes called lachrymæ, campanæ, or campanulæ.

GUTTÆ Rosacea, in medicine, denotes a red or pimpled face; a distemper which, though not always owing its original to hard drinking, is nevertheless most incident to tipplers of strong beer, wines, spirits, &c.

As to the cure, besides making a revulsion by bleeding, blistering, cupping, issues, &c. the diet ought to be moistening and cooling, as lettuce, purslain, sorrel, and spinach: the drink may be an emulsion of the cold seeds, milk and water, clarified whey, &c.

GUTTÆ Serena, barbarously so called by the Latin writers of the lower ages, which the Greeks term *αμαρυσσις*, in medicine, is a total blindness in the principal parts of the immediate organ of vision, the eye still continuing clear and seemingly unaffected.

GUTTERS, in architecture, a kind of canals in the roofs of houses, serving to receive and carry off the rain.

Gutters, with respect to their position, are of two kinds: such as come something near a parallelism with the horizon; and such as incline towards a vertical position to the horizon.

GUTTURAL, a term applied to letters or sounds pronounced or formed as it were in the throat. There are four guttural letters in the Hebrew, viz. *א, כ, ג, ד*, which, for memory's sake, are termed *ahachah*. See **LETTER**.

GUTTY, *Gutti*, in heraldry, a term used when any thing is changed or sprinkled with drops.

In blazoning, the colour of the drops is to be named, as gutty of sable, of gules, &c.

GUY, in naval affairs, a rope used to keep steady any weighty body which is hoisted into, or lowered out of, a ship, or to prevent any thing from being shaken at sea by the agitation of the ship on the waves.

GUZES, in heraldry, roundles of a sanguine or murry colour. These, from their bloody hue; are supposed to represent wounds.

GYMNASIARCH, *Gymnasiarcha*, in antiquity, the master of a gymnasium or place of exercise.

The word is Greek, *γυμνασιάρχης*, and derived from *γυμνασιον*, a place of exercise, and *αρχων*, a head or master.

This office was of great importance, as all the youth were trusted to this master's care to be formed to exercises of the body. He had three officers under him: the *xystarch*, who was master of the

athletæ or wrestlers: the *gymnastira*, who had the direction of all the other exercises; as that they should be performed in due time and properly; that the youth attempted nothing beyond their strength, or injurious to their health: and the *pædotriba*, who taught the exercises mechanically, without understanding their theory.

Under these were several subalterns or servants for the instruction of the youth.

GYMNASIUM, the place where the above exercises were performed, being a public edifice, under proper masters.

The word is Greek, *γυμνασιον*, and is derived from *γυμνος*, naked, as they put off their cloaths, the better to perform their exercises.

GYMNASTICS, the art of performing the several bodily exercises, as wrestling, running, fencing, dancing, &c. See the article **WRESTLING**, &c.

The part of medicine which regulates the exercises of the body, whether for preserving or restoring health, is also termed gymnastic.

GYMNOSOPHISTS, a sect of philosophers who clothed themselves no farther than modesty required. There were some of these sages in Africa; but the most celebrated clan of them was in India. The African gymnosophists dwelt upon a mountain in Ethiopia, near the Nile, without the accommodation either of house or cell. They did not form themselves into societies like those of India, but each had his private retirement, where he studied and performed his devotions by himself. If any person had killed another by chance, he applied to these sages for absolution, and submitted to whatever penances they enjoined. They observed an extraordinary frugality, and lived only upon the fruits of the earth. Lucan ascribes to these gymnosophists several new discoveries in astronomy.

GYMNOSPERMIA, an order or division of the didynamia class of plants in the Linnæan system of botany, comprehending all those plants of that class whose flowers are destitute of a pericarpium or capsule; the seeds being lodged in the base of the cup. The plants of this order are scented, and are accounted cephalic and resolvent, the virtue being principally contained in the leaves; it includes those plants with labiated flowers, such as mint, thyme, betony, &c.

GYNÆCEUM, among the ancients, the apartment of the women, a separate room in the inner part of the house, where they employed themselves in spinning, weaving, and needle-work.

GYNANDRIA, from *γυν*, female, and *ανδρ*, male, the name of the twentieth class of plants in the Linnæan system of botany, comprehending all those whose stamina grow either on the pistillum or upon a receptacle elongated into the form of a style, and carrying on it both the stamina and pistil. All the flowers of this class have a monstrous appearance, owing to the uncommon situation of the parts of fructification,
